The Ludwik Kowalski "Learn Cold Fusion" Website Archive

Dr. Ludwik Kowalski contributed to the cold fusion field in several ways. He created a website that is both a storehouse of information and a complete report on his work in the field. He conducted experiments and collaborated with other researchers. He understood and commented on the sociology of science issues that arose in the rejection of cold fusion.

Dr. Kowalski passed away in October 2021. More information can be found in the memorial obituary "Ludwik Kowalski, Major Contributor to the Cold Fusion," which appears in *Infinite Energy* Issue 159.

Dr. Kowalski's cold fusion contributions and accomplishments are recorded in his "Learn Cold Fusion" (LCF) website. His motivation in creating the website is described on an introductory webpage as follows:

> **About my "learn cold fusion" project**
>
> In the fall of 2002, to my surprise, I discovered that the field of cold fusion is still active. This happened at the International Conference on Emerging Nuclear Systems (ICENES2002 in Albuquerque, New Mexico). Several papers presented at this conference were devoted to cold fusion topics. Intrigued by the discovery I started reading about recent cold fusion findings and sharing what I learned with other physics teachers. I have been doing this over the Internet using Montclair State University website:
>
> https://msuweb.montclair.edu/~kowalskil/cf/
>
> What follows is a set of items posted, more or less regularly, on that website since October of 2002. The items reflect my own process of learning, mostly from articles published by cold fusion researchers. I am still not convinced that excess heat, discovered by Fleischmann and Pons, is real or that nuclear transmutations can occur at ordinary temperatures. But I do think that time is right for the second evaluation of the entire field. I do not believe that extraordinary findings of hundreds of researchers are products of their imagination or fraud. Our scientific establishment should treat cold fusion in the same way in which any other area is treated. Those who study cold fusion do not appear to be pseudo-scientists or con artists. The items on my list are arranged in the order in which they were posted on my website.

The version hosted at Montclair State University, where Dr. Kowalski was emeritus professor, is no longer up to date. The website archive has therefore been included on the Infinite Energy website for completeness and for reader convenience.

The broad coverage of the website demonstrates Dr. Kowalski's in-depth knowledge of the issues and activities of the entire field. It is impossible to characterize the LCF contents briefly, but typical topics are descriptions of experimental approaches, theoretical explanations, reviews of the work of others, discourse with other researchers, attendance at ICCFs, and cold fusion as science rather than pseudoscience.

In general, the articles stand as independent essays. They have references among them and often have subsequent inserts for annotation, such as more insight or further developments. The LCF website consists of a remarkable 416 webpages and comprises over 1800 pages.

About my "learn cold fusion" project

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J. 07043

Return to the clickable list of items

In the fall of 2002, to my surprise, I discovered that the field of cold fusion is still active. This happened at the International Conference on Emerging Nuclear Systems (ICENES2002 in Albuquerque, New Mexico). Several papers presented at this conference were devoted to cold fusion topics. Intrigued by the discovery I started reading about recent cold fusion findings and sharing what I learned with other physics teachers. I have been doing this over the Internet using Montclair State University web site

http://csam.montclair.edu/~kowalski/cf/

What follows is a set of items posted, more or less regularly, on that web site since October of 2002. The items reflect my own process of learning, mostly from articles published by cold fusion researchers. I am still not convinced that excess heat, discovered by Fleischmann and Pons, is real or that nuclear transmutations can occur at ordinary temperatures. But I do think that time is right for the second evaluation of the entire field. I do not believe that extraordinary findings of hundreds of researchers are products of their imagination or fraud. Our scientific establishment should treat cold fusion in the same way in which any other area is treated. Those who study cold fusion do not appear to be pseudo-scientists or con artists. The items on my list are arranged in the order in which they were posted on my web site.

P.S.

What follows is an email message I received recently:

Dear Mr. Kowalski,
Help! My name is XXX XXXXX and I am a sophomore at XXXXX High School. In my chemistry class, I am doing a project on Cold Fusion. I was looking on the Internet for websites on Cold Fusion, and I came across your links to your Cold Fusion items. I was wondering if you could give me some advice or information? I would like to know what Cold Fusion is, [and] how Cold Fusion was started. . . . .

I am no longer comfortable saying that “cold fusion is voodoo-science.” I am a physics teacher; how should I answer questions about cold fusion?

Can a nuclear process be triggered by a chemical process? The answer, based on what we know about nuclear phenomena, is negative. On the other hand many experiments seem to indicate the opposite. These experiments were performed many years after the first evaluation of “cold fusion” was made by our Department of Energy. As a teacher I would very much appreciate a

second evaluation of the field by a panel of competent investigators. What can one do to make this happen?

1) Introducing Cold Fusion to Students

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J.

I think that cold fusion is worth discussing in the context of introductory physics and chemistry courses, even in high school. What follows is an outline on how I plan to introduce cold fusion next time I teach electricity.

1) Let me summarize what we learned last week. We demonstrated that the amount of heat (Q) generated in an electric circuit is equal to U*I*t., where U is the applied voltage, I is the constant current and t is the duration. To verify this we used a calorimeter, a voltmeter, an ammeter and a timer.

2) Now imagine a situation in which someone claims to discover an electric circuit in which Q is larger than U*I*t. How would you interpret this? How can the amount of thermal energy released exceed the amount of electric energy supplied? The only reasonable answer is that some kind of heat-producing process is going on inside the calorimeter. What is the nature of this process? To answer this question one would have to design additional experiments. In 1989 two electro-chemists, Fleischmann and Pons, made a similar claim (1). Additional experiments, however, were far from being credible.

3) Their electric circuit was a little more complicated than a single wire loop in our calorimeter. It was a glass container filled with heavy water in which a small amount of salt was dissolved. Two electrodes were inserted into the container, one made from platinum and another made from palladium. Platinum was connected to the positive terminal of a car battery while palladium was connected to the negative terminal. The current flowing through the electrolyte and the voltage between the electrodes were measured, as we did in our experiment. The entire container, called the electro-chemical cell, was inserted into a calorimeter and Q was measured. The scientists claimed that the Q significantly exceeded the U*I*t. The difference (megajoules), they announced, was much larger than what could possibly be due to any conceivable chemical process.

4) The electrochemical cell connected to a battery can be viewed as a resistor. For example, if I is 0.1A and U=12 V, then R is 120 ohms. Under such conditions the cell would be receiving, in each minute, the energy of U*I*t=72 joules. Part of this energy would be used to produce chemical changes, mostly breaking molecules of water (bubbling hydrogen and oxygen), while the rest would become heat. In other words, the rate of heating should be smaller than 72 joules per minute and not larger. That is why the experimentally observed excess heat was paradoxical.

5) In my opinion the discovery of excess heat, after being verified several times, should have been announced, more or less, in this way: "we know that the excess heat, sometimes several megajoules, is really produced but we have no idea what process is responsible for it." But that is not how the discovery was presented. The two scientists declared, without having any evidence for it, that the process responsible for the excess heat was nuclear fusion of heavy hydrogen. This was an enormous mistake. Nuclear fusion has been studied for decades and it was well known that a neutron or a proton is nearly always emitted from each fusion event. The number of neutrons emitted to generate megajoules of heat would be more than sufficient to kill researchers observing the cell. Numerous attempts to detect the expected large flux of neutrons (emerging from a similar cell) were not successful. It soon became clear that the heat-generating process, if real, could not possibly be caused by what is commonly called nuclear fusion.

6) Some think that discovering an experimental fact without giving some kind of explanation is not a scientific event. I cannot agree with this. Many important discoveries were made long before they were theoretically explained. Finding something that seems to contradict our current knowledge, and being able to convince others that the effect is real, is

always an important scientific event. It stimulates further investigations and, sooner or later, leads to better understanding of nature.

7) Here is how the first thermal manifestation of nuclear energy (2) was described (in 1903) by Pierre Curie and Albert Laborde: "We have discovered that the salts of radium constantly release heat. ..... One gram of radium develops a quantity of heat of the order of 100 small calories per hour. .... The continuing development of such a quantity of heat cannot be explained by an ordinary chemical transformation." After presenting these facts, and after describing the experimental setup, the authors suggested the possibility that atoms of radium either change slowly or have an ability to use "the external energy of unknown nature." They had no way of anticipating ejection of alpha particles (carriers of energy) from atomic nuclei; the existence of atomic nuclei was discovered much later (E. Rutherford, 1911).

8) I suspect that the discovery of excess heat would have been much less controversial if its announcement had not been accompanied by unjustified speculations about fusion and about practical applications of the phenomenon. These speculations, and other factors (described in 3,4,5,6,7,8,9), created a situation in which the discovery itself was prematurely rejected as invalid. Fortunately, a small group of dedicated scientists did not accept the early condemnation of so-called "cold fusion" and continued to study the phenomenon. They finally identified conditions under which any qualified scientist could observe excess heat (10). The situation was very different 13 years ago; at that time success or failure was a matter of luck; sometimes excess heat was observable and sometimes it was not. Fortunately, the experimental situation has improved significantly. But a process, or processes, through which the unaccounted heat is generated, has not yet been identified. Here is an area of science to which some of you may contribute in the future

2) A Typical Experiment

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J.

Return to the clickable list of items

The first publication on excess heat (in the so-called "cold fusion" phenomenon) appeared in 1989 (1). The discovery, and its aftermath, were described in many books (2-8). A typical setup was a glass container filled with heavy water in which a small amount of the LiOD salt was dissolved to make an electrolytic cell. Two electrodes were inserted into the container, one made from platinum and another made from palladium. The platinum was connected to the positive terminal of a power supply while the palladium was connected to the negative terminal. Deuterium ions entered into the palladium electrode (cathode) and diffused to occupy the interstitial positions of the crystal lattice. This preparation process, called loading, is an exothermal reaction (formation of PdD) whose thermal output is about 9,000 calories/mole. The rate at which heat was produced during the loading was small in comparison with the rate of ohmic heating of the cell.

Nothing unusual was taking place at this stage; the current was small and the cell temperature was rising to reach 31 degrees. At that temperature the cell was in thermal equilibrium with its surrounding. After 19 days the atomic ratio of D/Pd was sufficiently high (close to unity) to start the second stage, generation of excess heat. This was probably accomplished by doubling or tripling the voltage between the electrodes. The cell temperature increased to 48 degrees (new thermal equilibrium) and remained high for a long time. During that time the rate at which heat was flowing out of the cell was measured. It turned out to be about two times higher than the rate at which electrical energy was supplied to the cell.

How can it be that the amount of thermal energy released, at any specified time interval, exceeds the amount of electric energy supplied? The only reasonable answer was that some kind of a heat-producing process was going on inside the cell. This unknown process was named "cold fusion." The ability to generate excess heat eventually ended, after about one month. During that time approximately 17 MJ (4.1 million calories) of heat was generated per cubic centimeter of palladium. The authors claimed that this could not possibly be attributed to a chemical process. Attributing it to a nuclear process was certainly premature in 1989.

Ideally one would like to have a process in which excess heat is generated for as long as at least some PdD is left in the cathode. In reality "the energy-out" over "the energy-in" ratio was decreasing progressively till it became less than unity, one month later. This has probably been correlated with the progressive deterioration of the cathode. Note that the thermal output of 17 MJ in one month amounts to only 6.5 watts. Practical applications of the process must wait for the development of long lasting electrodes able to generate heat at significantly higher rates. The mysterious "cold fusion" process must be studied in order to promote possible future applications. Unfortunately, the federal financial support for research in this area has been cut in 1990, mostly due to mistakes made by the early promoters. This, however, did not prevent a small group of researchers (at least one hundred) from exploring the uncharted territory and publishing the results of their studies, mostly over the Internet (9).

Two appendicies for my CF essay

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J.

I am writing a long essay on cold fusion; hopefully it will also be posted on my web site. What follows are two appendces to the essay.

Appendix 1: Three kinds of Cold Fusion</B>

As previously indicated, three kinds of similar phenomena were known in 1989: cold fusion (CF), Muon-Catalyzed Fusion (MCF) and Cluster Impact Fusion (CIF). In my mind the first is associated with a chemist Fleischmann, the second with a physicist S.E. Jones and the third with a nuclear scientist G. Friedlander. It is well known that palladium reacts to hydrogen as a "sponge." One cubic centimeter of that metal can be loaded with up to 900 cubic centimeters (at NTP) of hydrogen gas. In 1960's Fleischmann used palladium to separate isotopes of hydrogen. The cold fusion idea, and the discovery of excess heat, together with Pons, are probably connected with this work. My purpose here is to briefly describe MCF and CIF. A comment about CF is added at the end.

Jones observed muon-induced fusion long before the discovery of excess heat was announced; his work was rooted in ideas expressed in 1948 by F.C. Frank, from England and further developed by A. Sakharov, from the Soviet Union. According to (2) these two scientists were the first to speculate about spontaneous fusion of protons inside muonic molecules. What is a muon? It is a particle whose charge is the same as that of an electron but whose mass is 207 times larger. Discovered though cosmic ray studies, muons disintegrate rapidly after their formation; their half-life is only 2.2 microseconds.

A muon orbiting around a proton constitutes a muonic hydrogen atom. According to Bohr's model, muonic atoms are much smaller than ordinary hydrogen atoms. And molecules made from muonic atoms, either HD or DD, are much smaller than ordinary HH molecules. That is why the probability of fusion in muonic molecules should be much higher than in ordinarily molecules. Eight years later fusion inside muonic molecules was actually discovered by L.W. Alvarez, an American scientist. Sending a man-made beam of muons into containers filled with liquid hydrogen and liquid deuterium he and his collaborators discovered a pattern of tracks which was later identified as long sequences of fusion events in muonic molecules. The researchers were not guided by the speculations of Frank and Sakharov; their data, however, validated the speculations. It turned out that a single muon, during its short life-time, could become a component of many muonic molecules and thus is able to generate many fusion events. The process was named muon-catalyzed fusion, MCF.

Jones found that this process can not be used for practical purposes because the number of fusion events a single muon can generate, in its short life, is too small. The energy cost of producing one muon in an accelerator is much higher than

what could possibly be catalyzed by it. One of Jones' coworkers was promoting the idea that MCF can possibly play a significant role in geological processes. Influenced by that idea Jones wanted to investigate a possibility of what he called piezofusion; nuclear fusion under very high pressures. Can hydrogen nuclei be forced to fusion inside solid materials? This was the same question that Fleischmann and Pons, only fifty miles away, wanted to answer after observing excess heat. Jones' team was able to identify fusion events with a neutron detector (7). But the rate of neutron emission was about ten billion times smaller than necessary to justify the presumably-observed excess heat.

The third kind of cold fusion was studied at Brookhaven National Laboratory (8). Intrigued by the CF controversy, Friedlander and his co-workers accelerated microscopic droplets of heavy water (containing about 1300 D_2O molecules each) to a modest kinetic energy, about 220 eV per molecule, and observed what happens when droplets collide with a solid target. The idea was to test whether or not fusion occurs in a suddenly compressed droplet. The name of the phenomenon, cluster impact fusion (CIF) was given to the process after hot-fusion-like events were identified on the basis of protons and tritons with appropriate energies. Neutrons were also most likely present but the experiment was not set up to detect them.

The only unusual thing about the CIF was the number of fusion events. There were 10^{10} times more such events than one would expect by using the accepted hot fusion theory. The temperature that a tiny droplet could possibly reach, after being stopped at the target, was certainly below 10^5 K. This number is 10,000 times smaller than the 10^9 K needed inside a hot fusion reactor setuo. In other words, CIF fusion rates are also much too high to be consistent with the existing theory of nuclear fusion.

Appendix 2: Why is it so difficult?

The issue of irreproducibility is very serious. It refers to situations in which a phenomenon is observed by some but not by others. Here is how the issue was addressed in (17): "Most scientists hold the view that anomalous effects in deutrated metals can be explained by experimental errors. Some scientists go so far as attributing positive results to self-deception and even fraud and consign this phenomenon to the realms of Langmuir's 'Pathological Science.' Do to the lack of experimental reproducibility, this field remains practically defenseless against such attacks.

To our knowledge, no laboratory can provide detailed experimental instructions to another laboratory and guarantee the reproducibility of the excess heat effect. Nevertheless, considerable knowledge has been gained concerning experimental conditions that favor the excess heat effect. . . Our experiments indicate that the lack of reproducibility is due largely to unknown and uncontrolled variables contained within the palladium stock. ....[Our results] have been used to support both sides of the scientific controversy regarding anomalous effect in deuterated metals. Our first set of experiments conducted over a 6-month period (25 March - 7 September 1989) produced no significant evidence for any excess enthalpy produced. ....[Other groups] also reported no evidence for excess heat, thus greatly impacting the general scientific opinion regarding this field. All three [other] groups discontinued their experiments after only a few months of investigation.

We continued to investigate other palladium samples and eventually observed significant evidence for excess enthalpy from the use of Johnson-Matthey palladium rods. In retrospect, it would be impossible for any research group to adequately investigate the multitude of variables involved with this field in only a few months. These variables range from the palladium metallurgy to the D_2O purity, the type of electrolyte and concentrations, the electrochemical cell, the electrode arrangement, the type of calorimeter, proper scaling of the experiments, the handling of metals, the current densities used, the duration of the experiments, the loading of deuterium into the palladium, the use of additives, and so on." Ironically, this was written in 1996, seven years after the field of cold fusion was declared to be unscientific (1).

A simplified analogy would be a situation in which stars on the dark sky are seen on some nights only. I am thinking about a planet, somewhere in the universe, whose one side is always in the darkness and whose other side is not accessible. People live in darkness and are not aware of the existence of clouds. But they do see stars occasionally and argue about their reality. Does it mean that stars are not real?

4) Three Biographies

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J.

Return to the clickable list of items

These short biographies of Fleischmann, Pons (chemists) and Jones (physicist) were copied from pages 46-49 of E.F. Mallove's book : "Fire from Ice; Searching for Truth Behind the Cold Fusion Furror," John Wiley & Sons, New York, 1991. I strongly recommend this book, and the book of J. Huizenga "Cold Fusion; the Scientific Fiasco of the Century," Oxford University Press, Oxford, 1993, to all those who are interested.

Martin Fleischmann, now a naturalized British subject, was born March 29, 1927, in Karlsbad, Czechoslovakia, to Jewish parents. The family came to England to avoid inevitable persecution by the Nazis. Martin went to high school in Sussex, England, during the war, attended Imperial College in London after the war (1947-1950), and later distinguished himself by achieving at age forty the professorial Chair in Electrochemistry at the University of Southampton. Fleischmann has been called a genuine Renaissance man with a reputation for brilliant and creative ideas -- not all of which pan out, but such is the nature of creativity. Surely, when one listens to or is in the presence of Martin Fleischmann, one feels that the image of an exceptional polymath fits him like a glove.

Since 1986, Fleischmann has been a Fellow of the Royal Society, an honor given only to the most distinguished of scientists. The author of over 200 scientific papers -- a number of them with Pons as collaborator -- and a number of portions of textbooks, Fleischmann won the Royal Society of Chemistry's medal for Electrochemistry and Thermodynamics in 1979. He was president of the International Society of Electrochemistry (1970-1972). In 1985 he was awarded the Palladium Medal (how appropriate!) by the U.S. Electrochemical Society. Fleischmann, married since 1950, is a father of three (a son and two daughters), and a grandfather of four. His leisure interests run the gamut from skiing, walking, and music to an appropriate avocation for a chemist -- cooking. (Those few readers who still may think of Martin Fleischmann as a quack will be happy to know that he lives on Duck Street in a nice English town.)

B. (Bobby) Stanley Pons is about young enough to be a son of Martin Fleischmann. It was mildly ironic that Pons was born in 1943 in the small town of Valdese in the North Carolina foothills, because on the day of the cold fusion announcement, the huge oil tanker Exxon Valdez (same pronunciation as Valdese) was coming to grief on the rocky Alaskan coast. There soon appeared a MacNelly (Chicago Tribune) cartoon connecting cold fusion with the oil spill. An oil-soaked bird adrift on a buoy was remarking to a similarly blackened seal or sea lion, "Any more word on how those fusion experiments are going?"

Pons's Italian Protestant ancestors had fled religious persecution in the old world. Now, less lethally but in some fashion, Stan Pons was about to be assaulted by many members of the scientific community. He would need a lot of stamina to fight back. In his youth, as at present, Pons was very athletically oriented, engaging in track and football. The cold fusion brouhaha immediately took away from his love for skiing, which in calmer times he had pursued in the Wasatch Mountains, sometimes with Fleischmann. Pons was also drawn to the world of chemistry as a child, as many youngsters had also been, encouraged by parent-bestowed chemistry sets and the like.

Pons attended Wake Forest University in Winston-Salem, North Carolina, graduating in 1965, and began advanced studies at the University of Michigan at Ann Arbor. But with his doctorate almost in hand in 1967, he, the eldest of three brothers, left school to work in his father's prosperous textile mills and to manage a family restaurant in North Palm Beach, Florida. Eventually, his love for chemistry drew him back to active science. With the encouragement of faculty at University of Southampton in England, he entered its graduate program in chemistry and received his Ph.D. there in 1978. Martin Fleischmann was one of his professors. After being on the faculty at Oakland University in Rochester, Michigan, and the University of Alberta in Edmonton, Pons came to the University of Utah in 1983 as an associate

professor, becoming a full professor in 1986, and Chairman of the Department in 1988. He has authored or coauthored over 150 scientific publications.

Unlike Fleischmann and Pons, however, **Steven Jones** was well known to physicists and the hot fusion community, which gave him a credibility that Fleischmann and Pons could not match. That Jones came out with a dissimilar but closely related item of cold fusion news at about the same time, ironically, may have boosted the credibility of Fleischmann and Pons in their claims. But there was initial confusion about what Jones was asserting, because of his well-known earlier work on cold fusion of a different sort -- the concept called muon-catalyzed fusion (Chapter 6).

Much of the difficulty that ensued between Fleischmann and Pons on one side and Jones on the othe -- a friction that has now lessened considerably -- can be understood in part from a chasm of personality differences. Jones is the youngest of the threesome, having been born in 1949 and raised a Mormon, with all that his religion's outlook and demanding codes of conduct implies. Jones was a missionary in Europe for the Church of Latter-Day Saints and abides by the faith in not drinking alcoholic beverages, coffee, or tea. He is the father of seven children. His frameless glasses give him an upstanding, almost Boy Scoutish bearing; he speaks in a soft voice and with hesitation at times grinning and laughing frequently. Jones pursues his science with religious fervor, almost literally. His University stationery bears witness, inscribed as it is with the Brigham Young University motto, "The Glory of God Is Intelligence." For about a decade, Steven Jones and his colleagues had been pursuing muon-catalyzed fusion, a technique that they already had shown, experimentally to produce low-intensity fusion reactions at room temperature within a sample of deuterium -- certainly a kind of cold fusion in its own right."

5) The Scientific Process

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J.

Return to the clickable list of items

What follows was copied from J. Huizenga's book "Cold Fusion; The Scientific Fiasco of the Century," Oxford University Press, Oxford, 1993. It is a section (pages 234-236) about violations of the normal rules and procedures of the scientific process in the cold fusion controversy.

"The whole cold fusion fiasco serves to illustrate how the scientific process works. However, seldom do far-out claims receive the amount of national and international attention given to cold fusion. Scientists are real people and errors and mistakes do occur in science. These are usually detected either in early discussions of ones research with colleagues or in the peer review process. If mistakes escape notice prior to publication, the published work will come under close scrutiny by other scientists, especially if it disagrees with an established body of data. The greater the implication of a result, the sooner it will be reexamined. Scientific results, if valid, must be reproducible. When errors are discovered, acknowledged and corrected, the scientific process moves quickly back on track, usually without either notice or comment in the public press.

The scientific process is self-corrective. This unique attribute sets science apart from most other activities. The scientific process may on some occasions move slowly, sometimes even along a circuitous path. The significant characteristic of the scientific method, however, is that in the end it can be relied upon to sort out the valid experimental results from background noise and error. This has been so firmly demonstrated again in the present case by showing that there is no evidence to support the claim of measurable amounts of heat energy coming from room temperature nuclear fusion. True progress must withstand the test of time.

When the news of cold fusion broke, the scientific establishment moved quickly to investigate the validity of the far-out claims which many thought were nonsense. The scientific establishment was not too arrogant to examine room-temperature fusion when it came along, even though it contradicted well-established experimental and theoretical results in nuclear physics. There are occasionally surprises in science and one must be prepared for them. Within the first few weeks after the University of Utah press conference, several multidisciplinary research teams could not replicate any of Fleischmann and Pons' reported claims. Such teams were necessary to investigate quickly the cold fusion claims. Had Fleischmann and Pons formed an interdisciplinary team in their early experiments, cold fusion might have had a very short lifetime.

On the first week of May, cold fusion was the cover story of Time, Newsweek and Business Week, an unprecedented occurrence for a science story. Why did cold fusion generate so much national and intemational excitement? Following the many media stories about the erosion of our environment by the greenhouse effect, acid rain, chemical and radioactive wastes, and the Valdez and Chemobyl disasters, the announcement on March 23, 1989, of the sudden possibility of an abundant, cheap and pollution-free energy source captured everyone's imagination. It was a dream come true, giving us new confidence of our technological competitiveness. Few were concerned or even aware that the University of Utah's publication-by-press-conference released the cold fusion story directly to the public, bypassing all the normal checks and controls of the scientific process. There was no manuscript available for evaluation, there had been no peer review of the science; in fact, the University administrators had not even consulted the nuclear physicists on their own campus. There was only an announcement that watts of excess energy had been produced by a nuclear fusion reaction at room temperature in a small electrolytic cell. The press conference did mention the observation of fusion products to reinforce the claim of nuclear fusion. There was no mention, however, that the fusion product yield was more than eight orders of magnitude less than the claimed excess heat. Later it was shown by others that Fleischmann and Pons made their claim of nuclear fusion before having any solid evidence of having observed any fusion products.

The University of Utah's handling of cold fusion is a striking illustration of what happens when scientists circumvent the normal peer-review process, when scientists use the press as a conduit to disseminate information about a claimed discovery in an unrealistic and overly optimistic tone, when scientists require too many miracles to account for their results, when research is done in isolation by scientists who are outside their field of expertise, when data are published by private communication rather than by those responsible, when administrators use potential royalties to force premature publication and when university administrators lobby for large federal funds before the science is confirmed. Cold fusion is an example of bad science where the normal rules and procedures of the scientific process were violated. One can only be amazed by the number of scientists who reported confirmation of cold fusion by press conference, only to follow later with a retraction or at least a confession of irreproducibility. Reproducibility is the essence of science. It has taken upwards of some fifty to one hundred million dollars of research time and resources to show that there is no convincing evidence for room-temperature fusion. Much of this effort would not have been necessary had normal scientific procedures been followed. The idea of producing energy from room-temperature fusion is destined to join N rays and polywater as another example of a scientific aberration.

The purpose for exposing the cold fusion episode is to show that serious mistakes do occur in science. It is important that we learn from these mistakes. I hope examples discussed in this book will give others new insights into the way science should be done. The general scientific enterprise is vibrant and healthy and has weathered the cold fusion flurry with only minor bruises and scratches. The cold fusion fiasco illustrates once again, as N rays and polywater did earlier, that the scientific process works by exposing and correcting its own errors."

Return to the clickable list of items

What follows is a section copied from pages 221-222 of J. Huizenga book: "Cold Fusion; the Scientific Fiasco of the Century," Oxford University Press, Oxford, 1993. It describes an example of publishing of incorrect data about Cold Fusion.

"Researchers have the responsibility to publish their own experimental data. They should be in a position to explain and defend their results to other qualified experts. This is especially true when the reported data are controversial and directly contradict well-established scientific results in the literature. The description of experiments and results should be published in sufficient detail to give the expert reader the possibility of evaluating the significance of the claimed result. This standard scientific procedure was not followed by University of Utah scientists when reporting large amounts of He in the gases evolving from Fleischmann and Pons' electrolytic cells, supposedly from D+D fusion.

On April 14, 1989, three weeks after the well-known University of Utah press conference, Walling and Simons, colleagues of Fleischmann and Pons, submitted a 'theoretical' paper to the Joumal of Physical Chernistry. In this paper they reported, by way of a private communication from Pons and Hawkins, that the He production in cold fusion cells was even larger than that required to account for all of the claimed excess heat. With this very preliminary and unsubstantiated evidence, Walling and Simons proceeded to construct their three-miracle 'non-theory' described in Chapter 3. At this early stage in the history of cold fusion, He was being promoted as the critical evidence for cold fusion. In the Editorial Comment section (a most unusual addition to a scientific paper) at the end of the Walling and Simons paper, it is recorded that one reviewer stated "it is of utmost importance to get the data presented in this paper into the public domain as quickly as possible." Although I support fast (and accurate) publication, the above advice to publish by private communication data that directly contradicted well-established results in nuclear physics was not in the best long-term interest of science. Authors themselves have the responsibility to publish such findings along with supporting experimental evidence. It is completely unsatisfactory to introduce controversial and potentially important experimental results into the literature through someone else's publication by way of a private communication.

On May 8, 1989, at the Los Angeles Electrochemical Society meeting, three weeks after the submission of the Walling and Simons paper, Fleischmann and Pons announced that their He measurements were flawed. Nowhere in the Walling and Simons published paper (published on June 15, 1989) is this very serious mistake mentioned! The He data, if true, would have been revolutionary. In actual fact, however, these data were completely erroneous, and no retraction has appeared. Presumably, since Pons and Hawkins did not publish their He results, they felt no responsibility to retract the incorrect information put into print by Walling and Simons. On the other hand, Walling and Simons apparently felt that it was Pons' responsibility to set the record straight since they didn't add a note in proof warning the reader that the He data were erroneous. This, of course, would have undermined the entire justification for publishing the Walling and Simons paper. The helium episode is an example of a worst case scenario of what can happen when data enter the scientific literature by way of private communication. When errors are discovered, they should be acknowledged immediately, preferably in the same journal."

7) Pathological Science

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J.

Return to the clickable list of items

". . . On a bus ride from our downtown hotel to the Hahn-Meitner-Institute on the outskirts of Berlin, Wheeler expressed his views to me about cold nuclear fusion by comparing the University of Utah episode with Rene Blondlot's discovery of N rays. As will be described below, the N-ray affair is one of the most remarkable known cases of self-deception in science which affected many French scientists . . . In 1903 Blondlot, a leading French physicist and member of the French Academy of Sciences, announced he had discovered a new kind of rays, which he named N rays, after the University of Nancy, where he did his research. Following the fundamental discovery of x rays by Roentgen in 1895, Blondlot in experimenting with x-ray sources claimed he had found a new kind of emanation. These strange new rays could penetrate inches of aluminum but were stopped by thin foils of iron.

The general properties of N rays were elusive at best. When N rays impinged on an object it was claimed that there was a slight increase in brightness. Blondlot admitted, however, that a great deal of skill was needed to see the effect of these rays. This did not keep a number of other physicists from reporting and extending Blondlot's findings. A large number of papers were published, many arguing that N rays ought to be important because x rays were considered to be one of the most important types of radiation known. N rays do not exist. The many scientists who reported seeing them were the victims of self-deception.

One of the interesting aspects of this episode is the large number of working scientists who were taken in. When the renowned American physicist R.W. Wood heard about these claims, he went to France to visit Blondlot's laboratory and to observe his experiments first hand. Blondlot at that time was using a prism to separate the different components of N rays. In a dark room Blondlot was demonstrating to Wood that he could measure three or four different refractive indices, each to two or three significant figures. The amazing feature of these experiments, as asserted by Blondlot, was that they were accurately repeatable. Wood listened and observed for a period of time, noticing that Blondlot was measuring the position of the beam of N rays to within a tenth of a millimeter. On asking how it was possible to detect the N rays with such great precision, Blondlot replied (as recorded in Physics Today, October, 1989) 'That's one of the fascinating things about N rays. They don't follow the ordinary laws of science that you ordinarily think of. You have to consider these things all by themselves. They are very interesting but you have to discover the laws that govern them.'

By now Wood had correctly surmised that something peculiar was happening. In the darkened room Wood surreptitiously removed the prism and placed it in his pocket. He then politely asked Blondlot to repeat some of the previous measurements, which he was happy to do. With the center piece of the experiment missing, Blondlot obtained exactly the same results. Wood wrote a devastating account of his observations, which was published in Nature, showing Blondlot's N rays resulted from self-deception Wood's expose finished N rays outside France, but French scientists continued to support Blondlot for some years. "

8) Burden of Proof

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J.

Return to the clickable list of items

What follows was copied from J. Huizenga's book "Cold Fusion; The Scientific Fiasco of the Century," Oxford University Press, Oxford, 1993. It is the beginningof the last section (pages 285-287) of the Epilogue. The author is a well knownnuclear chemist; he was the Chairman of the DOE/ERAB panel (Department ofEmergy/Energy Research Advisary Board) which produced a highly critical 1989 report on cold fusion.

“The term ‘cold fusion’ as presently used encompasses a ‘melange’ of claims as discussed in the previous sections of this chapter. The more avid proponents of cold fusion continue to argue that the excess heat in many experiments is so large that the source of the energy must be nuclear fusion or some other unknown nuclear reaction. A fraction of these proponents takes the more conventional point of view and admits that if the process is truly nuclear, there should be a commensurate amount of nuclear ash. The task for these advocates is clear-cut: find the nuclear products. If the reported intensity of nuclear products is orders of magnitude less than the claimed excess heat, then the excess heat is not due to a nuclear reaction process. Furthermore, if the claimed excess heat exceeds that possible by other conventional processes (chemical, mechanical, etc.), one must conclude that an error has been made in measuring the excess heat.

There are, however, many proponents who ignore or deny the fundamental equality between the magnitudes of the excess heat and nuclear reaction products. They cite the unsubstantiated claims of insignificant amounts of neutrons, tritium, helium, etc. to bolster their belief that the claimed excess heat must be nuclear. The latter school of advocates wants to put the burden of proof on the skeptics! They challenge the skeptics to prove that the excess heat is experimental error. What is required, they say, is a modem-day R.W. Wood to rise up and find the critical mistake being made in calorimetry. This, of course, is impossible because the level of absurdity of cold fusion claims has grossly multiplied with time. First, heat was reported to be produced with heavy water and palladium, where light water served as the control. Then it became fashionable to claim even greater success and larger power gains with light water and nickel.

For good measure, element transmutation has also been reported to occur in different media including biological solutions. Even the ultimate dream of the alchemists is claimed, the production of gold from mercury. All of this wishful thinking about nearly-for-free energy has attracted a fringe element of charlatans attempting to promote their own fame and fortune. It is not the responsibility of skeptics to disentangle this web of cold fusion claims ranging from the marginal to the ridiculous. All of these unsubstantiated claims seem to merit the same value to proponents who lump them together as equally-weighted contributions. It is this assorted package of claims that serves as the basis for the oft-heard myth that cold fusion has been verified hundreds of times. No claim is too preposterous to be denounced by the advocates. Any and every result is acceptable under the umbrella of cold fusion. Denial of the equivalence between the magnitude of excess energy and the number of products associated with a nuclear reaction is a rejection of the law of conservation of mass and energy, and qualifies as blatant pseudoscience.

In the final analysis, the burden of proof falls squarely on the shoulders of the proponents of cold fusion. That is the way science works. Advocates must describe their experiments in sufficient detail in publishable papers so that their results can be replicated by knowledgeable scientists. Ten (or some other incommensurate number of) nuclear products per second does not serve as a replication of one watt of excess power. Verification will occur when enough separate and independent replications have been performed so that experienced scientists agree on the outcome. After nearly four years and the expenditure of many tens of millions of dollars worldwide, we still only have unsubstantiated and fragmentary claims of watts of excess heat generated from light and heavy water (and H_2 and D_2 gases) by some

unknown mechanism reported to have a nuclear origin. To this date, not a single, well-controlled and reproducible experiment has been reported where corresponding amounts of excess heat and nuclear reaction products are reliably measured.

This is the current [1993] status of cold fusion. Hence, I conclude now, as I did in July 1991, that the claim that cold fusion is a nuclear process producing watts of excess power, without commensurate nuclear reaction products, is a chimera and qualifies as pathological science (see Chapter 12). At best, the cold fusion fiasco may lead to new information on materials and energy storage, but even this has not been established at this time. Furthermore, there is still no persuasive evidence that any nuclear reaction products have been positively identified in cold fusion experiments in very low level background environments. Regrettably, the idea of producing useful energy from room-temperature nuclear reactions is an aberration. ....."

9) Storms on Scientific Method in CF

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J.

Return to the clickable list of items

The piece below was extracted from an article of E. Storms, as downloaded from < http://home.netcom.com/~storms2/park.html >

The article is a review of a book "Voodoo Science" published by R. Park. Addressing the issue "observations versus theories" Storms wrote: "Science prides itself on resolving conflicts using logic and facts to provide a better understanding of nature. . . [But to Park] the explanation becomes more important than the observation. Because this particular explanation can not be believed, the observation must also be rejected. Thus, a major flaw in modern science is revealed - a Theory is more important than an Observation. The behavior of nature is not real unless it can be explained, especially using conventional concepts. This flaw in logic is at the heart of the book and provides an explanation for rejection of these and other subjects by many scientists.

New discoveries always conflict with some dearly held belief. This conflict when used to reject the claims, prevents new discoveries from being explored and properly explained. This is not to say that all ‘strange’ ideas are correct or that all have a new and worthwhile explanation. Clearly, some should be rejected as being caused by obvious error, fraud, or simple insanity. The problem comes in deciding how much time and resource should be devoted to a search for an explanation and how the resulting facts should be evaluated. ..... If science is to clean up its act, this defect in the approach scientists use needs to be addressed. A clear and extensive discussion of this general problem can be found in the book "Revolution in Science" by J. Bernard Cohen (1985) or "Forbidden Science" by Richard Milton (1994)."

The next piece was extracted for a relatively recent articles of E. Storms, "A Critical Evaluation of the Pons-Fleischmann Effect" Infinite Energy, 2000, #31, p 10. I downloaded this article as the StrmsEacritical.html file from the following web site: < http://lenr-canr.org/Features.htm >

"Many new studies are available to make an objective evaluation of the Pons-Fleischmann effect possible. ... A wide range of observations involving anomalous production of energy as well as nuclear products have been published. While many of the claims are still open to interpretation, the general conclusion is that an important, novel phenomenon has been discovered which deserves renewed interest. Since the claims of Profs. Pons and Fleischmann were announced ten years ago, studies have been undertaken by hundreds of scientists in laboratories of at least nine countries in an attempt to verify what they then called "cold fusion." Some of the results support the idea that the anomalous nuclear reactions can be made to occur in special solid materials. Many more investigations failed to show the claimed effects. Although this body of work is largely unknown to the general scientific community, it nevertheless is believed by many to show the claims to be false.

Ten years of work worldwide have produced over 2500 published papers, many peer reviewed, which have

answered most of the objections leveled by the critics. It is now possible to make a more objective evaluation of the phenomenon than was previously possible. Unfortunately, during this time the claims have been the subject of considerable distortion. The reader is asked to lay aside the emotional reaction 'cold fusion' can generate and read the following arguments with an open mind. ..... Of course, many studies have been poorly done and cannot be used to evaluate the claims either way. Such deficiencies are common in all aspects of science. [In this article] an attempt will be made to determine how well the claims have been replicated and whether consistent patterns of behavior have been revealed. For good reason, these are the techniques science demands be followed when any new ideas are evaluated.

In contrast to these conventional criteria, numerous critics have observed that 'extraordinary claims require extraordinary proof.' This is a very high standard which has prematurely doomed many new ideas to the trash bin, some deserving and some not. We need to realize that potential errors can be found by clever critics in any study, no matter how well done. Hence, a perfect proof is almost impossible to obtain until considerable information has accumulated. Such an accumulation is very slow and difficult if an idea is completely rejected, as has been done in this case. Consequently, at the very least, I would hope that the skeptical reader would entertain a possibility that some parts of the claim deserve further study, even though all important questions have not, as yet, been answered."

That was an introduction to a very long and worth reading article. Let me mention that Edmund Storms is a retired material scientist with a Ph.D. in radiochemistry. Prior to his retirement he worked for 34 years at Los Alamos National Laboratory. His work involved basic research in the field of high temperature chemistry as applied to materials used in nuclear power and propulsion reactors, including studies of the "cold fusion" effect. He was among the first scientists to discover radioactive tritium in electrochemical cells after they were used to produce excess heat.

Over seventy reviewed publications and monographs resulted from this work as well as several books, all describing an assortment of material properties. He presently lives in Santa Fe where he is investigating the "cold fusion" effects in his own laboratory. These studies have resulted in sixteen presentations to various conferences including the ACS and APS. In addition, twenty-one papers have been published including three complete scientific reviews of the field, one published in 1991, another in 1996 and the latest one in 1998. A critical evaluation of the Pons-Fleichmann Effect was published in 2000. In May 1993, he was invited to testify before a congressional committee about the "cold fusion" effect. These biographical details were extracted from < http://home.netcom.com/~storms2/index.html >. Let me quote a letter that Dr. E. Storms sent to the editors of Scientific American.

* * * * * * * * *

November 30, 2002
Editors Scientific American
415 Madison Ave. New York, NY 10017

Dear Sir:
Your analysis in the December issue about why science is neither respected nor understood by the general public I found to be very much to the point. Those occasions when science accepts claims that are later found to be false clearly give science a black mark. Unfortunately, in an effort to avoid such embarrassment, science also rejects claims that are later found to be true. I ask you, which is the greater threat to science and mankind, accepting a claim that can have no possible benefit or rejecting a claim that

can have great benefit?

I could offer many examples of how good ideas have been rejected in the past, but I would like you to consider one very important claim that now has almost universal rejection, yet is supported by a growing body of data. As a scientist, I was trained to judge the reality of nature from good data based on replicated experiments. Yet, I find that the scientific community increasingly bases what is real on the opinions of a few respected journals and academics using theoretical arguments, regardless what is being discovered by other scientists operating in the real world. How is the general public expected to respect science when it does not follow its own stated rules of evidence?

The discovery I would like to use as an example of this double standard is what is called LENR or low energy nuclear reactions. This has also been given the very inaccurate name of cold fusion, a name that now causes rejection and ridicule. This ridicule comes from people who have no understanding about what is now known, yet their opinions are accepted as fact. Is this the way science is supposed to operate?

If you wish to be true to your stated wish to make science more respected, I suggest you educate yourself about this important phenomenon by reading information available at www.lenr-canr.org. There you will find over a thousand publications that support the reality of such anomalous nuclear reactions, as well as several reviews in full text that answer important questions raised by skeptics in the past. Serious scientists rejected ‘cold fusion’ in the past for good reason. These reasons no longer apply. If science cannot correct a past rejection, then what good is the scientific method? Can anyone respect a scientist who cannot change his/her mind after being presented with better data?

Respectfully, Edmund Storms, Ph.D.

10) A Russian Connection

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J., 07043

In October 2002, I attended the International Conference on Emerging Nuclear Energy Systems in Albuquerque. There I met a Russian scientist, Alexander Karabut. He was one of the authors who published an early report (1) on nuclear processes taking place in so-called "cold fusion." Here is what was written about this work by one of the opponents (2) of CF. "Some of the most incredible results were reported by groups from Russia..... [For example, (1). That group reported observing] charged particles with thirteen different energies ranging up to the maximum of 18 MeV, neutrons with energies up to 17 MeV, gamma rays, x-rays of several energies, many radioactive isotopes, palladium fission fragments and an increase in helium concentration in cathodes by mass spectroscopy. Some of the radiation effects continue for times of minutes to hours after the [current] is turned off. … The above Russian results could not be verified in other major Russian laboratories, such as Dubna."

These critical words were written ten years ago. Since then the byproducts of nuclear processes were reported by many groups in several countries. Karabut spent ten years to study nuclear process associated with generation of excess heat. His talk at Albuquerque was the summary of findings. Knowing Russian I helped the author to improve the translation and had a chance to ask for clarifications. Karabut thinks that the scientific establishment in Russia considers cold fusion to be voodoo science. In fact, after returning to Moscow he sent me an interesting book. The author (3) heads the "Commission to Oppose Pseudo-Science and Falsifications in Scientific Research." I had no idea that such a commission has been created by Russian Academy of Sciences. The book ranks cold fusion at the same level as N rays, astrology, extrasensory perception and magic.

Karabut hinted that the antagonism against cold fusion in Russia has more to do with the competition for very limited financial support than with objectivity. I am not in a position to determine the validity of this hint. But my impression of Dr. Karabut was very positive. He graduated from the Soviet equivalent of MIT and worked as a weapons scientist in top secret laboratories (until they were closed after 1990). His main instrument was a glow discharge chamber in which cathodes, such as Pd, could be loaded with deuterium. The maximum voltage used was 1500 V, the maximum current was 100 mA. The chamber was equipped with a very sophisticated flow calorimeter and various detectors. My translation of Karabut's presentation will probably be posted on this web site. For the time being let me summarize their major findings.

1. Alpha particles of 14 MeV and protons of 3 MeV were identified when the cathodes were Pd, Ti and Ni, but not Ta. I like the idea of using the $1/r^2$ law to demonstrate that particles were emitted by the cathode. No charged particles (above the usual background) were detected when an identical experiment was performed with H_2 instead of D_2

2. Gamma rays were studied with a Ge-Li detector. A bombardment of a Pd cathode for about ten hours produced enough gamma activity to be observable (above the background) for up to eight days after

turning the current off. Numerous nuclides were identified on the basis of their characteristic peaks and decay times. In particular all nuclides of the A=101 beta radioactive chain (from Rb to Ru) were present. The first nuclide of this chain has a 31% chance of decaying by emitting a neutron.

3. A large variety of non-radioactive nuclides also appeared in the cathode after it was exposed to D_2 in the glow discharge chamber. Several analytical techniques were used to identify stable elements, including mass spectroscopy. The isotopic composition of iron, produced in the cathode, was found to be very significantly different from what is common in nature (50% of ^{57}Fe near the surface and 30% at the depth of 400 nm, instead of usual 2.2%).

4. The rates at which some of the recognized nuclides are produced are roughly 10% of what be required to match the rate at which the excess heat is generated. In other words, the Russian team tentatively identified some of the non-radioactive "ashes" of the mysterious nuclear combustion process. This is an important finding; absence of “ashes” was often presented as an argument against “slow nuclear burning.”

5. Coherent x-ray radiation, associated with atomic L and M levels of solids, was observed in some experiments.

Such observations, if confirmed, would be extremely significant and I am surprised that they are not used widely as arguments in cold fusion debates. Some of them could be verified using standard equipment available in most nuclear laboratories. A piece of Pd was used as a cathode of a D_2 discharge tube and this resulted in large changes of isotopic ratios of several elements. How could this happen without a nuclear process of some kind? Why doesn’t this happen when D_2 is replaced by H_2? These extremely important questions would have been answered more quickly, I assume, if the area of cold fusion research were not isolated from mainstream science. My own impression is that cold fusion is still blacklisted by the scientific establishment. Why are mistakes made in 1989 still used against honest cold fusion researchers?

11) Bottom Line

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J., 07043

Return to the clickable list of items

What is the main difference between hot fusion and cold fusion communities? In both cases the goal was to build a device whose energy output exceeds the energy input, without consuming chemical fuel. The hot fusion community has been trying to achieve the "break-even" point for five decades and it knows exactly why reaching it is so difficult. The cold fusion community, on the other hand, started by building break-even devices without understanding what was going on and why.

This calls for an elaboration. The hot fusion pursuit started in the 1930's when cloud chambers were used to visualize tracks resulting from d+d collisions. The QM tunneling theory was used to anticipate what should happen at extremely high temperatures; hydrogen bombs confirmed these predictions. Practical attempts to use nuclear fusion for peaceful purposes have been guided by sophisticated theoretical investigations since the 1950's.

The so-called 'cold fusion' pursuit is much younger. It started in 1989 when Fleischmann and Pons discovered that unexplained thermal energy is generated in palladium loaded with deuterium. The first method of loading was electrolytic but excess heat was also observed with other loading methods (for example, by placing palladium chips in deuterium gas under high pressure and in glow discharge tubes). Those who discovered the effect believed in its nuclear origin but they had no evidence. That antagonized many scientists and the entire field was declared unscientific. This opinion prevailed and US funding agencies cut their support for 'cold fusion' research.

Fortunately, many researchers were not discouraged and continued to investigate the phenomenon with very limited means. They soon realized that nuclear processes, if any, responsible for the excess heat in solids, are totally different from those occurring in very hot ionized gases. The field, however, is still treated as pseudo-science by founding agencies. Several theoretical attempts to explain the mechanism of generation of anomalous heat have been undertaken but, so far, none of them has been generally accepted. The entire field is still at the fact-gathering stage. The absence of a theory is not a good reason to disqualify an emerging field of research.

What are the main issues in the CF area? In my opinion they are as follows:

1) The name "cold fusion" is highly inappropriate; it perpetuates an early misinterpretation of the phenomenon. The name anomalous energy (AE), used by many authors, is much more suitable. What is wrong with saying "the AE effect?"

2) All factors influencing generation of anomalous energy should be clearly identified. Great progress has been made in this area, and the reproducibility of experimental results, by qualified scientists, is much better today than it was thirteen years ago.
<P>
3) Experimental evidence for nuclear processes taking place in solids loaded with deuterium is badly needed. At least one such process should be identified and confirmed by several investigators. This is more important, at this early stage, than showing that the rate of the process is commensurable with the rate at which the AE is generated inside a solid. Confirmation of a nuclear process, or of enhanced radioactivity, caused by a chemical structure would already be a great step forward.

12) Physics Teachers Talking about CF

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J. 07043

Return to the clickable list of items

Physics teachers on the Internet list Phys-L, often discus controversial topics and Cold Fusion was not an exception. Prompted by a reply to my recent message (12/10/02) I went to the list archive at:

http://lists.nau.edu/archives/phys-l.html

and started searching for "cold fusion." This produced more than one hundred hits. Unable to read so many old messages I randomly selected some. Let me show them here; they are quite interesting. The names of authors are not shown; authors are identified as teachers. The first message below was a reply to my call for comments about cold fusion. It is followed is my response and then by messages from the archive.

Teacher 1 (12/10/02)
The topic of cold fusion is most interesting but I'm surprised that it is still a topic of current interest on this list-server. I recall that someone reported that cold fusion had been achieved a few years ago but no one has been able to reproduce the effect to this date. However, I thought that most scientists now agree that cold fusion can never be achieved. Is there any new evidence to the contrary .....or is it like the alchemists who spent many fruitless decades trying to turn lead into gold?

Teacher 2 (12/10/02)
I think there exists new evidence for three things:
1) Excess heat is now reproducible, and not only via electrolytic loading. In using electrolytic loading one must be aware that success depends on many factors not known ten years ago.

2) Unusual nuclear processes (emission of nuclear particles and radiation) have been observed in metallic crystals, such as palladium, heavily loaded with D_2.

3) These puzzling processes do not resemble nuclear fusion taking place in high temperature plasma. The ratio of tritons over neutrons, for example, is highly skewed (by many orders of magnitude) in favor of charged particles. Another dramatic difference is that the reported production of ^4He is not associated with the emission of 23.8 MeV photons. For more details see my short essays posted at:

http://blake.montclair.edu/~kowalskil/cf/

and, above all, references which are quoted in my essays. I am only an outsider who tries to learn from experts. It would be desirable if a new panel of experts (physicists, chemists and material scientists) were created by our scientific establishment to evaluate the validity of recent findings and claims. I do not want to be like those who refused to look at what Galileo was showing because, according to Aristotle, such things were not possible. Yes, cold fusion announced in March of 1989 may turn out to be nothing but self-deception or even, in some cases, fraud. But I would like to hear a statement of that nature from honest experts. The first "official" pronouncement (November 1989) should be revised to account for research done since 1990. That is what I think.

Teacher 3 (8/2/02)
When challenging the "laws" of physics there's a right way and a wrong way to go about it. (The same applies to any other activity.)

A1) The rules need changing, and the scientific community handles it well.
A2) The rules don't need changing, and it is handled well. Example: The null results of Eötvös.
B1) The rules need changing, and it is handled poorly.
B2) The rules don't need changing, and it is handled poorly. Examples: N-rays, cold fusion.

And there is a fifth class, where the scientific community responds scientifically but fails to bring the broader society along. Examples: copper bracelet therapy, magnetic bracelet therapy, homeopathic medicines. The task of challenging established ideas is not assigned only to giants like Michelson and Rumford and Rutherford, but also to every worker-bee in the scientific community. To summarize:

-- Primarily we should discuss the right way to challenge the established rules. And the necessity for doing so.
-- Secondarily we should discuss N-rays, cold fusion, homeopathy, etc. as counterexamples, as perversions. We shouldn't call them "positive".

Teacher 2 (12/16/02)

> I am (in general) a rabid anti-conspiracy nut. This promise for
> Cold Fusion is SUCH an attractive possibility that MANY labs
> will immediately jump into the arena as soon as it is established.
> A FEW brave souls will (as we speak) be doing their damnedest
> to get positive results and be among first on the bandwagon. ...

But cold fusion is far from being able to convince others that it is "an attractive possibility." At an early stage a field of science is vulnerable to many things. It has been bastardized prematurely, I think. Whose fault was it? Mostly of those who announced the discovery, and of those who tried to control the discovery by political means. Was it a conspiracy? I do not think so. It just happened this way, unfortunately. I small initial perturbation created a lot of unexpected consequences.

Teacher 4 (7/1/1998)
Teacher 2 makes an important point. The skepticism about "cold fusion" arises not because of any "conspiracy" on the part of "orthodox" science, but rather because literally hundreds of competent scientists have attempted to reproduce the effect without success. The nuclear reactions associated with fusion are well understood, and have well known signatures (reaction products such as neutrons and gamma rays). These have been looked for with the most sensitive of detectors, and have not been found. Since fusion is a nuclear process, it is these nuclear reaction products that carry away the excess energy. If you don't have any nuclear reaction products, then it can't be a fusion reaction that is taking place in these "cold fusion" cells. Rather than taking someone's word for it (even if that someone happens to be Clarke or Schwinger), I prefer to base my own judgments about "cold fusion" on the evidence. And right now the evidence for "cold fusion" is pretty meager, while the evidence against it is pretty strong, at least IMHO.

Teacher 5 (7/1/1998)
I believe that it is nigh-impossible to change people's opinions regarding "Cold Fusion," so I usually am not tempted to dive in and argue about it. When any reversal of opinion requires the losing of face, then reversals of opinion cannot occur in public. Therefore why even try? If "CF" is eventually shown to be valid, then everyone will leap on the bandwagon, but there will be no detailed investigations of the ones who spent years ridiculing the topic. "Who, me? I was always a supporter!" It sure is easy to be on the side that's winning? I hope that I myself, years from now when CF is shown to be entirely bogus, will still have the stomach to read all these old archive files and see what led me into my shameful pro-CF beliefs. I probably won't though. I'm just as human as anyone.

> Isn't this the standard scenario of pathological science? Wild enthusiasm,
> followed by belated skepticism when the confirming experiments don't work,
> followed by increasing paranoia on the part of the original discoverers,

> whereupon the whole thing goes underground and survives on rumors and
> conspiracy theories.

Yes, it suggests that pathological science is a distinct possibility. However, we cannot argue that, since the above symptoms exist, THEREFORE it must be pathological science. There are other alternatives, so the conclusion does not follow. But since pathological science is a possibility, we should be wary and not immediately adopt solid beliefs regarding the reality of LENR (low energy nuclear reaction) phenomena.

> The excuse that they won't make it publish for fear of ostracism just
> doesn't wash. If it really works, and they can demonstrate it conclusively
> (the real thorn in the ointment is that word--conclusively)

Not necessarily. If it really works, yet is a feeble and hard-to-initiate effect, and if it goes against solid theory, then it becomes incredibly difficult to convince anyone that it exists. Rather, the effect itself will be judged to be impossible, and this fact will be used to judge the reliability of researchers: anyone who sees evidence in support of CF is in incompetent researcher (and knowing the reception they will receive if they noise it around that they've seen such things, the they are probably stupid.) If CF papers are constantly rejected by journal editors, and finally some separate CF-only peer review journals come into being, then researchers simply publish their works there. Those who wish, can subscribe. Those who know that CF is a waste of time need never see a paper about it.

> they, and Pons & Fleishmann, will be wealthy beyond their wildest dreams,
> and then couldn't care less about what the scientific community thinks.

Hardly. Only if CF was easily converted from a laboratory curiosity into a major new energy source would wealth and fame be automatic. The researchers who successfully replicate the CF phenomena have had no luck in making the effects reliable, or increasing their scale. (The people at CETI were claiming various successes, but they are a business, and they keep their developments behind a cloak
of secrecy.) The CF effects seem to be critically dependent on microscopic surface processes which nobody understands well. If it was easy, we wouldn't be having this discussion, and "CF" would have been immediately industrialized. That it was not, is evidence either that is doesn't exist, or that it always was a feeble, flaky, poorly-understood effect. In addition, if it is an effect which attracts the wrath of those who dislike the idea that theory-violating anomalies exist, then it is little wonder that the CF field is just where it is today. "Extraordinary phenomena require extraordinary evidence". In other words, we raise the bar for results which go against theoretical expectations, and lower the bar for results which validate known theory.

> In fact, if they did demonstrate it conclusively, and could
> give a rational scientific explanation of what they did, the
> scientific community would embrace them with open arms.

They have no rational explanation. There are many competing theories, but none mesh easily with known physics. I expect that we will see CF-based commercial products long before anyone figures out how the process works. If Pons and Fleischmann are ever embraced by science, it will be after they are safely dead and are unable to remind everyone of the suppression and ridicule which took place.

> Not only would they celebrate one of their own, but these people
> would be the saviors of scientific research, because everybody would
> be eager to fund all kinds of research, hoping to find more of these
> breakthroughs. If you believe all this is going to happen, or that it has
> already happened but is being kept secret for fear of ridicule, they I
> have a bridge up in Brooklyn, that I would like to interest you in
> next time I'm in your neighborhood.

Not kept secret for fear of ridicule exactly. Papers are rejected after peer review, and if most peers have an attitude of "I won't believe it unless you show me incontrovertible proof", then no papers will be published. Do most research

findings require incontrovertible proof? What about the common wry assertion that 90% of the papers found in journals will be shown to be wrong? There is a bias against CF, the barriers have been artificially raised against it.

Now, popular articles with a pro-CF slant, that is another story. Of course editors are fearful to publish such things. Look at the reaction towards them just in this group! Who has the bravery to stand up to that sort of critical response? Few people, if their jobs depend on it. I'm safe, people can attack me all they want and it only damages my ego, not my career or family's income. Actually, it is more than likely that the editor of a magazine already is hostile to CF, and so the fear is on the part of the writers. As a professional science writer, do I dare to damage my reputation by reviewing the latest ICCF conference, or by even mentioning that such conferences are still taking place? I certainly would think twice. Probably much more than twice.

> I believe that Pons & Fleischmann most recently took their operation to the
> French Riviera, where they were working in a lab funded primarily by Sony
> (actually, not a bad investment for them--they put up what is for them
> petty cash for a few years and if it does pan out they are huge winners. If
> it doesn't, they have lost nothing of consequence to them). But I recently
> heard that Sony had cut off their support. Can anyone confirm or clarify
> this information?

I think the lab is no more. I know that Dr. Fleischmann had retired awhile back. They were unable to take their results much beyond the hard-to-replicate "laboratory curiosity" stage they initially started with.

Teacher 6 (9/20/1999):
I enter this discussion with great fear, but I can't help getting this out of my system. (1) Can we agree that there can be a small amount of muon induced fusion in a tabletop experiment, but not enough to make significant temperature changes? (2) Can we agree that the other types of cold fusion that are being discussed require us to violate Coulomb's Law and therefore are unlikely to occur?

Teacher 7 (9/21/1999):
First of all, just because someone says 'a new result is only accepted if there is at least a plausibility argument advanced to support it' doesn't make it so. You don't have to look any further back than the announcement of high-Tc superconductors to see that such is not the case. When the announcement was made, no one had any theoretical explanation for how it could happen. The BCS theory only applies in metals with free electrons that can be paired up, not in ceramic insulators. But, the claim was made that these ceramics could be made superconducting at much higher temperature than the highest known metallic superconductor. What was the reaction of the physics community? Not to say, 'Oh that doesn't fit our neat BCS theory, so it must be wrong.' No, it wasn't that at all. Large numbers of groups rushed to their labs to try it out to see for themselves if it worked. And, lo and behold, it did work! To this day, as far as I know, there is no satisfactory explanation of the effect. Even John Bardeen himself was unable to come up with an explanation. But it works, and the alloy combination has been modified to tweak the temperature up to nearly 100 K. I expect that some day someone will hit on a way to explain the effect, but the lack of a theory has certainly not been a restraint on people utilizing the effect. There are commercially available kits to demonstrate high-Tc superconductivity in probably every physics department in the country.

On the other hand, when CF was announced, hundreds, literally, of groups went to their labs to try and replicate the effect. Unfortunately, not enough information was given in the press conference to know all the conditions that were used. One group, at Ohio State, wore out a video tape they had obtained of the press conference, looking at the apparatus, comparing the size of the hands in the pictures, etc. Many meetings and conferences were held, the hundreds of groups reported mostly negative results, while a few reported sporadic positive results. These were hailed as having done it right, the others as having done it wrong. The bottom line, for me at least, is that no prototype energy producing device has been forthcoming. In other words, there still is no water heater.

There is a lesson in the CF business. One should not let dollar signs cloud your ability to be objective about your work. And be sure you have your ducks all in a row before you start shooting. P&F gave their first scientific paper on CF at a chemical society meeting in Dallas, (not even to a bunch of physicists) and were asked the two most obvious questions:

1) have you integrated the power input to the cells over the duration of the experiment to be sure you have net excess energy (they had not), and 2) what happens when you do the experiment with ordinary hydrogen (that experiment was only in process, and seemed to give the same effect, so they weren't going to talk about it). Eventually they blamed physicists for being severe critics, but it started with chemists. Carl Sagan said something that I think has been quoted on the list before: "I believe that the extraordinary should be pursued. But extraordinary claims require extraordinary evidence." I hope cold fusion does pan out some day. But you really can't blame people who have tried it and found nothing for being skeptical. And it is not just a matter of dismissing it out of hand because there is no theory to back it up.

Teacher 8: (9/19/99):
> This is a valid problem: Conflict of Interest in those who render
>judgment upon a new discovery. "Don't put the foxes in charge of the
>chicken coop." Who should judge whether CF is valid? Most hot-fusion
>professionals are in danger of emotional bias. Scientists are human, so
>they'd better not go around declaring that they can control their biases.
>If the CF phenomenon is genuine, then it means that the staggering amounts
>of money put into Tokamak-style fusion might have been wasted. It means
>that hundreds of people devoted their careers to a technology which might
>prove of little worth should electrochemical-fusion result in efficient
>reactors. Obviously the pressures on such people would be tremendous.
>They would have to be literal *saints* to not be affected by it. If they
>are normal, non-saintly humans, then they would be in danger of succumbing
>to tricks of their subconscious, such as conveniently finding strange
>justification and weak excuses to dismiss CF as unreal, and they would not
>even know that they were doing this. It would seem perfectly sensible at
>the time, yet future historians would see something entirely different.

And likewise for the CF proponents. What they lack in time and money expended they make up for with pride and the desire to retain professional respect in a field marred almost from the get-go. The earliest proponents of CF were the worst of all possible foxes in charge of the chicken coop. Everyone since has labored under this cloud and they are mostly in the unenviable position of "put up or shut up," a virtual death sentence of many things science in today's research atmosphere.

>In all my reading of CF literature, I've not encountered any "conspiracy
>theory" stuff. In the "perpetual motion" and "antigravity" crackpot
>fields the situation is far different. There it's rare to find a
>researcher who DOESN'T accuse government or industry (or Space Aliens!) of
>suppressing the research. When the crackpots start discussing
>antigravity, it's an effective (though dishonest) tactic to bring up
>conspiracies. The crackpots will launch into paranoid tirades and destroy
>their own credibility.
>
>But try the same with Cold Fusion people, and it is not *their*
>credibility which comes into question. Cold Fusion requires serious
>brainpower and facilities before any research can be done. Cold Fusion
>supporters are professional physicists and engineers, not weak-minded
>basement inventors who, once disparaged, will STAY disparaged.

With the possible exception of the two that put it on the map: While Pons' "partner in crime" has perhaps gotten some unfair coverage, Pons himself was the original apparently-respected researcher who could not sort out conflict of interest, who could not stand the thought of being corrected (much less being wrong) and who could not stand up to the political machine that took over. Had CF followed the path set out by Jones, it would not be where it is today. This statement is one of those double-meaning statements recently discussed in the "recommendations" thread. If Jones had his way, there would not be much promise of virtually unlimited "table-top" energy. It is clear that Jones did not have

his way, and yet there is still not much promise of virtually unlimited "table-top" energy. Given this outcome, it seems that an original approach of slow methodical unheralded peer-reviewed research would have been better for the entire CF field.

>...perhaps CF truly is bogus, and the outcast status of the "CF research
>community" is entirely proper. I myself look at the evidence and decide
>that CF has about a 95% chance of being real. Does that make me a
>"believer"? Of course not. A "believer" believes, and evidence be
>damned. Just as disbelievers disbelieve, and evidence be damned.

To paraphrase, I myself look at the evidence and decide that CF has about a 5% chance (or less) of being real. Does that make me a "disbeliever"? Of course not. A "disbeliever" disbelieves, and evidence be damned. Just as believers believe, and evidence be damned. Although I previously stated that I am a "disbeliever," this was merely to draw a comparison.

Rather, I am extremely skeptical. I was a graduate student in solid state physics at the University of Utah when the story broke, and I was acquainted with several behind-the-scenes people involved (though not PF) in the early days, including Salamon and others. I also had the luxury of just sitting back and observing what was happening. Not long after, I was fortunate enough to be able to witness seminars given by Jones at the University of Utah, only a short drive from his lair. And unfortunately, I and my peers were likely the first grad students on this planet subjected to quantum mechanics homework problems involving CF, from a professor who had been sitting in on telephone conferences and chalkboard discussions literally in the first hours of the story. No more going to look the answers up! :-(

As it did then, the community will ultimately decide the validity, interim and final. Truly. And those who have purposefully impeded the advance of science on both sides of the question will ultimately have their comeuppance. PF have already *rightly* had their comeuppance. Others have followed. Others will follow. And the rest will survive with reputations validated or revived.

Teacher 8 (9/22/99):
>First of all, just because someone like Teacher 8 says 'a new
>result is only accepted if there is at least a plausibility argument
>advanced to support it' doesn't make it so. You don't have to look
>any further back than the announcement of high-Tc superconductors to
>see that such is not the case.

It was not my intention to imply that nothing can proceed without at least a plausibility argument (if not more). My point, admittedly not well presented, was that experimental results, in order to be peer-reviewed published, generally require more than a vacuum of discussion. If nothing else, such results, to be published, at least require a discussion of how or why current theory might be inadequate to explain the results, if that appears to be the case. Rondo further pointed out a crucial requirement in the particular case of anomalous result: that any published work of this nature, peer-reviewed or not, provide great and specific detail regarding the duplication of the measurement, so that everyone can literally rush to their labs to try it, with more to go on than the proverbial video tape. At times there exists an uneasy truce between theory and experiment. A comparison of the examples of high-Tc superconductors and cold fusion will probably make for interesting reading some day, in the annals of social studies.

13) A Brief Introduction

Ludwik Kowalski
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043.

Return to the clickable list of items

What follows is a paper on what used to be called, quite inappropriately, Cold Fusion. Several names have been proposed to replace this misleading name. My own preference evolved toward anomalous energy (AE) phenomena. This name focuses on the unexplained energy puzzle without trying to impose a premature interpretation. I am still not certain that AE is real but I think that scientific papers, including the one below, should be validated scientifically. I met the author of the paper at the International Conference on Emerging Nuclear Systems (ICENES2002) and became interested. He is a Russian scientist who has been conducting AE experiments for more than a decade. Two of his presentations have been published (1,2) in the ICENES2002 report.

As a Russian speaker I was able to help the author improve his presentation in English, a language in which he is far from fluent. We talked about his paper before it was formally presented, and we discussed it afterwards. What I heard in Russian was much clearer than his English translation. That is why I decided to improve it and asked the author to send me the original Russian text. He did this and I paraphrased it. The goal was to improve the readability of what may turn out to be a very significant scientific contribution. The text that follows is based on the original Russian paper, on conversations with the author and on what was presented at the conference. Naturally, I tried to stay as close to the original as possible. The author made several corrections and allowed me to make the paper available over the Internet. A large number of relatively recent articles about the AE phenomena are now available (3).

Claims made in the article are highly unusual and I am puzzled. Will Dr. Karabut's experimental findings, said to be ~100% reproducible, be confirmed by other competent scientists? I do not know; I am a physics teacher and only a part-time nuclear researcher. It was a great challenge to learn and to write at the same time.

Abstract:

The described experimental results, based on (1), describe processes associated with the excess heat generated in a deuterium discharge chamber. A calorimetric method was used to demonstrate that thermal energy produced in the chamber can exceed the electric energy supplied to it by as much as 10%. The excess energy is attributed to nuclear reactions taking place near the surface of the palladium cathode bombarded by positive ions of very low energy (0.5 to 2 keV). The process is accompanied by the emission of protons (3 MeV), alpha particles (14 MeV), soft X-rays (up to 100 R/s) and the production of heavy nuclides (at the rates of up to 10^{13} atoms per second). Most of the results were statistically significant and 100% reproducible.

1) Excess Heat Measurements in a Flow Calorimeter

The apparatus used in these experiments consisted of a chamber pumped out down to 10^{-3} Torr and filled with hydrogen or deuterium up to 10 Torr (see Figure 1). The glow discharge was established between parallel plates, palladium-covered cathode and a Mo anode, separated by several milimeters. Other cathode materials, and other gases, were used in control experiments. The cathode, the anode, and the body of the chamber were water-cooled using three independent circuits. Each circuit was equipped with two thermoresistors, one at the input and one at the output, plus a flow meter.

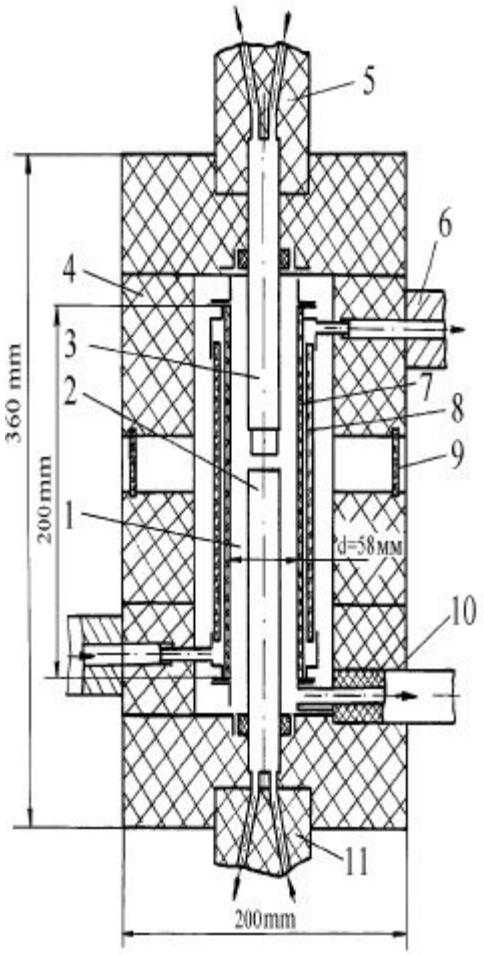

Figure 1 (left): The glow discharge chamber used as a continuous flow calorimeter. (1, the discharge chamber; 2, cathode unit; 3, anode unit; 4,thermal insulation cover; 5, insulation of the anode cooling system; 6, the chamber cooling system; 7,the discharge chamber tube; 8, the chamber jacket tube; 9, windows in thermal insulation cover; 10, the vacuum hose; 11, insulation of the cathode cooling system.)

****

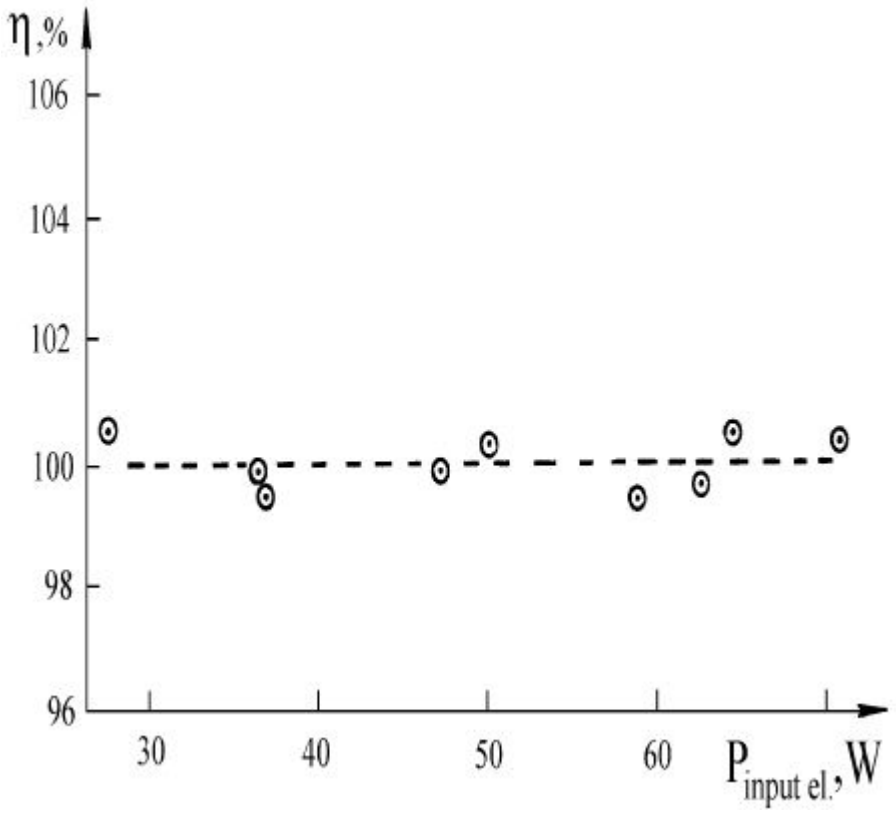

Figure 2: Results of calorimeter calibrations. Nearly 100% of electric energy supplied is removed as heat when the current was flowing through ohmic resistors placed inside the chamber.
****

The heat excess rates, that is, differences between the thermal output wattage and the electrical input wattage, were measured using the Pd cathode in the deuterium gas. The results are shown in Figure 3a. The heat excess rate depends on the following parameters: current density in the discharge chamber, applied voltage, duration of current impulses (t) and duration of intervals between the pulses (T-t). Note that T is the period of repetition, the inverse of the frequency, from 100 up to 1000 Hz, of the electric pulse generator. The value of excess wattage tends to increase with input wattage. Note that excess power also increases with the time between the current pulses, (T-t). This indicates that releases of heat in the cathode continue to take place after the current is turned off (that is, between the consecutive current pulses). The largest excess of power takes place when the difference of potential is between 1000 and 1400 volts; further increase in the voltage results in a rapid decrease of the excess power.

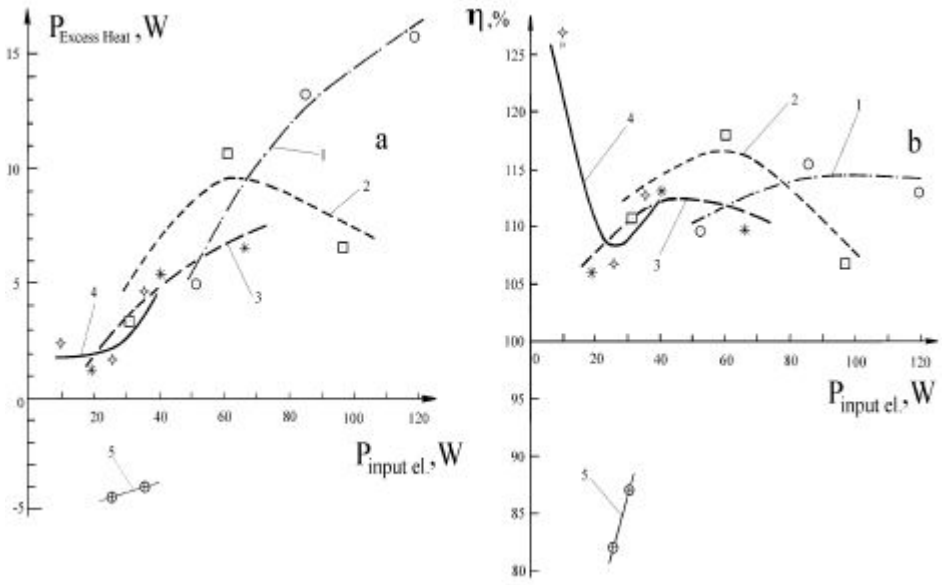

Figure 3 (left): Excess heat power versus the electrical input power for the palladium cathode in deuterium at the pressure of 10 Torrs. The distance between the anode and cathode was 11 mm. Different curves in correspond to different duty cycles of the electrical power supply.

Figure 3b (right): Heat removed as a percentage of supplied electric energy. Different curves correspond to different duty cycles of the electrical power supply.
****

Each curve in 3a or 3b corresponds to a different value of t/T, where t is the duration of the current pulse and T is the period of repetition. The curves labeled as 1,2,3 and 4 correspond to t/T being 0.22, 0.16, 0.11; and 0.054, respectively.

At some pressures (inside the discharge tube) the power excesses were found to be negative, as shown above (curves labeled as 5). Further investigations revealed that this is accompanied by a laser-like emission of X-rays, to be discussed later.

In several reproducible experiments the total measured energy released from the palladium cathode was 4 MJ during the total time of 120 hours This amounts to a mean rate of excess heating equal to 9.2 W, as illustrated in Figure 4.

Measured excess heat rates could not possibly be attributed to a chemical reaction inside the chamber. The slight decrease of the excess power was most likely associated with the progressive deterioration of the palladium cathode.

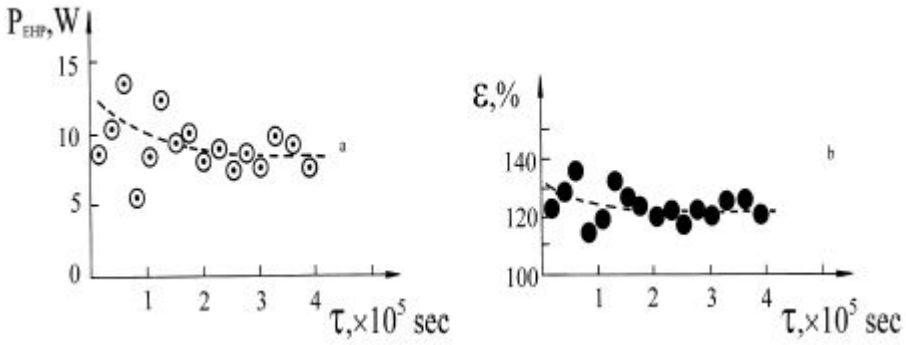

Figure 4a (left): Dependence of the excess heat power on the duration of experiments. System Pd-D_2; t/T=0.13, current 220mA.

Figure 4b (right):): Same system as in 4a. Dependence of the total heat removed (expressed in terms of percentages of input power) on the duration of experiments.
****

2) Registration of Charged Particles
Protons and alpha particles were observed in a setup with a displaced anode, as indicated in Figure 5. They were counted by using plastic track detectors (purified CR-39, Fukuvi Chemical Industry, Japan). The methodology of detection was similar to that used in testing for radon. The observed average rates of emission turned out to be between

10 and 15 particles per second (up to 250 tracks per square centimeter of the detector area and per 6 hours). Some of the detectors were positioned to see the cathode, others were used to determine the background radiation inside the apparatus. Detectors were wrapped in protective Al foils of thickness between 11 and 33 microns. Protons with energies up to 3 MeV, and alpha particles of 14 MeV, were detected in experiments with the Pd, Ti and Ni cathodes (but not the Ta cathode) exposed to the deuterium plasma. The dependence of the number of tracks on the distance from the cathode, r, was found to be consistent with the $1/r^2$ law.

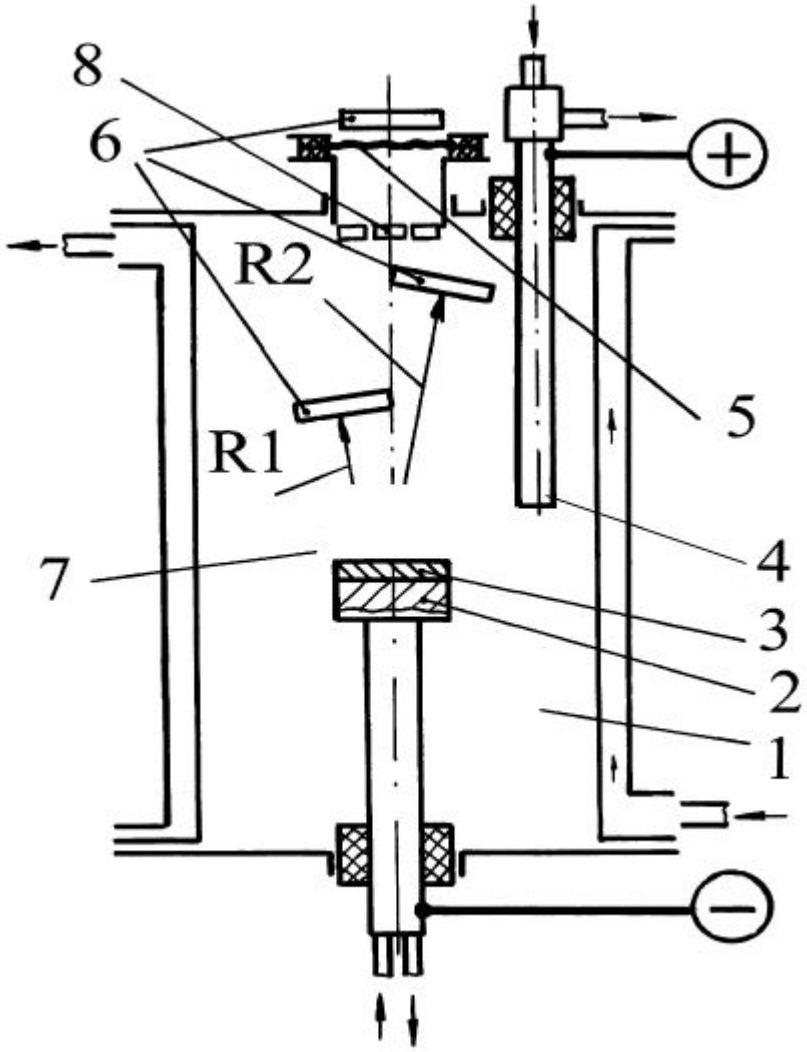

Figure 5: Experimental setup to study emission charged particles and x-rays. (1, discharge chamber, 2, cathode holder; 3, cathode, 4, anode, 5, beryllium window; 6, CR-39 track detectors; 7, glow discharge region; 8, TLD detectors.)
****

A control experiment with the Pd cathode and ordinary hydrogen showed that the density of tracks in the detectors exposed to the cathode was essentially the same as in the background. In other words, protons seemed to be emitted from the Pd cathode exposed to the D plasma but not exposed to the H plasma, as illustrated in Figure 6. The left side graphs show distributions of proton track lengths in D plasma (each for different thickness of Al foils) while the right side graphs show corresponding distributions in the H plasma. As previously indicated, tracks recorded in the H plasma can be viewed as the background not associated with the processes inside the cathode.

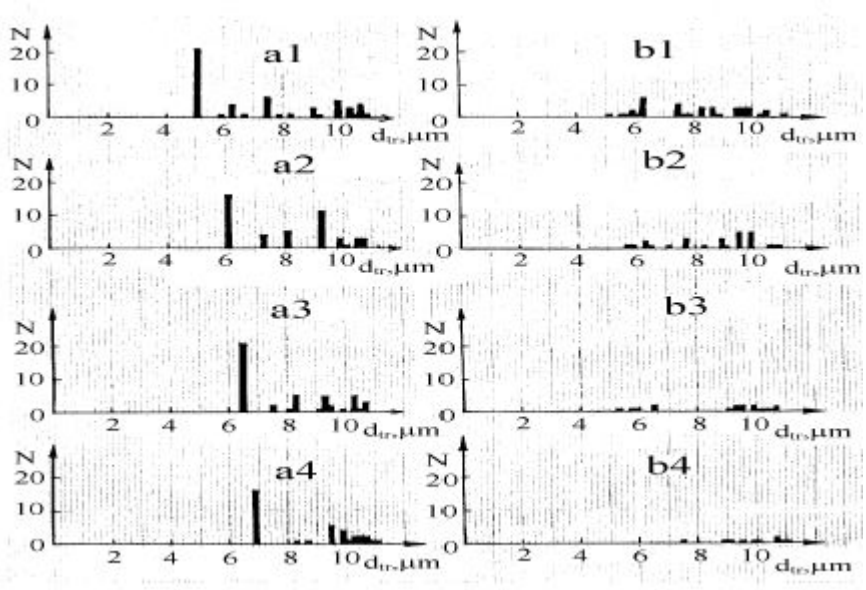

Figure 6: Distributions of lengths of tracks in the CR-39 detectors recorded in the deuterium plasma (left side spectra) and in hydrogen plasma (right side spectra). The protective covers were: 11 microns of Al for a1 and b1, 11 microns of Al plus 60 microns of polyethylene for a2 and b2, 22 microns of Al plus 60 microns of polyethylene for a3 and b3, 33 microns of Al plus 60 microns of polyethylene for a4 and b4. The left side spectra (in deuterium) were collected in ten hours of discharge while the right side spectra (in hydrogen) were collected in five and a half hours of discharge.
****

The rates at which alpha particles and protons are emitted, at different voltages, and at two different currents, are shown in Figure 7. Note that the dependence of Dn (particles per second in all directions) on the discharge voltage is more or less exponential. The recorded rates, however, are much too small to be responsible for the observed excess heat power. It is conceivable that protons are associated with DD reactions; the emission of 14 MeV alpha particles remains a mystery.

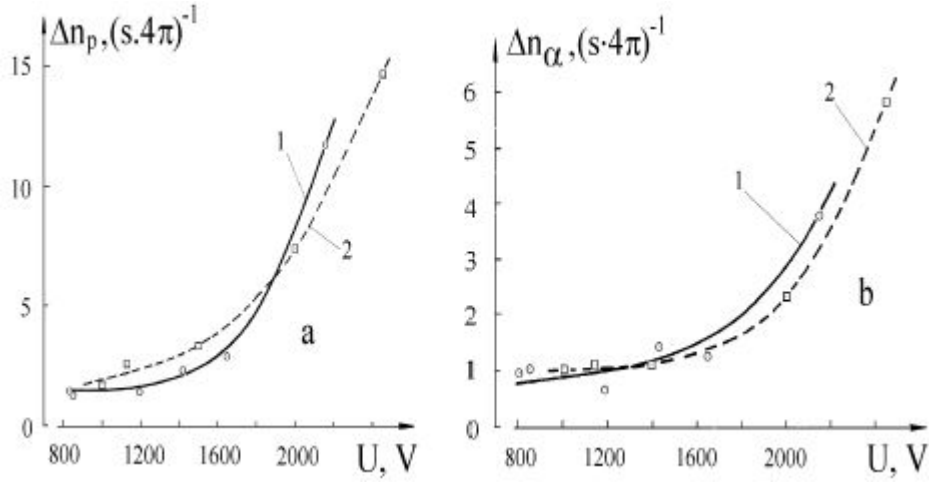

Figure 7a (left): Emission rates of 3 MeV protons at different discharge voltages. 1, for the discharge current of 220 to 300 mA; 2, for the discharge current of 370 to 450 mA (Ti cathode in D_2).

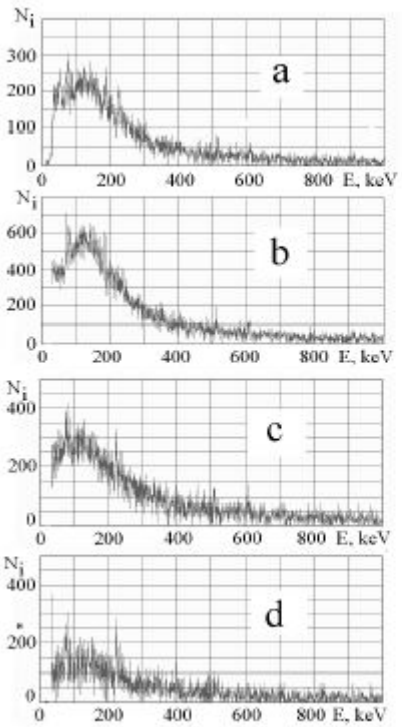
Figure 7b (right): Emission rates of 14 ± 3 MeV alpha particles at different voltages. 1, for the discharge current of 220 to 300 mA; 2, for the discharge current of 370 to 450 mA (Ti cathode in D_2).

****

3) Registration of Gamma Rays.

A Ge-Li detector connected to a multichannel analyzer was used to detect gamma radiation between 0.1 and 3 MeV. To reduce the outside background, the detector and the chamber were shielded by 10 mm of lead. Numerous radioactive isotopes responsible for the emission of gamma rays were identified on the basis of characteristic spectral lines. Gamma ray spectra, recorded during the discharge, and at different times after the discharge, are shown in Figure 8. In a typical experiment the discharge was turned off after tens of hours of the exposure to plasma and gamma rays could be observed for up to eight days before being reduced to the background level. The gamma ray background spectra were recorded during prolonged time intervals (up to several months) between the experiments (starting 10 to 14 days after turning the discharge off). The duration of a background recording could be as short as one hour or as long as 65 hours; fluctuations of background spectra were less than 10%.



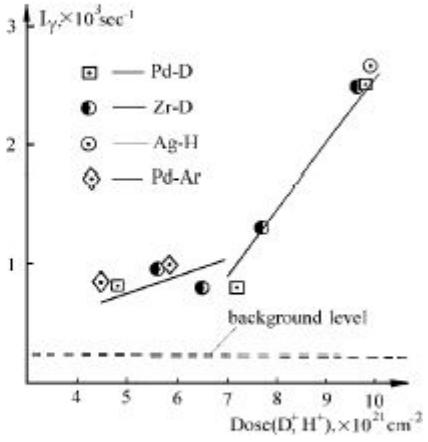


Figure 8 (left): Progressive decrease of gamma radiation after ending an experiment in which a palladium cathode was exposed to the deuterium plasma. The (a) spectrum a was recorded during the discharge, the (b) spectrum was recorded one day after turning the discharge off; the (b) spectrum was recorded two days later; the (c) spectrum was recorded six days later; the (d) spectrum was recorded eight days later.

Figure 9 (right): Dependence of the intensity of gamma rays (at the end of an experiment) on the total number of current ions per unit area. Different symbols are used to distinguish four different combinations of cathode and gas, as labeled.

****

The recorded counts per second were subsequently converted into absolute gamma ray intensities, I, expressed in counts per second, in all directions. This was done by assuming that the distribution of gamma rays is isotropic, by taking into account the geometry and by using known detector's efficiencies. The dependence of I on the exposure to plasma, immediately after a discharge, is shown in Figure 9. Note that the exposure to plasma is expressed in terms of numbers of ions per unit area. The dependence is more or less exponential and, surprisingly, not very different for the four cathode-gas combinations (Pd in D, Zr in D, Ag in H and Pd in Ar).

Groups of radioactive nuclides of half-lives ranging from 1 to 8 days were identified in the Pd cathode after its exposure to the D plasma for 8 days. The spectra shown in Figure 8 were analyzed in terms of two components: peaks and continua. The peak component exceeded the background by a small delta factor ranging from 2.5 to 5, depending on peaks. The continuous component, on the other hand, exceeded the background by a delta factor ranging from 8 to 10. The analysis of data, based on (2), led to the conclusion that gamma rays are emitted from the neutron-deficient (and thus beta-radioactive) nuclides with atomic mass numbers ranging from 16 to 136. In particular, all products of the following A=101 chain:

Rb -> Sr -> Y -> Zr -> Nb -> Mo -> Tc -> Ru

were identified on the basis of numerous peaks, as summarized below. The numbers shown are peak energies in keV.

Rb/Sr	Sr/Y	Y/Zr	Zr/Nb	Nb/Mo	Mo/Tc	Tc/Ru
111.6	128.3	98.3	119.3	157.5	119.9	306.85
271.6	163.4	118.7	140.6	180.7	533.5	545.06
251.6	474.1	216.9	373.9	276.1	590.9	623.8
363.1	510.7	133.8	597.8	280.2	1012.5	489.1
92.8	590.4	104.4	597.8	294.6	713.0	344.0
	232.7	666.6	146.9	722.2	466.3	1599.3
	1091.8	694.3	661.8	912.2	810.8	1590.1
	1362.9	744.1	668.7	1095.8	797.1	1759.8
		1124.8	729.7	1924.5	1042.6	2032.1
		1062.9		2009.5		2041.2
				2565.4		1957.6

It is remarkable that the first three nuclides are known emitters of fast neutrons (31%, 2.37% and 1.94% respectively) and that all gamma lines associated with the above A=101 chain were actually identified in the recorded spectra. Rates of production of various nuclides were calculated from the areas below the peaks on the basis of known efficiencies of detection. The beta radioactive chains of A=16,17, 23, 30, 46, 47, 51, 54, 55, 58, 63, 64, 71, 75, 80, 84, 92, 97, 99, 100, 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 118 and 123 are main contributors of the observed gamma rays. The rates of production of gamma-radioactive atoms did not exceed 10^5 per second. Most of the atoms produced in the cathode turned out to be non-radioactive, as described in the next section.

4) Accumulation of Trace Elements.

Assuming that most of the excess heat is associated with nuclear reactions taking place in the cathode, the material near its surface was often analyzed after prolonged discharges. Average rates of accumulation are displayed in Figure 10a. The horizontal dotted lines refer to the average rates of emission (of these nuclides) needed to produce the excess heat rates of 10 W and 1 W, as indicated. Drastic alterations of isotopic ratios were discovered as illustrated in Figure 10b. The percentage of ^{13}C, for example, changed from about 1% (natural) to about 20% (due to the discharge). Asterisks refer to absent isotopes. The ^{58}Ni isotope, for example, whose natural abundance is nearly 68% was not found among the trace elements produced during the discharge.

The methods used were: secondary ion mass spectrometry, secondary neutral mass spectrometry and spark mass spectrometry. The first method consisted of the following procedures: removing the outer defective layer of 1.5 nm by plasma etching and scanning the 5 nm layer to determine the concentrations of trace nuclides. Then a layer of 100 nm

was removed and another layer of 5 nm was scanned. The procedure was repeated two more times to study the distribution of trace nuclides up to the depth of 400 nm. In one case, for ^{57}Fe, steps were considerably shorter than 100 nm, as illustrated in Figure 11. The absence of ^{58}Ni, ^{70}Ge, ^{73}Ge, ^{113}Cd and ^{116}Cd isotopes, and high abundance of ^{13}C, ^{57}Fe and ^{48}Ti isotopes, seem to be typical of processes contributing to generation of the excess heat.

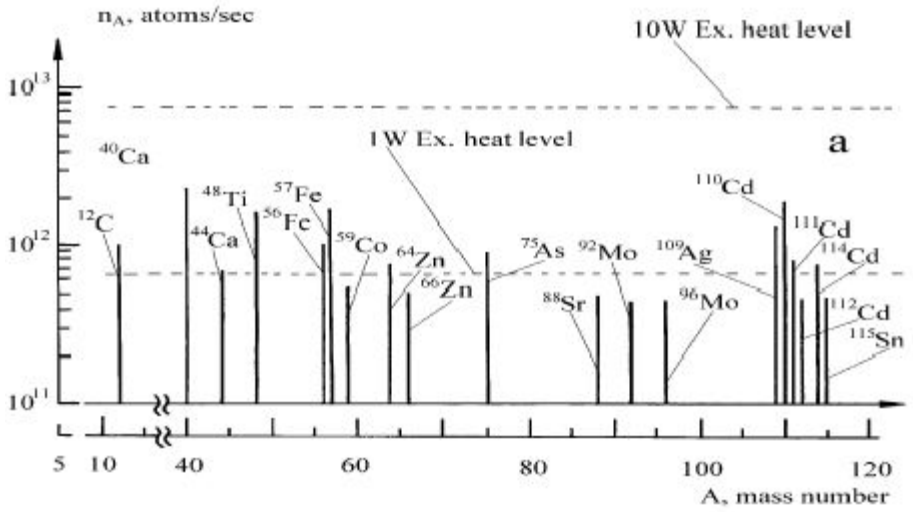

Figure 10a : Average rates of acumulation of different trace nuclides produced in the 100 nanometer layer of the palladium cathode bombarded by deuterium ions. The average current (during the four hours) was 100 mA.
****

These data were obtained after the four-hour Pd-D discharge at the current of 100 mA and pressure of 10 Torrs. The natural concentration of ^{57}Fe is known to be 2.2% while the observed concentrations were found to be much higher. They changed from 50%, near the surface, to about 30% at the depth of 400 nm. Strongly "unnatural" isotopic ratios were found in other trace elements, as illustrated in Figure 10b. Many naturally abundant isotopes, such as ^{58}Ni, ^{70}Ge, ^{73}Ge, ^{74}Ge, ^{113}Cd and ^{116}Cd, were simply not present.

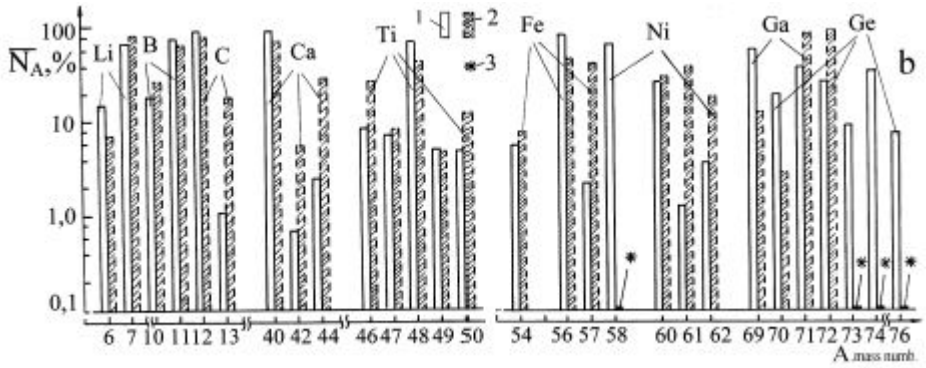

Figure 10b: Crossed bars show percentages for some isotopes at the end of one four-hours-long bombardment of a palladium cathode by deuterium ions. These can be compared with the adjacent left-side bars (clear) referring to natural isotopic percentages. Difference between heights of adjacent bars illustrate isotopic anomalies resulting from the bombardment of Pd by deuterium ions.

****

Absolute concentrations of trace elements were obtained by subtracting concentrations found in the unused palladium from the concentrations found in the cathodes exposed to the deuterium plasma. The elements accumulated in the exposed cathode could be subdivided into three groups: those whose atomic masses were close to Pd, those whose atomic masses were approximately two times smaller and those whose atomic masses were below 40. The identified isotopes, those whose abundance was higher than 1%, were: ^{7}Li, ^{12}C, ^{15}N, ^{20}Ne, ^{29}Si, ^{44}Ca, ^{48}Ca, ^{56}Fe, ^{57}Fe, ^{64}Zn, ^{66}Zn, ^{75}As, ^{107}Ag, ^{109}Ag, ^{110}Cd, ^{111}Cd, ^{112}Cd and ^{114}Cd. Most of them were found in the first 100 nm layer of the cathode. The rates of production of these isotopes, shown in Figure 10a, were estimated by dividing the total number of accumulated atoms by the duration of the experiment, 20,000 seconds. It seems that nuclear reactions producing ^{12}C, ^{44}Ca, ^{48}Ti, ^{56}Fe, ^{57}Fe, ^{59}Co, ^{64}Zn, ^{66}Zn, ^{75}As, ^{107}Ag, ^{109}Ag, ^{110}Cd, ^{111}Cd, ^{112}Cd, ^{114}Cd and ^{115}Cd are the strongest contributor to the production of the excess heat, as illustrated in Figure 10a. The dashed horizontal lines of that figure

are drawn to indicate average rates of production nuclides necessary to generate heat at the level of 1 W and 10 W, as indicated.

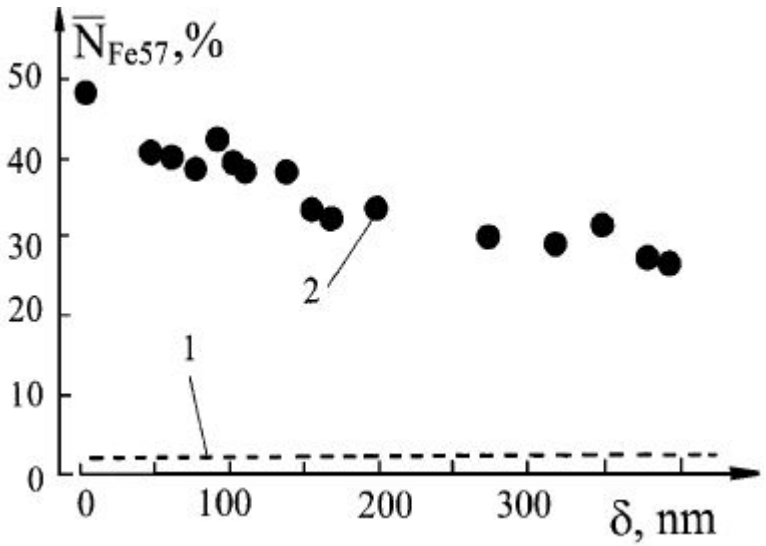

Figure 11: Dependence of the percentage of ^{57}Fe on the distance from the surface of the palladium cathode bombarded for four hours by deuterium ions (2000 volts and 100 mA).
****

5) Emission of soft X-rays.
As previously indicated, the plasma discharge was often associated with the emission of soft X-rays. They were studied with the a TLD and with the scintillation detector mounted on the photomultiplier. The intensity of X-rays was found to increase rapidly with the discharge current, as illustrated in Figure 12. The currents between 100 mA and 300 mA were obtained by changing the difference of potential from 800 V to 2000 V. The dependence of the X-rays intensity on the current is more or less the same for all cathode-gas combinations.

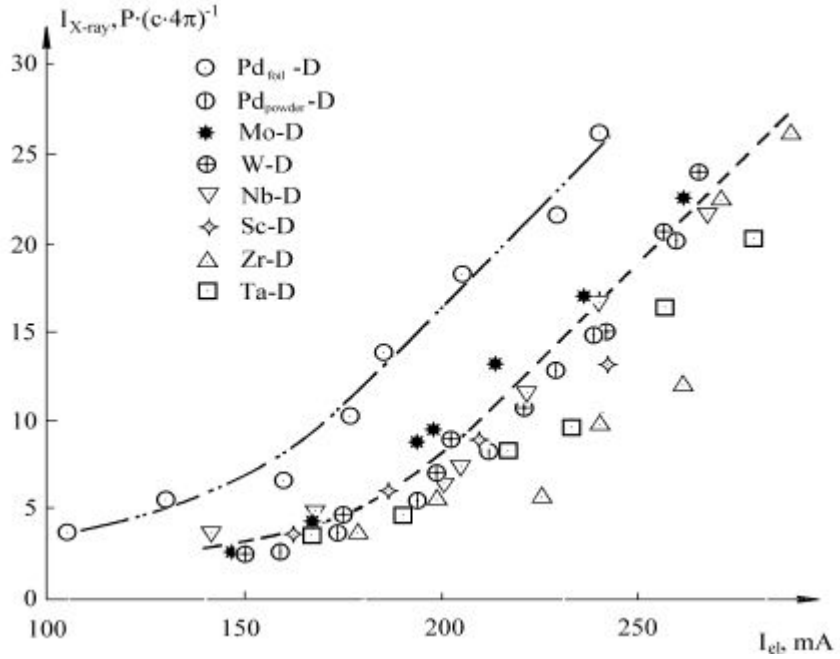

Figure 12: The dependence of the x-ray intensity, in roentgens per second per 4p, on discharge current for the palladium cathode in deuterium (open circles) and for other cathode-gas combinations (as indicated). The data were obtained using a calibrated scintillation detector. The discharge voltages ranged from 800 to 2000 V.
****

Bursts of X-ray emission were also observed several minutes to several hours after turning the current off. It was noticed that only prolonged exposures to plasma (at least 10 to 20 minutes) resulted in post-discharge bursts. Statistical analysis of the time distribution of bursts is consistent with the idea that excited levels, with energies between 1 keV and 2 keV, are populated inside the cathode during the ionic bombardment. The life times of these exited solid state levels, however, are presumably discrete (up to several msec).

6) Discussion:
The high-current glow discharge experiments, described above, revealed: 1) the existence of excess heat production, 2) progressive accumulation of small amounts of isotopes of several elements near the surface of the cathode, 3) emission of penetrating radiation and 4) emission of charged particles. These are manifestations of a previously unknown fundamental phenomenon. **It consists of the excitation of metastable states (energies 1-2 keV, lives tens of miliseconds) inside the crystaline material. These L,M states are presumably populated via inelastic interactions**

of plasma ions with the L,M electronic shells of the ions in the solid cathode. It is natural to postulate that nuclear reactions recorded in this study were initiated by formation of such states. Here is a general description of observed processes and products:

1) Under properly chosen conditions (pressure and distance between the electrodes), a region near the cathode becomes an ionic conductor. More than 90% of the applied potential difference, and more that 90% of the electric power, appears in that region. Positive ions are accelerated here up to energies between one and two keV.

2) The accelerated ions interact with the ions of the solid cathode material in several atomic layers near the surface. Such interactions are basically different from similar processes at higher energies (10 keV and above). The low energy processes can be described as:

$D^{+}* + Pd^{4+} \rightarrow Pd^{4+}* + D^{+}$

where Pd4+* is the positive palladium ion with the excited L, M electronic shells while Pd4+ is the ground state palladium ion in the crystal lattice of the cathode. The calorimetric measurements, and the evaluation of the maximum power of X-ray laser emission show that at least 20% of the power put into the discharge is used to populate the excited $Pd^{4+}*$ states, that is to initiate processes resulting in nuclear reactions.

3) The L, M excitation of ions near the solid body surface spreads into the depth of the material with the speed of an electromagnetic wave. Deexcitations (relaxations) and conversion processes take place inside the cathode.

4) It is reasonable to assume that the excited L,M levels are of a dipole oscillation nature. They deexcite along the two competing paths:

a) direct transitions to the ground state resulting in the emission of X-ray photons.

$Pd^{4+}* \rightarrow Pd^{4+} + \text{X-ray}$

b) transfer of energy to one of the electrons of the inner shell (K, L, M) resulting in the ejection of this electron. The created vacancy is filled by an electron from an outer shell and a photon of a characteristic X-ray is emitted.

$Pd^{4+}* \rightarrow Pd^{4+} + e^{-} + \text{X-ray}$

5) High current density is responsible for the high rate of populating of L,M levels and thus for the creation of an active layer with the inverted population. Fast relaxation of long-lived excited dipole-oscillation levels of ions results in X-ray. This is possible when the population density of L,M levels is sufficiently high due to a sufficiently large current density and when amplification is large. Under such conditions a laser beam burst can be generated through a single pass across the population inversion region (without mirrors).

6) Thus each current pulse results in the excitation of L,M levels of the solid material. The density of population is n v-d (cm-3) and the characteristic L,M temperature, TLM is 1-2 keV (more than 20,000,000 K). The characteristic times of these excited isomeric states, tLM, can exceed 10 ms. Among the nuclear reactions taking place in such an environment one can possibly consider:

$^{105}Pd \rightarrow [Pd]* \rightarrow {}^{48}Ca + {}^{57}Fe + 15.976\ MeV,$

splitting of the excited Pd into two transmutation products, or

$^{105}Pd + {}^{2}D \rightarrow [Pd;D]* \rightarrow {}^{107}Ag + 13.124\ MeV,$

formation of the excited silver nucleus followed by its deexcitation. Experimental data seem to indicate that the released

nuclear energy does not appear in the form of kinetic energies of splitting fragments.

7) The probability of such reactions, and the corresponding rate of excess heat, are determined by the difference between the actual value of (nLM*tLM) and some minimum value of this product. This is analogous to the well-known Lawson criterion used to evaluate the excess heat in thermonuclear reactions. Note that the population density, nLM, depends on the design of the cathode and on the parameters of discharge plasma. The characteristic time, tLM, on the other hand, depends on the intensity of X-ray emission. To maximize the excess heat the population density must be as high as possible while the emission of X-rays must be reduced to increase the tLM.

8) It is reasonable to think that the excitation of L,M levels is transmitted into the solid material in the form of transverse waves. For the flat cathode geometry (see Figure 1) the deexcitation of L,M levels is responsible for the decrease in population density (nLM) with the depth of penetration. The rate of transmutation reactions should consequently decrease with depth. Such expectation seems to be confirmed experimentally; the concentration of reaction products decreases with the depth. The situation, however, may be quite different for a cylindrical or spherical geometry. In such cases one may create conditions in which the density of population, nLM, increases with the depth leading to a possible explosion.

9) It is conceivable that a solid cathode whose metastable levels have very long lives can be used as a heat storage cell. The storage capacity of such a cell can be as high as 2108 Joule/cm3.

Do you remember the radio-talk file about CF that some of us downloaded after Larry Smith posted the address?

http://audio.kuer.org:8000/file/rw112702.mp3

One of the interviewed scientists was M. McKubre from SRI (Stanford Research Institute). I just finished reading the paper which he coauthored in 2000 and I am impressed. The paper can be downloaded as a pdf file from

http://lenr-canr.org/Features.htm

I admit that many details were not clear to me; the paper should be evaluated by electrochemists and material scientists. But the overall conclusions are very impressive. Palladium was loaded with deuterium by two methods: electrochemically and in a heated pressurized gas container. Control experiments were conducted using ordinary hydrogen. The previously reported anomalies (see below) were observed with deuterium but not with ordinary hydrogen.

1) Generation of heat (in excess of known sources).
2) Accumulation of ^{4}He (and some ^{3}He) atoms.
3) The isotopic ^{3}He/^{4}He ratio in accumulated products is orders of magnitude higher than in helium from air.
4) A nearly linear relation between the rates of excess heating and the rate of accumulation of ^{4}He.
5) The slope of the line shows that the amount of energy per atom is about 76% of what would be carried away by 23.8 MeV gamma rays in the hot d+d fusion.

Let me remind you that the absence of 23.8 MeV photons, in cold fusion, is a well established experimental fact. One of the authors, Peter Hagelstein from MIT, did write four papers (back in 1990?) on how energy can possibly appear in the form of crystal oscillations instead of photons. But no reference to these theoretical papers was made in his recent overview of the CF field at:

http://lenr-canr.org/index.htm

Referring to the 76% outcome the authors write: " Evidence for near-surface retention of ^{4}He in the lattice can be used to accommodate the discrepancy between measured and expected yields of ^{4}He." In other words, a sizable fraction of ^{4}He was presumably not squeezed out from the material in the process of analyzing it. Let me add that they used a mass spectrometer capable of distinguishing ^{4}He atoms from D_2 molecules.

My main question is why those who criticize CF usually refer to what happened in 1989 and not to recent work of

highly competent scientists? I suppose that many journals still consider CF to be pseudo-science and refuse publishing work done in that field. And that similar attitude exists among funding agencies. Is this a correct guess? I plan to attend the 10th International Conference of Cold Fusion next summer and find out. Information about the conference can be found at:

http://lenr-canr.org/Features.htm

By the way, in another paper the CF was referred to as the FP effect, to honor those who discovered it. Do you think that the field will be reevaluated for us, and for general public, by an appointed panel? They did it in 1989, why not now when so much more is known? Who should be expected to do this?

Let me also refer to the Technical ONR Report 1696, September 1995, coauthored by S. J. Szpak. The ONR stands for the Office of Naval Research. The report can be downloaded, as a very long pdf file, from

http://lenr-canr.org/Features.htm

In fact it is set of many documents that only chemists and material scientists will be able to comprehend completely. Browsing through this 146-pages file I made some notes, such as:

1) Back in 1991 ONR proposed a collaborative effort between NRAB, NWC and NRL (its research labs) to set up a coordinated CF experiment. The purpose was to investigate the anomalous effects associated with the prolonged charging of the Pd/D system. But this did not happen and each lab continued to investigate CF independently. The authors wrote: "In retrospect, imposing the condition of confirmation, rather than in-depth discussions, was unfortunate in view of what was known then and is known today, i.e. that the enormous complexity of the system and the unknown triggering mechanism make the reproducibility uncertain even if the procedure is followed rigorously."

2) Reproducibility became the focus of NRAB work. They invented the so-called "codeposition" process by which the FP effect (generation of excess heat) could be always observed. Instead of loading deuterium into preexisting Pd rods, they used an electrochemical process by which Palladium ions and D ions were simultaneously deposited in the form of a layer on a metal like copper or nickel.

3) They confirmed generation of tritium. The amount accumulated, together with generation of 2500 J of excess heat, turned out to be ten times higher than the background before.

4) Generation of soft x-rays was observed during the process.

5) Scanning electron micrographs of electrodes were made and correlated with other aspects.

6) X-ray crystallography was used during the FP process in a specially designed cell. The results were described in a report submitted on February 19, 1993.

7) The effect of current density on the rate at which heat was generated was investigated. Why should this kind of systematic work be called pseudo science? What does all this have in common with homeopathy or with N rays?

Scientific Breakthrough Liberates Energy Users from Fossil Fuel Dependence Technology breakthrough harnesses energy from the molecular structure of water.

BOISE, ID - Dec. 5, 2002 - Genesis World Energy, a privately funded consortium created by a group of military and space program research and development specialists, today unveiled a scientific breakthrough that allows consumers to easily access the energy contained within the hydrogen and oxygen molecular structure of ordinary water. This scientific breakthrough provides a limitless, low cost and environmentally clean source of energy that can be implemented with minimal cost and effort. The viability of using water as an energy source, previously a theoretical concept, is now a reality. "Water has always been the source of life on this planet, now it will also transform the way we create energy." said Charles Shaw, corporate counsel and spokesperson for Genesis World Energy. "The implications for worldwide energy generation and consumption are nothing less than staggering."

The Genesis Project

The technology is the result of nearly two years of continuous effort by a team of more than 400 visionaries from a wide spectrum of disciplines, including science, technology and engineering. Assembled as the "Genesis Project," the team discovered a way to extract far more energy from water than the extraction process itself required; differentiating this new fuel cell technology from any other development efforts thus far. The key component of the Genesis Project technology is the Genesis gCell, which through a series of electro-chemical processes separates hydrogen and oxygen molecules in water. The resulting gas molecules can either be burned cleanly as a replacement for natural gas or various other traditional forms of fuel, or may be remarried within Genesis eCells (an advanced fuel cell) to generate large amounts of electrical current. When both Genesis gCells and eCells are combined, the entire process becomes self-generating, recycling both water and electricity from the molecular reattachment phase. A more detailed description of the process can be found in the Genesis World Energy web site www.genesisworldenergy.org.

The Edison Device

The first application of this technology is represented in the "Edison Device," a self-contained, self-sustaining energy generation unit. Roughly the size of an outdoor air conditioning system, the power source can be quickly and easily installed in any home or business to provide virtually unlimited energy from any available water source. The Edison Device utilizes the existing electrical wiring and natural gas plumbing in a home or business to replace the energy provided by utility companies. The home version of the Edison Device produces approximately 30 kilowatts of combined gas and electrical energy per day. By comparison, the typical home uses between five to six kilowatts per day. The commercial model is capable of producing 100 kilowatts of energy per day. The energy generation portion of the devices has no moving parts. In fact, the only "mechanical" aspects of the equipment are small circulation pumps and micro-valves, making the Edison Device both silent and virtually

maintenance-free. A minimum amount of water is used over an estimated 20+ years of service life.

Market Ready

The commercialization of the devices is the responsibility of two business entities, Genesis World Energy and World Energy Management. Genesis World Energy is a technology development, production and supply consortium, while World Energy Management functions as the exclusive licensing representative for the worldwide distribution of Edison Devices.

According to Nejhla Shaw, World Energy Management President, "We will make Edison Devices rapidly available to governments and industries on a worldwide basis, with special licensing opportunities for those industries that will be most affected by the technology. For the first time in the history of the world, a clean and abundant source of renewable energy is as simple as the attachment of three wires, a gas line and a water hose."

BACKGROUND INFORMATION:

The Genesis Project

Creating an abundant, clean and renewable energy source from water

From The Source of Life, A New Source of Energy

Scientists and technologists have long explored viable sources of energy that would reduce the dependency of the world on fossil fuels and other non-renewable sources. Clean, low cost and abundant energy is, in many ways, the Holy Grail of the 21st Century. The economic, environmental and geopolitical implications of such a fuel source alternative are nothing less than staggering - and it is no exaggeration to say that these implications would extend to virtually every person on the planet.

One of the most promising energy technologies has been the generation of power using the earth's most abundant natural resource -- water. Just as water has been the source and sustainer of life on our planet, it also holds the key to transforming the way we generate energy. While generating energy from hydrogen and oxygen gases has been demonstrated in recent fuel cell technologies, none of these technologies have succeeded in creating a water-based energy source that can meet the demands of homes and businesses in a scientifically efficient and economically viable manner.

The Genesis Project

In September 2000 a privately owned and funded research and development organization with a half-century history of technology development for military and space programs decided to focus its resources on the barriers preventing the use of water as a total energy source. Assembling a team of more than 400 visionaries from a wide spectrum of disciplines, including science, technology and engineering, work groups were formed in a number of locations throughout the US. Code-named "The Genesis Project," these work groups engaged in a continuous research and development effort over an 18-month period. Only after the team's goals had been realized, were the details of what had been accomplished shared with everyone on the team. In June 2002, the goal of the Genesis Project was achieved: the creation of a low cost, self-sustaining process for generating unlimited energy from any available water source.

The Science Behind Genesis

Hydrogen and oxygen contained in water have always been the most attractive, yet elusive source of energy on the planet. Water molecules consisting of two parts hydrogen and one part oxygen are pure energy, yet the process of breaking water down into its molecular state consumed more energy than could be derived as a result. Genesis' breakthrough technology cracked the scientific secret to extracting far more energy from water than the extraction process itself required, making it possible to quickly and easily replace traditional forms of energy.

The gCell Process

The gCell is the fundamental component to the technology where three processes occur simultaneously. In the first of these processes, water is passed over catalytic reactants to produce an electrical voltage that excites the hydrogen and oxygen molecules. At the same time, a thermo, electro-catalytic reaction creates an effect similar to that of magnets with opposing polarities, separating the molecules into pure hydrogen and oxygen gases. In the third process, some of the hydrogen and oxygen molecules are reattached to generate additional electrical current that subsidizes the gas generation process - thus making the process self-sustaining. Since water is recovered and reused in the reattachment, gCells require only a few ounces of water per day. A single gCell stack, which is no bigger than a car battery, is capable of producing hundreds of cubic feet of customer usable gas per day. By comparison, the average American home in cold climate areas consumes approximately five cubic feet of gas per day.

The eCell Process

The eCell generates electricity and is one tool used in the conversion of hydrogen and oxygen contained in water into a consumer usable form of energy. The hydrogen and oxygen gases created in the gCells are used by eCells in a reverse reactant process that attracts the molecules much like magnets pulling themselves together. The resultant remarrying of the hydrogen and oxygen molecules produces, in a single eCell stack, more than 1,000 amps of electricity.

View the process here.

Bringing It All Together: The Edison Device

While the gCell and eCell technology is breathtaking in its simplicity, it needed to be incorporated into a mechanism that could viably meet residential and commercial energy requirements. This has been accomplished through the Edison Device: a self-contained energy generation system consisting of stacks of gCells and eCells. The Edison Device is roughly the size of a typical residential outdoor air conditioning unit.
Since the Edison Device utilizes the electrical wiring and natural gas plumbing in a home or business, installation is simple and quick. Three wires attach the Edison Device to existing electrical service connections, while the gas application requires connecting the Edison Device's gas feed line into the customer side of an existing natural gas line. Conversion of appliances from natural gas to hydrogen gas is accomplished by the use of inexpensive gas flow restrictors.

Market Ready

The Genesis Project has developed two market ready models of the Edison Device: a residential version and a commercial version. The residential model is capable of producing up to 30 total kilowatts of combined gas and electrical power per day (a typical home uses between five to six kilowatts), and the commercial model can generate up to 100 total kilowatts of energy. For heavier commercial requirements, multiple Edison Devices can be linked together.

The design of the Edison Device has proven that less is more. The energy-generating portion of the device has no moving parts - in fact, the only "mechanical" aspects of the Edison Device are the small circulation pumps and micro-valves that control the flow of water and gases. As a result, maintenance is limited to the occasional replacement of inexpensive water filters that can easily be accomplished by consumers themselves, while water usage is minimal over the device's projected 20+ years of service life!

The Ultimate Green Machine

Using only small amounts of water to meet residential and commercial energy requirements, producing no noise or emissions beyond the creation of ultra pure water, and utilizing an energy generation technology that is self-sustaining, the Edison Device is truly a "green machine." The Edison Device, and the underlying Genesis technology, represents a pivotal moment in human history: the promise of liberation from the shackles of fossil fuel dependency. The environmental impact alone is enormous. Limitless energy production without the consumption of fuels that deplete the ozone layer and pollute the planet. The reduction of drilling and mining for new energy sources. A more decentralized management and distribution of energy resources. Future applications will allow vehicles to operate on a pollution free basis.
And then, there are the economic considerations.

Rapid Deployment

The commercialization of the Edison Device is the responsibility of two recently created business entities: Genesis World Energy and World Energy Management. The first of these entities, Genesis World Energy, is a technology development, production and supply consortium. Its essential responsibility is to further the underlying Genesis Project technology and to establish and manage a roadmap for future product enhancements. The responsibility for the proliferation of the Edison Devices falls to World Energy Management, which is the exclusive licensing representative for the worldwide distribution of the Edison Device. This organization will make Edison Devices rapidly available to governments and industries on a worldwide basis through broad licensing agreements. These agreements will entitle licensees to assemble and distribute Edison Devices through the purchase of critical components from Genesis World Energy - allowing the technology originators to protect vital intellectual property.

Given the profound impact that the Genesis Project technology is likely to have on traditional producers and consumers of generated energy, World Energy Management will provide special licensing opportunities to those industries most affected by the introduction of the Edison Device. In the case of utility companies, for example, World Energy Management believes that the proliferation of Edison Devices will create a more stable and profitable business model. With the regulatory measures imposed on utility companies in the purchase and sale of energy, these companies would now have the option of charging the consumer a flat monthly rate for the rental of Edison Devices at a fraction of the cost of current power usage. While this would represent a smaller revenue stream, it would essentially be pure margin, since there would be no cost to the utility companies for the generated energy. Depreciation of the Edison Device equipment would also create a tax benefit. Consumers, for their part, would have the option of purchasing Edison Devices from other licensed manufacturers, thus forgoing monthly utility bills altogether.

An American Legacy

The scope and impact of the Genesis Project may be difficult to comprehend outside the context of a large and well-publicized government or industry initiative. Indeed, the efforts made by the Genesis Project to protect the anonymity of its members have, in part, been out of the desire to keep its technology firmly in the control of free market forces. Nevertheless, to view the Genesis Project as an unprecedented phenomenon is to ignore American history. Nearly a century ago, Thomas Edison brought together a small band of dedicated visionaries who, outside of any governmental agencies, taxpayer funded programs or corporate R&D structures, created technologies and products that transformed the world. The Edison Device is an heir to this uniquely American legacy of scientific inquiry, Yankee ingenuity, bold innovation and altruistic impulse.

17) Nuclear side of cold fusion

Ludwik Kowalski
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043.

Return to the clickable list of items

Let me summarize a paper of an Italian physicist T. Bressani "Nuclear Physics Aspects of Cold Fusion Experiments." It was presented at the Seventh International Conference on Cold Fusion in Canada (1998). The pdf file containing the article can be downloaded from < http://lenr-canr.org/Features.htm >

The author identifies **three questions** concerning cold fusion. They are:

1) How can Coulomb barrier be lowered between two deuterons to allow as many as about 10 to 20 fusion events per second (necessary to explain the actually measured excess heating rate.)

2) Why are branching ratios in cold fusion completely different from those in the free *(d + d)* fusion? Recall that the branch in which ^{4}He is produced is extremely rare in free fusion and that it is associated with the emission of 23.8 MeV gamma rays. The most common free fusion branches are: emission of neutrons plus ^{3}He, and emission of protons plus ^{3}T.

3) Do nuclear transmutation reactions take place in cold fusion, and why are their dominant byproducts stable rather than radioactive?

Before addressing the first issue the author refers to a study of Kasagi et al. in which palladium was bombarded with a beam of deuterium ions from an electrostatic accelerator. They found that the *(d+d)* cross section, measured down to 2.5 KeV, is 50 times larger when *d* is embedded in PdO than when in pure Pd or Ti! This experiment, writes Bressani, "is very important for at least two aspects. The first one, quite obvious, is that it is a dramatic proof of the **influence that condensed matter effects may have** on nuclear observables. The "Condensed Matter Nuclear Physics", whose first milestone is the Mössbauer Effect, may consider this experiment as the second milestone. The second aspect is that the enhancement of the cross section for *(d + d),* as measured following the method of Kasagi *et al.*, could be considered as one of the quality parameters needed in the choice of metals/compounds/alloys best suited to reach reproducible results in Cold Fusion Experiments."

The second issue, in my opinion, was not addressed, except by reviewing experimental results concerning light byproducts of cold fusion. These results confirm that dominant light byproducts are indeed very different from those resulting from free fusion. Experiments confirming the accumulation of 4He are described but the issue of 23.8 MeV gamma rays is not addressed.

Referring to **the third issue** the author writes: “I have always been absolutely skeptic about the possible existence of transmutations in Cold Fusion experiments. .....The experiment of Iwamura *et al.* 15 however is quite [promising]. Their cell, in which deuterium atoms are flowing through a Pd plate separating an electrolytic solution of D_2O/LiOD from a vacuum chamber, showed quite **strange phenomena**, like the production of Ti in quantities larger than the maximum contamination present in the samples and an isotope shift of the Fe atoms after the run.” I find this very interesting because the “isotope shift” **was also observed**, in a completely different setup, by Karabut et al.. I agree with the author that one should now be less skeptical about the reality of transmutation reactions.

It is probably too early to address the three basic questions formulated in this paper. We must first be certain that nuclear processes do take place in condensed matter without accelerated projectiles. On the other hand, blaming everything on “condensed matter” is not reasonable; nuclear reactions induced by accelerated projectiles nearly always occur in solid targets.

Look at the titles of these recent books; they are revealing.

1) C. Beaudette, "Excess Heat. Why Cold Fusion Research Prevailed." Concord, NH, 2000.
2) R.L. Park "Voodoo Science: The Road from Foolishness to Fraud," Oxford University Press, New York, 2000.

One reviewer wrote: “Professor Park does more than debunk, he crucifies... You'll never again waste time or your money on astrologers, quantum healers, homeopaths, spoon benders, perpetual motion merchants, or alien-abduction fantasists.”

But isn't "cold fusion" different from the above? I do not exclude the possibility that some "cold fusion" claims may have been fraudulent; con artists are naturally attracted to scientific controversies. But most of those who do research in the AE area ("anomalous energy" is a better term than "cold fusion') are likely to be honest. In fact, I suspect that Fleischmann and Pons might become Nobel laureates.

What makes the AE area different from voodoo science?

1) A large number (several hundred) of cooperating scientist in about 10 countries are actively involved.
2) Two Nobel laureates (Teller and Schwinger) were theorizing about AE at one time. Have they given up? I do not know.
3) Nearly all of the AE researchers have doctorates; many of them are (or were) associated with highly prestigious laboratories and universities. Many of them, including Fleischmann, are (or were) recognized leaders of disciplines.
4) These researchers organize one international conference each year and make results of their findings known to all who are interested.
5) Their methodology of validation is not different from that practiced by so-called "mainstream" scientists. They experiment, they hypothesize, they change their minds, they try to construct theories, they publish.
6) They are not secretive; they want to be heard and be criticized scientifically.
7) They want to have access (as authors) to all mainstream

journals in order to benefit from the peer-review process.
8) They want their proposals to be fairly evaluated by
NSF, DOE and other granting agencies.
9) They are highly unhappy about the "excommunication"
of the entire field caused by "heretical" mistakes made
by those who announced the discovery in 1989.

Is it not obvious that claims made by “astrologers, quantum healers, homeopaths, spoon benders, perpetual motion merchants, or alien-abduction fantasists” are completely different from those made by AE scientists?

Return to the clickable list of items

I am not a chemist and I cannot fully appreciate the article of G. Lonchampt et al. presented at the sixth International Conference on Cold Fusion in 1996. The three French authors were from "CEA - Centre d'Etudes Nucleaires" and "Ecole Nationale Superieure d'Electrochimie et d'Electrometallurgie" These institutions impress me; they are "impeccable." The title of the paper was: "Reproduction of Fleischmann and Pons experiments." It can be downloaded (in the pdf format) from:

http://lenr-canr.org/Features.htm

Here is the abstract: "The objective of this work is to check the reliability of the initial Fleischmann and Pons calorimeter for studying cold fusion from ambient to boiling temperature. After describing our experimental set up, the assessment of excess heat from the enthalpy balance is discussed. We have observed deposits on the electrodes after electrolysis, which, in our opinion, have a determining role in the excess heat generation. We show raw data from three runs. It is concluded that this calorimeter is well adapted for such cold fusion investigation. "

This paper is significant for two reasons. First, the original report of F&P, was often criticized for being incomplete. The calorimeter they used was considered inappropriate by some critics. And second, F&P were working in France at that time. In fact their assistance is recognized at the end of the article. It appears that what was missing in the original publication can be found in the French article together with many additional comments. I hope this information will be useful to electrochemists interested in methodology through which the original discovery was made. Let me finish this short item by quoting the conclusions.

"Our experience during this last three years, leads us to conclude that the Fleischmann and Pons calorimeter is very accurate and well adapted to study cold fusion phenomenon. It is simple and precise. However precautionary measures must be taken:
a) the Dewar must be of excellent quality, i.e. good vacuum, in order to
eliminate heat losses by conduction . . ..
b) temperature calibration of the thermistors must be done very precisely.
c) all electrical feedthroughs must be sealed off in order to eliminate
spilling off of electrolyte by capillarity.

Our results concerning the relative excess heat (percentage of excess heat to enthalpy input) can be summarized as follows:

a) below 70°C, between 0 and 5%
b) between 70°C and 99°C, about 10%
c) at boiling, up to 150% especially in the final phase which appears
as the best condition to get a large amount of excess heat.

As already done by S. Pons, with ICARUS 9, it is necessary to operate at boiling on a permanent basis to obtain the most significant results.

I downloaded several "cold fusion" publications from the

http://lenr-canr.com/Features.htm

web site. One of them, written in 2000 and authored by Scott R. Chubb from Research Systems Inc., is an excellent summary of social aspects of the "cold fusion conflict" as it evolved since 1989. I strongly recommend this article to educated non-scientists. This is an introduction to a compilation of seven articles published by those who were personally involved in cold fusion research. Was the compilation published? I do not know. A theoretically oriented physicist may be interested in another paper on "cold fusion," coauthored by Chubb; it can be downloaded from the above web site as (ChubbSRtheoretica.pdf).

Here are the sins for which "heretical cold fusion" was excommunicated when it was only seven months old:

1) Naming the phenomenon "cold fusion" without having any evidence for it.
2) Secrecy, presumably imposed by patent lawyers and administrators.
3) Saying that the method was "very simple to reproduce."
4) Suggesting that commercial harvesting was just behind the corner.
5) Announcing the discovery via a "press release."

The date of the "premature birth of CF" was March 23, 1989. Evidence for the (D+D --> He) fusion is now available, but that fusion, if it is fusion, does not resemble the so-called 'hot fusion" in plasma. In my opinion the essence of the ERAB report (November 1989) can be reduced to "it is not fusion we are familiar with, because of this and that." Importance of additional research was actually emphasized in the report. I agree with those who feel that the field is ready for another evaluation. The baby is now 13 years old! Will it live or will it be allowed to die?

21) On Reevaluation of AE Claims

Ludwik Kowalski (December 2002)
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

The decade of excommunication of the so-called “cold fusion” was not good for science and for its reputation. Why should anomalous energy (AE) be treated differently than any other area of interest? Nobody benefited from mutual accusations, such as “pathological science” or “pathological skepticism.” How can the scientific consensus about AE be reached? If I were an influential member of the Academy of Sciences I would call for the creation of two panels to reevaluate the entire field. One panel would consist of electrochemists and material scientists while the other would consist of experimental nuclear physicists. Each panel would have one well defined task, and a time limit, for example, two years, to accomplish it.

The chemists would be asked to answer one question: “is generation of excess heat real or not?” By definition, excess heat is thermal energy that can not possibly be due to chemical reactions. Physicists, on the other hand, would be asked a totally different question: “are chemically induced nuclear processes real or not?” Many claims have been made about the induced emission of 14 MeV alpha particles and of 3 MeV protons; this should not be difficult to either confirm or negate. The same applies to other processes, such as accumulation of tritium or big changes in the isotopic composition of some stable nuclides.

Confirmation of only one of these processes would be sufficient to validate a claim that a new phenomenon has been identified and that it should be studied. Non-confirmation, likewise, would be very significant. If the results reported by so many workers are not validated then the phenomenon of self-deception among hundreds of highly educated investigators would have to be examined. It would be an alert indicating a possibility that other areas of science might be in danger of being transformed into pseudoscientific “societies of mutual admiration.”

The modus operandus of the panels would be more or less similar to that established by ERAB, a panel created in 1989 to investigate the field of “cold fusion” two months after the excess heat discovery was announced. The members of the panel would travel to centers of AE research, observe experiments and be allowed to perform additional tests, if necessary. The burden of proof, naturally, would be on those who claim the phenomena to be real. The focus, at this early stage, would be on experimental facts and not on their practical or theoretical significance.

Selection of panel members would be made on the basis of qualifications. Every effort should be made to allow “cold fusion believers” to defend the claims, to repeat experiments, to use consultants, etc. But basic scientific methodology should be followed. Only recognized experts would be allowed to participate. Chemists, for example, would be asked to make sure that those who perform experiments, and those who critically evaluate them, have sufficient skill in electrochemistry, in metallurgy, in surface chemistry, in microanalysis, in spectroscopy, etc., according to what is being investigation. Without this neither negative nor positive conclusions can be trusted. Unfortunately, many self-appointed investigators of “cold fusion” in 1989 were amateurs whose conclusions were taken seriously.

The Academy of Sciences, acting on behalf of the entire scientific community, would agree in advance that the field of AE should be rehabilitated if at least one claim were validated. Failure to validate a single claim, on the other hand, would show that the field has not yet matured to the level of science. To rehabilitate means to deliver a general apology, in the name of mainstream science, for unfair treatments which occurred in the past. The purpose would be to make clear that research proposals in the area of AE are as desirable as in any other area of science. Naturally, I would not object if the reevaluation of the AE field were sponsored by another organizations, such as NSF, DOE, ACS or APS.

The reunification of AE with mainstream science, if it occurs, should not mean that every claim made under the banner of "cold fusion" is automatically validated. It should only mean that all claims should have an equal right to be

examined. The reunification would strengthen, rather than weaken, science and its respect in societies. Who is against it?

22) Excess Heat and Helium Again

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J. 07043

Return to the clickable list of items

To appreciate experimental difficulties associated with AE (anomalous energy) electrochemical experiments, one may be advised to read the paper of B. Bush and J. Lagowski. The paper was presented at the 7th International Conference on Cold Fusion (1998). It can be downloaded from:

http://lenr-canr.com/Features.htm

The paper describes two stages of a typical experiment. First is the preparatory loading stage (introducing a sufficient amount of D ions into the crystal structure of Pd), second is the excess heat generation stage. The loading may take several days and it is performed at law current densities, such as 1 mA/cm^2. To switch to the second mode the current density must be increased to about 20 mA/cm^2. This often, but not always, leads to generation of excess heat for as long as the cathode remains loaded. Some cathodes last much longer than others. It depends on the origin of palladium and on its surface was prepared.

The authors write: “Many laboratories have reported generating excess heat during deuterium oxide electrolysis at palladium cathodes, many of these reports being extremely convincing. The major difficulty with the topic of excess heat generation is not reproducibility, but rather control. The ability to control the circumstances of the electrolysis so that the excess heat can be ‘turned on, and turned up or down’ has eluded us as yet.” Let me add that, according to more recent reports, the reproducibility is now much higher than it used to be. Microscopic examinations of surfaces often helps to reject potentially unproductive cathodes.

A section on calorimetry is also instructive; it warns that some kinds of calorimeters are more suitable than others. The authors write: “thermal flux calorimeters based on Peltier devices (e.g. Melcor refrigichips) will fail in the most insidious fashion possible , several man years have been wasted on Peltier devices between the Navy and ourselves. We prefer to operate with the calorimeters submerged in a water bath, because this provides for reliable long term temperature stability. Further, because we are concerned with the helium produced by the excess heat generating reaction, we find it particularly useful to submerge the calorimeters in water, because helium is less soluble in water than in air and we can sparge the helium out of the water by bubbling liquid nitrogen boil-off gas through the enclosed water continuously to keep atmospheric contamination out.”

The section of the paper dealing with generation of helium is indeed very interesting. The authors write: “We entered this field by performing helium analysis as a nuclear products analysis. Our first effort was qualitative: 8 times during the generation of excess heat, helium was detectable in the electrolysis off-gas; 6 times when no excess heat was being generated, no helium was detectable in the electrolysis off-gas. This qualitative finding showed that the Pons and Fleischmann effect is a nuclear process occurring at the surface of the cathode. Subsequent quantitative helium versus energy analysis performed by ourselves,[2] and Dr. M. H. Miles working independently indicated that the excess heat and helium was produced via the D + D --> ^4He + 23.82 MeV(heat) reaction pathway.” I was particularly impressed by a demonstration that the observed $^4He/^3He$ ratio was found to be significantly different from that of helium in air. This

rules out a possibility that the progressive accumulation of He can be attributed to atmospheric contamination.

23) Palladium Powder

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J. 07043

Return to the clickable list of items

Another paper worth reading is that of Arata and Zhang; it can be downloaded from:
<P>
http://lenr-canr.com/Features.htm
<P>
Recognizing that surface atomic structure plays a key role in the production of AE (anomalous energy) and that lattice imperfections (such as lattice defects, amorphous structures, intense local stress and micro cracks) are very important the authors decided to use a bottle-like palladium cathode filled Pd-black powder. The electrochemical process was used to supply deuterium to the bottle. Deuterium entered the "bottle" through its thin walls and interacted with powder particles. In the abstract of their article (Jpn. Acad., Ser. B, 1994. 70 ser. B: p. 106.) the authors wrote:

"Using this cathode, the authors confirmed the sustained production of a significantly abnormal amount of energy over a period of several months that could not be ascribed to chemical reaction energy. The chemical reaction energy of 0.1 [mol] Pd-black used is only 4[kJ], but more than 200[MJ] of excess energy was continuously produced for over 3000 [hr] at an average rate of 50-100 [kJ/hr] using a DS-cathode with a same quantity of Pd-black. Intermittent operation over a period of two years using this structure proved the complete reproducibility of these results."

I know of one person who is now trying to get excess heat from Pd-black in a totally different way. He is a recognized leader of great US projects and is highly qualified for that kind of study. The outcome is likely to be described at the 10th International Cold Fusion Conference this summer. I plan to attend the conference and will share what I learn there.

24) Three Tutorials

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J. 07043

Return to the clickable list of items

****
What follows are three introductory lessons on what used to be called cold fusion, plus one slightly more advanced lesson on the same topic. The authors are top scientists. The first is a professor from MIT, the other two are from the US government research laboratories. All three are of AE (anomalous energy) veterans from the year one. What follows are three introductory lessons on what used to be called cold fusion, plus one slightly more advanced lesson on the same topic. The authors are top scientists. I think that AE is a better term than “cold fusion” but some refer to it as LENR (low energy nuclear reactions) and CANR (chemically activated nuclear reactions). For more information go to < http://lenr-anr.org/index.html >
****

It Started in 1989 . . .

by Peter Hagelstein

Many of us recall the controversy surrounding the announcement of claims of observations of fusion reactions in a test tube that were made in 1989. At the time, these claims were greeted with considerable skepticism on the part of the physics community and the scientific community in general.

The principal claim of Pons and Fleischmann

The principal claim of Pons and Fleischmann in 1989 was that power was produced in palladium cathodes that were loaded electrochemically in a heavy water electrolyte. The evidence in support of this was a measured increase in the temperature in the electrochemical cell. There was no obvious evidence for nuclear reaction products commensurate with the claimed heat production. Fleischmann speculated that perhaps two deuterons were somehow fusing to He-4 through some kind of new mechanism.

Rejection by the physics community

This claim was not accepted by the physics community on theoretical grounds for several reasons: First, there was no mechanism known by which two deuterons might approach one another close enough to fuse, since the Coulomb barrier prevents them from approaching at room temperature.

Second, if they did approach close enough to fuse, one would expect the conventional dd-fusion reaction products to be observed, since these happen very fast. Essentially, once two deuterons get close enough to touch, reactions occur with near unity probability, and the reaction products (p+t and n+He-3) leave immediately at high relative velocity consistent with the reaction energy released. To account for Fleischmann's claim, the proposed new reaction would seemingly somehow have to make He-4 quietly and cleanly, without any of the conventional reaction products showing up, and would somehow have to arrange for this to happen a billion times faster than the conventional reaction pathway. Most physicists bet against the existence of such a magical new effect.

Third, the normal pathway by which two deuterons fuse to make He-4 normally occurs with the emission of a gamma ray near 24 MeV. There was no evidence for the presence of any such high energy gamma emission from the sample,

hence no reason to believe that any helium had been made. Finally, if one rejects the possibility that any new mechanisms might be operative, then the claim that power was being produced by fusion must be supported by the detection of a commensurate amount of fusion reaction products. Pons and Fleischmann found no significant reaction products, which, given the rejection of new mechanisms, implied an absence of fusion reactions.

An alternate explanation is proposed

The physicists decided in 1989 that the most likely reason that Pons and Fleischmann observed a temperature increase was that they had made an error of some sort in their measurements. When many groups tried to observe the effect and failed, this led most of the physics community to conclude that there was nothing to it whatsoever other than some bad experiments.

The claim of Jones

A second very different claim was made at the same time in 1989 by Steve Jones. This work also involved electrochemistry in heavy water and the observation of reaction products corresponding to the conventional dd-fusion reactions. The initial publication showed a spectrum of neutron emission that Jones had detected from a titanium deuteride cathode loaded electrochemically. The response of the physics community was skeptical, as the signal to noise ratio was not particularly impressive. Given the polarization of the physics community in opposition to the claims of Pons and Fleischmann (which were announced essentially simultaneously), the physicists were not of a mood to accept much of any claims that fusion could happen in an electrochemical experiment at all. Jones went to great lengths to assure fellow scientists that his effect was completely unrelated to the claims of Pons and Fleischmann, and was much more reasonable.

Also rejected

Physicists had reason to be skeptical. Theoretical considerations indicated that the screening effects that Jones was relying on were not expected to be as strong as needed to account for the fusion rates claimed. As this experiment could not seem to be replicated by others at the time, it was easy for the physics community to reject this claim as well.

Cold fusion, weighed and rejected with prejudice

Cold fusion, as the two different claims were termed, was dismissed with prejudice in 1989. The initial claims were made near the end of March in Utah, and the public refutation of the claims was made at the beginning of May. It only took about 40 days for the physics community to consider the new claims, test them experimentally, and then announce loudly to the world that they had been carefully weighed and rejected.

Following this rejection, physicists have treated cold fusion rather badly. For example, Professor John Huizenga of Rochester University was selected to be co-chair of the DOE ERAB committee that met to review cold fusion and issue a report. Shortly afterward, he wrote a book entitled Cold Fusion, The Scientific Fiasco of the Century, in which he discusses the claims, the experiments, and the extreme skepticism with which the new claims were greeted. Robert Park discusses the subject in his book entitled Voodoo Science. You can find many places where physicists and other scientists happily place the cold fusion claims together with claims of UFOs and psychic phenomena.

COLD FUSION: What is it and what does it mean to science and society?

by Edmund Storms

Cold fusion is important because it promises to be a new source of pollution-free, inexhaustible energy. In addition, it is important because it reveals the existence of a new way nuclei can interact that conventional scientific theory predicts is

impossible. What then is this phenomenon that suffers such promise and rejection?

Energy can be obtained from the nucleus in two different ways. On the one hand, a large nucleus can be broken into smaller pieces, such as is experienced by uranium in a conventional nuclear reactor and by the material in an atom bomb. This is called fission. On the other hand, two very small nuclei can be joined together, such as occurs during fusion of deuterium and tritium in a Hot Fusion reactor and in a hydrogen bomb. This process, called fusion, also takes place in stars to produce much of the light we see.

The fission reaction is caused to happen by adding neutrons to the nucleus of uranium or plutonium to make it unstable. The unstable nucleus splits into two nearly equal pieces, thereby releasing more neutrons, which continue the process. As every one now knows, this process produces considerable waste that is highly radioactive. The uranium used as fuel also occurs in limited amounts in the earth's crust. As a result, this source of energy is not ideal, although widely used at the present time.

The normal hot fusion reaction requires two deuterium or tritium nuclei to be smashed together with great energy. This is accomplished by raising their temperature. However, this temperature is so high that the reactants cannot be held in a solid container, but must be retained by a magnetic field. This process has proven to be very difficult to accomplish for a time sufficient to generate useable energy. In spite of this difficulty, attempts have been under way for the last 40 years and with the expenditure of many billions of dollars. Success continues to be elusive while the effort continues.

Cold fusion, on the other hand, attempts to cause the same process, but by using solid materials as the container held at normal temperatures. The container consists of various metals, including palladium, with which the deuterium is reacted to form a chemical compound. While in this environment, the barrier between the deuterium nuclei is reduced so that two nuclei can fuse without having to be forced together. Because the process causing this to happen is not well understood, the possibility is rejected by many conventional scientists. Difficulty in producing the process on command has intensified the rejection. While this difficulty is real, it has not, as many skeptics have claimed, prevented the process from being reproduced hundreds of times in laboratories all over the world for the past 13 years. As you will see by reading the reviews and papers in our library, the process continues to be reproduced with increasing ease using a variety of methods and materials.

What is the nature of this process and why has it been so hard to understand? To answer this question, a person needs to understand the nature of the barrier that exists between all nuclei. Because all nuclei have a positive charge in proportion to their atomic number, all nuclei repeal each other. It is only the surrounding electrons that hold normal matter together, with the nuclei being at considerable distance from each other, at least on the scale of an atom. When attempts are made to push the nuclei closer, the required energy increases as the nuclei approach one another. However, when deuterium dissolves in a metal, it experiences several unique conditions. The surrounding metal atoms produce a regular array that is able to support waves of various kinds. These waves can be based on vibration of the atoms (phonons), vibration of the electrons, standing waves of electromagnetic energy, or a wave resulting from conversion of the deuterium nuclei to a wave. In addition, the high density of electrons can neutralize some of the positive charge on the deuterium nuclei allowing a process called tunneling, i.e.. allowing passage through the barrier rather than over it. The mechanism of this neutralization process is proposed to involve a novel coherent wave structure that can occur between electrons under certain conditions. All of these wave processes have been observed in the past under various conventional conditions, but applying them to the cold fusion phenomenon has been a subject of debate and general rejection.

While the debate based on wave action has been underway, people have proposed other mechanisms. These include the presence of neutrons within the lattice. Normally, neutrons are unstable outside of the nucleus, decomposing into a proton, an electron, and a neutrino. Presumably, this reaction can be reversed so that neutrons might be created in a lattice containing many free electrons and protons. Having no charge, the neutron could then interact with various atoms in the lattice to produce energy. These neutrons might also be hidden in the lattice by being attached to other nuclei in a stabilized form, to be released when conditions were right. Several particles normally not detected in nature also have been proposed to trigger fusion and other nuclear reactions.

While search for a suitable mechanism has been underway, an understanding of the environment that triggers the mechanism has been sought, the so-called nuclear-active-environment. Initially, this environment was thought to exist in the bulk of the palladium cathode used in the Pons-Fleischmann method to produce cold fusion. It is now agreed that the nuclear reactions only occur in the surface region. Recent arguments suggest that this surface layer does not even require palladium for it to be nuclear-active. Nuclear reactions have now been produced in a variety of materials using many methods. The only common feature found in all of these methods is the presence of nano-sized particles of material on the active surface. If this observation is correct, four conditions seem required to produce the nuclear reactions. First, the particle must have a critical small size; second, it must contain a critical concentration of deuterium or hydrogen; third, it must be constructed of certain atoms; and fourth, it must be exposed to a source of energy. This energy can take the form of a sufficiently high temperature, a significant high flux of hydrogen through the particle, application of energetic electrons or charged particles, or application of laser light of the proper frequency. Until, the importance of these factors is understood, the effect will continue to be difficult to replicate.

A Science Tutorial

By Talbot Chubb

First it is important to recognize that there are four distinct types of energy production:

1) chemical energy, that powers our cars and most of our civilization
2) nuclear fission energy, as used to generate about 15% or our electricity
3) hot fusion nuclear energy, which powers the sun and most stars
4) cold fusion nuclear energy, which appears as unexplained heat in a few experimenter's laboratory studies and which most scientists believe is impossible.

The three types of nuclear energy produce 10 million times as much heat per pound of fuel than occurs with chemical energy. How do these types of energy differ? To understand this question you need to know some chemistry and physics.

Lesson 1
Nature has provided us with two types of stable charged particles, the proton and the electron. The proton is heavy, normally tiny, and has a positive charge. The electron is light, normally large and fuzzy, and has a negative charge. The positive charge and the negative charge attract each other, just like the north pole of a magnet attracts the south pole of a magnet. When you bring two magnets together with the north pole of one facing the south pole of the other, they pull together, bang! When they bang into each other they release a little bit of energy in the form of heat, but it is too small an amount to easily measure.

To pull the magnets apart you have to do work, which is another way of saying you have to use up energy. It's almost like pulling a rock back up a hill. Rolling the rock down a hill actually creates a little heat, and pulling the rock back up the hill takes energy. In the same way the positive charge of the proton pulls on the negative charge of the electron and they stick together releasing energy in the process. The result is a hydrogen atom, designated H. A hydrogen atom is nothing but a fuzzy electron hugging a compact proton. The proton is the nucleus of the hydrogen atom. If you knock the electron off the hydrogen atom you get a positive ion H^+, which is nothing more than the original proton. An ion is the name applied to an atom or molecule that has lost or gained one or more electrons, hence is no longer electrically neutral.

Lesson 2
As you know, nature has provided us with more than one type of atom. We have oxygen atoms, nitrogen atoms, iron atoms, helium atoms, etc.. How do these atoms differ? The answer is that they all have different types of nuclei (plural of nucleus, from the Latin). And these different nuclei all have different numbers of protons inside them, which means they all have different plus charges.

The nucleus of the helium atom has 2 protons inside it, hence has plus 2 charge, and requires 2 electrons to neutralize its charge. When 2 electrons stick to it, it becomes a helium atom. The oxygen nucleus has 8 protons and has charge 8. When 8 electrons stick to it, it becomes an oxygen atom. The nitrogen atom has 7 electrons, and the iron atoms something like 26. But all the atoms are built more or less the same way, with a compact positively charged nucleus embedded in a cloud of fuzzy electrons. The difference in size between the compact nucleus and the fuzzy electrons is enormous. The sun has a diameter only about 100 times that of the earth. The electron cloud on an atom has a diameter which is about 100,000 times that of the nucleus. Cube these numbers to get the difference in volumes.

Lesson 3

We now are in a position to understand what chemical energy is. The atoms, all electrically neutral, can actually join with each other and release more energy. This is another way of saying that they can join into more stable configurations. The electrons in an atom try to configure themselves so as to get as close as possible to their nucleus, but their fuzzy nature requires that they take up a certain volume of space. However, if they join together with the electrons of another atom they can usually find a tighter configuration that leaves them closer to their beloved nuclei. For example, 2 hydrogen atoms can join together into a more compact configuration if each hydrogen atom contributes its electron to a 2-electron cloud, which the separate protons share. In this manner they form a grouping of the 2 electrons in a single cloud, together with the 2 isolated protons spaced apart from each other but still within the electron cloud.

The result is a heat-producing chemical reaction H + H => H_2. (The => means "goes to" or "becomes".) The H_2 configuration is the hydrogen molecule, and when you buy a tank of hydrogen gas, H_2 molecules is what you get. Furthermore, the 2 electrons of the H_2 molecule and the 8 electrons of the O atom can find a still more compact configuration by combining their electrons to create the water molecule H_2O, plus heat. The water molecule is really a single cloud of electrons in which are embedded the three point-like nuclei to form a minimum energy configuration. So when we burn oil or coal we reconfigure the electrons to produce more stable configurations of point-like nuclei embedded in electron clouds, liberating heat. So much for chemical energy.

Lesson 4

We have slid over one point in the above discussion. How does Nature make a nucleus containing two or more protons in the first place. After all, each of the protons has a positive charge, and the positive charges repel each other very strongly when they are separated by a tiny distance, equal to the distance across a nucleus. The repulsion of like charges is just like the repulsion between the north poles of two magnets when they are pushed together the wrong way. Something must overcome this repulsion, or else the only kind of atoms we would have would be those of hydrogen. Fortunately, this is not what we observe. The answer is that there is a second kind of force which acts on protons. This is the nuclear force. The nuclear force is very strong but requires particles to almost sit on each other to have any effect.

Also, there is a second kind of heavy particle, which is just like a proton, except that it has no positive or negative charge. It is not pushed away by the proton's plus charge. This other kind of particle is called the neutron, since it is electrically neutral. A peculiar fact of life is that it exists in stable form only inside a nucleus. When not in the nucleus it changes into a proton, an electron and a very light anti-neutrino in about 10 minutes. But it lasts forever inside a nucleus. Anyway, the neutron and the proton very strongly attract each other once they get close enough together, and then they combine to form a highly stable pair called a deuteron, which we designate D^+. The single deuteron, when it combines with a single electron, forms the heavy hydrogen atom called deuterium, designated D.

A second nuclear reaction occurs when two deuterons make contact. When they can be forced together so as to make contact, the 2 deuterons fuse, making a doubly charged particle. The grouping of 2 protons and 2 neutrons is even tighter than the proton-neutron grouping in the deuteron. The new particle, when neutralized by 2 electrons, is the nucleus of the helium atom, designated He. Larger groupings of neutrons and protons exist in nature and serve as the nuclei of carbon, nitrogen, oxygen, and iron, etc. atoms. All of these groupings are made possible by the very strong nuclear force, which is felt between particles only when they are in contact or share the same nucleus-size volume of space.

Lesson 5

We can now understand normal nuclear energy, which is really nuclear fission energy. During the early history of the

universe massive stars were formed. In the explosion of these massive stars, lots of different types of nuclei were formed and exploded back into space. Second and later generation stars and planets were formed from this mix, including the sun. In the explosion process probably every possible stable configuration of protons and neutrons was produced, plus some almost-stable groupings, such as the nucleus of the uranium atom. There are actually 3 different types of uranium atom nuclei, called uranium-234, uranium-235, and uranium-238. These "isotopes" differ in their number of neutrons, but they all have 92 protons.

The nuclei of all uranium atoms can go to a lower energy configuration by ejecting a helium nucleus, but this process occurs so rarely that the Earth's uranium has already lasted over 4 billion years. But the uranium nuclei are unstable in another way. In general, groupings of protons and neutrons are happiest if they have about 60 protons-plus-neutrons. The uranium nuclei contain more than three times this number. So they would like to split in two, which would release a lot of heat. But nature doesn't provide a way for them to split apart. They have to first go to a higher energy configuration before splitting in two. However, one of the three forms of uranium nucleus found in nature called uranium-235 and designated ^{235}U, gains the needed energy if it captures a neutron. The energized nucleus that results from neutron capture then splits apart with the release of an enormous amount of energy, and incidentally with release of additional neutrons. The additional neutrons can then split more uranium-235 nuclei, keeping the reaction going. This is what happens in nuclear power plants, where the heat, which is the end product of the nuclear splitting process, is used to boil water, generate steam, and turn electrical generators. (One also gets lots of radioactive products, which are a nuisance to dispose of safely.)

Lesson 6

We are now also in a position to understand hot fusion nuclear energy. As mentioned in lesson 5, the groupings of protons plus neutrons is most stable when the numbers of neutrons and protons approximate those found in the nucleus of an iron atom. Just as uranium has too many neutrons plus protons to be comfortable, so the light elements like hydrogen, helium, carbon, nitrogen and oxygen have too few. If the nuclei can be made to make contact under proper conditions, they can combine to create more stable groupings, plus heat. This is the process of fusion. Nature has found a way of doing this in stars like the sun. All Nature has to do is heat compressed hydrogen hot enough and wait long enough and hot fusion will occur.

If Nature were to start with deuterium, which already has a paired proton and neutron, the task would be relatively easy in a star. Temperature is a measure of how much speed an atom of a given type has as it bangs around inside a cloud of such atoms. The higher the temperature, the higher the speed and the closer the atoms get to each other momentarily during a collision. In a star the temperatures are high enough that all the electrons quickly get knocked off the atoms, so one is really dealing with a mixed cloud of electrons and nuclei. At very high temperature the nuclei occasionally get close enough during collisions for the pulling-together short range nuclear force to turn on. Then the nuclei can stick together and go to a lower energy grouping of protons plus neutrons, releasing heat.

Hot fusion nuclear energy is an attempt do carry out this process in the lab, using deuterium and mass-3 hydrogen (whose nucleus is a compact grouping of 1 proton and 2 neutrons) as the gas. Hot fusion requires that the gas be contained at temperatures of hundreds of millions of degrees, which can be done with the help of magnetic fields, but only for 1 or 2 seconds. The hope is to contain the gas for longer times. During the period of high temperature containment nuclear reactions occur during collisions. The main form of energy release is ejection of high energy neutrons and protons. The proton energy quickly converts to heat. The neutron energy can also be converted to heat but makes the equipment highly radioactive. It then becomes difficult to repair the equipment, which could make hot fusion a poor candidate for commercial power production. In any case hot fusion power is a dream that is still probably at least 50 years away. But most scientists view hot fusion as the only way to achieve fusion power. Hot fusion produces less radioactivity than fission power, is environmentally benign, and has a virtually limitless fuel supply on earth. (many millions of years at present energy usage rates).

Lesson 7

So now we come to cold fusion. Cold fusion may provide an easier and non-radioactive way of releasing nuclear fusion energy. Cold fusion relies on a different way of letting the protons and neutrons in one nucleus make contact with those in another nucleus, so that the nuclear force can bring them into a more stable configuration. The requirement for any

nuclear reaction to occur is that the reacting nuclei occupy the same volume of space. This condition is called particle overlap. In hot fusion particle overlap is brought about briefly by banging the nuclei together so as to overcome momentarily the repulsion of the two positive charges which try to keep the particles apart. In cold fusion particle overlap conditions are achieved by making deuterium nuclei act as fuzzy objects like electrons in atoms, instead of like tiny points.

When either light or heavy hydrogen is added to a heavy metal, each hydrogen "atom" occupies a position inside the metal where it is surrounded by heavy metal atoms. This form of hydrogen is called interstitial hydrogen. With interstitial hydrogen the electrons of the hydrogen atom become part of the pool of electrons of the metal. Each hydrogen nucleus oscillates back and forth through a negatively charged electron cloud provided by the electrons of the metal. They can be thought of as moving back and forth like the pendulum in a grandfather clock. This vibration exists even at very low temperature, due to a peculiarity of a branch of physics called quantum mechanics. The vibration is called zero point motion. The nucleus then becomes a fuzzy object, like the electrons in an atom. But this amount of fuzziness is not enough to permit a hydrogen nucleus to make contact with another hydrogen nucleus. To get two or more hydrogen nuclei to share the same volume one most go one step further. In a metal electrical current is carried by electrons that act more like vibrating matter waves than like point particles. If electrons did not become wave-like inside solids, there would be no transistors and no present day computers. This wave-like kind of electron is called a Bloch function electron.

The secret of cold fusion is that one needs Bloch function deuterons. One needs wave-like deuterons inside or on the surface of a solid in order that two or more deuterons share the same volume of space. But once the Bloch function deuterons are created, the nuclear force comes into play and the protons and neutrons making up the deuterons can rearrange themselves into the more nuclearly stable Bloch function helium configuration, with release of heat. To study cold fusion the experimenter has to force deuterons to assume the wave-like form and keep them in the wave-like state. Cold fusion experiments demonstrating release of excess heat show that this can be done. But at present no one knows how to do it reliably. Since cold fusion promises millions of years of energy without the problems of global warming or radioactivity, a real effort should be made to learn how.

Technical Introduction to LENR-CANR

by Edmund Storms

At low energies, the Coulomb barrier prevents nuclei from coming together and fusing to form a single nucleus. To initiate a nuclear reaction, several methods are used. Nuclear reactions are normally initiated by pushing two atoms together with enough force to overcome the Coulomb barrier by brute force, or by using neutrons which penetrate the nuclei without seeing a barrier. (Neutrons have no electrical charge, so the Coulomb barrier does not stop them.) These forces are normally provided by a high-temperature plasma or by accelerating ions to high energies. In contrast, LENR describes the mechanism and conditions that cause a variety of nuclear reactions to take place with a relatively low activation energy. These unique conditions reduce the need for excessive energy. The normal method forces the nuclei together, while the new method encourages them to come together. The challenge has been to understand the unique characteristics of the necessary solid structure such that this structure could be generated at will.

Because the proposed method is unique, at odds with current nuclear theory, and is still difficult to reproduce, support for studies in many countries, but not all, has been very limited. Nevertheless, considerable information has accumulated over the last 13 years since Profs. Stanley Pons and Martin Fleischmann showed the world the possibilities inherent in this phenomenon. Much understanding is buried in conference proceedings and reports that are not available to a serious student. This information will, as time permits, be made available on this site. Students of the subject are also encouraged to use this site to interact with other people in the field and provide objective critiques of the work published here.

PHENOMENA DISCUSSED IN SOME OF THE PAPERS

At least 10 ways have been demonstrated to produce anomalous heat and/or anomalous elemental synthesis. A few of these methods will be described here. For course, not all of the claims are worthy of belief nor are they accepted by many people. Nevertheless, the claims will be described without qualifications in order to provide the reader with the latest understanding.

The most studied method involves the use of an electrolytic cell containing a LiOD electrolyte and a palladium cathode. Current passing through such a cell generates D^+ ions at the cathode, with a very high effective pressure. These ions enter the palladium and, if all conditions are correct, join in a fusion reaction that produces He-4. Initially palladium wire and plate were used, but these were found to form micro cracks, which allowed the required high concentration of deuterium to escape. Later work shows that the actual nuclear reaction occurs on the surface within a very thin layer of deposited impurities. Therefore, control of this impurity layer is very important, but rather difficult. The use of

palladium is also not important because gold and platinum appear to be better metals on which to deposit the impurity layer. This method is found, on rare occasions, to generate tritium within the electrolyte and transmutation products on the cathode surface. Different nuclear reactions are seen when light water (H_2O) is used instead of D_2O, although the amount of anomalous energy is less when H_2O is used. These observations have been duplicated hundreds of times in dozens of laboratories, as described in several of the review articles available on this website.

Application of deuterium gas to finely divided palladium, and perhaps other metals, has been found to generate anomalous energy along with helium-4. Both palladium-black as well as palladium deposited as nanocrystals on carbon have shown similar anomalous behavior. In both cases. the material must be suitably purified. Palladium deposited on carbon can and must be heated to above 200/260°C for the effect to be seen. When deuterium is caused to diffuse through a palladium membrane on which is deposited a thin layer of various compounds, isotopes that were not previously present are generated with isotopic ratios unlike those occurring naturally.

A plasma discharge under H_2O or D_2O between various materials generates many elements that were not previously present. When the electrodes are carbon and the plasma is formed in H_2O, the main anomalous element is iron. This experiment is relatively easy to duplicate.

Several complex oxides, including several superconductors, can dissolve D_2 when heated. When a potential is applied across a sheet of such material, the D^+ ions are caused to move and anomalous heat is generated.

If deuterium ions, having a modest energy, are caused to bombard various metals, tritium as well as other elements not previously present are generated. These ions can be generated in a pulsed plasma or as a beam.

When water, either light or heavy, is subjected to intense acoustic waves, collapse of the generated bubbles on the surrounding solid walls can generate nuclear reactions. This process is different from the fusion reaction claimed to occur within a bubble just before it disappears within the liquid because neutrons are not produced in the former case, but are produced in the latter case. This method has been applied to various metals in heavy water using an acoustic transducer and in light water using a rotating vane which generates similar acoustic waves.

HOW TO EXPLAIN THE CLAIMS

A major problem in deciding which model might be correct is the absence of any direct information about the nature of the nuclear-active-environment. At this time, two important features seem to be important, the size of the nanodomain in which the reactions occur and the presence of a deuterium flux through this domain. The domain can apparently be made of any material in which hydrogen or deuterium can dissolve. Until the nature of the nuclear-active-state (NAS) is known, no theory will properly explain the effect and replication of the claims will remain difficult.

When fusion is initiated using conventional methods, significant tritium and neutrons are produced. In addition, when other elements are generated, they tend to be radioactive. This is in direct contrast to the experience using low energy methods. These products are almost completely absent and, instead, helium-4 is produced. When radiation is detected, it has a very low energy. This contrasting behavior, as well as the amount of anomalous energy, has made the claims hard to explain using conventional models. This difficulty has been amplified by a failure of many skeptics to recognize the contrasting effect of the environment, a plasma being used in the older studies and a solid lattice of periodic atoms being present as the new environment.

Over 500 models and their variations have been proposed, some of which are very novel and some are variations on conventional ideas. Most models attempt to explain the nuclear reaction once the required environment has been created, without addressing what that unique environment might be like. These models involve conversion of a proton (deuteron) to a neutron (dineutron), creation of an electron structure that is able to neutralize the barrier, conversion of deuterium to a wave which interacts without charge, and the presence of otherwise overlooked neutrons and/or novel particles. Many of the models will have to be abandoned or seriously modified once the nature of the nuclear active

environment is understood.

26) Reading the ERAB report again

Ludwik Kowalski (December 2002)
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

I have already written about the 1989 ERAB report -- a document prepared by the Energy Research Advisory Board for the DOE (U.S. Department of Energy). Detailed elaborations on various aspects of this report can be found in "Cold Fusion: The Scientific Fiasco of the Century," Oxford University Press, 2nd edition, Oxford, 1993. The author, John Huizenga, is a leading nuclear chemist from the University of Rochester; he was the chairman of ERAB. What follows is the executive summary of the report, as extracted from:

http://www.ncas.org/erab

Let me say again that, in my opinion, criticism of initial cold fusion claims was justified. There was no evidence that "excess heat" could easily be produced (even in a high school laboratory, as claimed by Fleischmann and Pons in March of 1989) or that the process producing excess heat was nuclear fusion responsible, for example, for solar energy. Most of those who now write about the so-called "cold fusion" agree that a high level of knowledge and skill are important to conduct research in that area. And nobody disagrees with the report main point that nuclear processes responsible for generation of anomalous energy (AE), if any, are very different from so-called "hot fusion." The report conclusion about the lack of convincing evidence for the practicality of AE also remains uncontested.

On the other hand, I think that it would be much better if the field was allowed to develop under ordinary conditions, for at least five years, before subjecting it to a special investigation by an officially appointed board. In my opinion, the report was not totally negative; it recognized the need for additional research and left the door open for possible later reconsideration. To make this clear I will underline significant phrases (see below) and insert short comments, using **BOLD CAPITAL LETTERS.**

* * * * * * * * * *

EXECUTIVE SUMMARY OF THE ERAB REPORT

As a result of the startling announcements in March 1989 by Utah scientists claiming the attainment of cold fusion, the Secretary of Energy requested (see Appendix 1.A) that the Energy Research Advisory Board (ERAB) convene a panel to assess the possibility of cold fusion. Since early May 1989, the Panel or subgroups thereof have participated in the Workshop on Cold Fusion in Santa Fe, have visited several laboratories, have studied the open literature and numerous privately distributed reports, and have participated in many discussions. The Panel meetings and schedule of laboratory visits are summarized in Appendix 1.B.

Since the above announcement, many laboratories worldwide have initiated research in cold fusion. In the United States, a major effort has been undertaken to search for cold fusion by a large number of research groups at university and national and industrial laboratories. Some laboratories support the Utah claims of excess heat production, usually for intermittent periods, but most report negative results. Those who claim excess heat do not find commensurate quantities of fusion products, such as neutrons or tritium, that should be by far the most sensitive signatures of fusion. Some laboratories have reported excess tritium. However, in these cases, no secondary or other primary nuclear particles are found, ruling out the known D+D reaction as the source of tritium. **IN OTHER WORDS, SOMETHING TOTALLY NEW MIGHT BE TAKING PLACE**.

The Panel concludes that the experimental results on excess heat from calorimetric cells reported to date do not present convincing evidence that useful sources of energy will result from the phenomena attributed to cold fusion. In addition, the Panel concludes that experiments reported to date do not present convincing evidence to associate the reported anomalous heat with a nuclear process.

Neutrons near background levels have been reported in some D_2O electrolysis and pressurized D_2 gas experiments, but at levels 10^{12} below the amounts required to explain the experiments claiming excess heat. Although these experiments have no apparent application to the production of useful energy, they would be of scientific interest if confirmed. Recent experiments, some employing more sophisticated counter arrangements and improved backgrounds, found no fusion products and placed upper limits on the fusion probability for these experiments, at levels well below the initial positive results. Hence, the Panel concludes that the present evidence for the discovery of a new nuclear process termed cold fusion is not persuasive.

The Panel also concludes that some observations attributed to cold fusion are not yet invalidated.

The Panel recommends against the establishment of special programs or research centers to develop cold fusion. However, there remain unresolved issues which may have interesting implications. The Panel is, therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system.

Following an introductory chapter, calorimetry, fusion products and materials are assessed in the next three chapters. Conclusions and recommendations are summarized in the final chapter.

CONCLUSIONS AND RECOMMENDATIONS

A. PREAMBLE

Ordinarily, new scientific discoveries are claimed to be consistent and reproducible; as a result, if the experiments are not complicated, the discovery can usually be confirmed or disproved in a few months. The claims of cold fusion, however, are unusual in that even the strongest proponents of cold fusion assert that the experiments, for unknown reasons, are not consistent and reproducible at the present time.

However, even a single short but valid cold fusion period would be revolutionary. As a result, it is difficult convincingly to resolve all cold fusion claims since, for example, any good experiment that fails to find cold fusion can be discounted as merely not working for unknown reasons. Likewise the failure of a theory to account for cold fusion can be discounted on the grounds that the correct explanation and theory has not been provided. Consequently, with the many contradictory existing claims it is not possible at this time to state categorically that all the claims for cold fusion have been convincingly either proved or disproved. Nonetheless, on balance, the Panel has reached the following conclusions and recommendations.

B. CONCLUSIONS

1. Based on the examination of published reports, reprints, numerous communications to the Panel and several site visits, the Panel concludes that the experimental results of excess heat from calorimetric cells reported to date do not present convincing evidence that useful sources of energy will result from the phenomena attributed to cold fusion.

2. A major fraction of experimenters making calorimetric measurements, either with open or closed cells, using Pd cathodes and D_2O, report neither excess heat nor fusion products. Others, however, report excess heat production and either no fusion products or fusion products at a level well below that implied by reported heat production. Internal inconsistencies and lack of predictability and reproducibility remain serious concerns.

In no case is the yield of fusion products commensurate with the claimed excess heat. In cases where tritium is reported, no secondary or primary nuclear particles are observed, ruling out the known D+D reaction as the source of tritium. The Panel concludes that the experiments reported to date do not present convincing evidence to associate the reported

anomalous heat with a nuclear process.

3. The early claims of fusion products (neutrons) at very low levels near background from DO electrolysis and D_2 gas experiments have no apparent application to the production of useful energy. if confirmed, these results would be of scientific interest. Recent experiments, some employing more sophisticated counter arrangements and improved backgrounds, found no fusion products and placed upper limits on the fusion probability for these experiments at levels well below the initial positive results. Based on these many

negative results and the marginal statistical significance of reported positive results the Panel concludes that the present evidence for the discovery of a new nuclear process termed cold fusion is not persuasive.

4. Current understanding of the very extensive literature of experimental and theoretical results for hydrogen in solids gives no support for the occurrence of cold fusion in solids. Specifically, no theoretical or experimental evidence suggests the existence of D-D distances shorter than that in the molecule D_2 or the achievement of "confinement" pressure above relatively modest levels. The known behavior of deuterium in solids does not give any support for the supposition that the fusion probability is enhanced by the presence of the palladium, titanium, or other elements.

5. Nuclear fusion at room temperature, of the type discussed in this report, would be contrary to all understanding gained of nuclear reactions in the last half century; it would require the invention of an entirely new nuclear process.

RECOMMENDATIONS

1. The Panel recommends against any special funding for the investigation of phenomena attributed to cold fusion. Hence, we recommend against the establishment of special programs or research centers to develop cold fusion. **BUT ORDINARY FUNDING WILL BE NEEDED.**
2. The Panel is sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system. **IN OTHER WORDS, COLD FUSION IS NOT A SPECIAL AREA OF SCIENCE, IT IS SCIENCE TO BE SUPPORTED BY FUNDING AGENCIES.**

3. The Panel recommends that the cold fusion research efforts in the area of heat production focus primarily on confirming or disproving reports of excess heat. Emphasis should be placed on calorimetry with closed systems and total gas recombination, use of alternative calorimetric methods, use of reasonably well characterized materials, exchange of materials between groups, and careful estimation of systematic and random errors. Cooperative experiments are encouraged to resolve some of the claims and counterclaims in calorimetry. **EXPERIMENTAL DATA OF THAT KIND ARE NOW AVAILABLE.**
4. A shortcoming of most experiments reporting excess heat is that they are not accompanied in the same cell by simultaneous monitoring for the production of fusion products. If the excess heat is to be attributed to fusion, such a claim should be supported by measurements of fusion products at commensurate levels. **EXPERIMENTAL DATA OF THAT KIND ARE NOW AVAILABLE.**
5. Investigations designed to check the reported observations of excess tritium in electrolytic cells are desirable.

6. Experiments reporting fusion products (e.g., neutrons) at a very low level, if confirmed, are of scientific interest but have no apparent current application to the production of useful energy. In view of the difficulty of these experiments, collaborative efforts are encouraged to maximize the detection efficiencies an to minimize the background. **DO BASIC SCIENCE AND WAIT FOR THE RESULTS BEFORE PROMISING ANYTHING PRACTICAL. IN OTHER WORDS DO NOT REPEAT MISTAKES MADE IN THE AREA OF HOT FUSION.**

27) Who Benefits from the Conspiracy?

Ludwik Kowalski (December 30, 2002)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07055

Return to the clickable list of items

About a week ago a teacher from an Internet discussion list wrote that a conspiracy against "cold fusion," if its claims are correct, can not possibly be effective, in a long run. This made me think about the institutional conspiracy against the religious reputation of Galileo. Two days ago I got a private message on the topic of institutional conspiracy from Dr. Edmund Storms. He is the one whose letter to the editors of Scientific American was posted as item #9 on my web site:

http://csam.montclair.edu/~kowalski/cf/

The reply was a reaction to what I wrote in items # 26 and #21. Thinking that those who read my “cold fusion” items might be interested in the episode described by Storms I asked for (and received) permission to share it. What follows is his story, and additional comments. In reading the story keep in mind that DOE stands for the (US Department of Energy), ERAB stands for the highly negative 1989 report of the Energy Research Advisory Board and BYU stands for Brigham Young University where S. Jones was conducting research. Storms wrote:

You might like to know that in 1995, Steve Jones and I submitted a proposal to the DOE to test the claims of Pons and Fleischmann. I, as a believer, would show Jones and Hansen at BYU, as skeptics, how to make the effect work and they would measure the resulting energy.

We did this believing the DOE would abide by the statement in the ERAB report that "The Panel is, therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system". This proposal was turned down. As far as I know, every proposal having anything to do with cold fusion was also turned down. For all practical purposes, the ERAB report killed the field in the US no matter what they said to the contrary.

The message with the permission to post had a comment which, I suppose, can be added as an elaboration on the above. I wrote:

4) . . . The fact that DOE took a very hard stand in 1995 does not mean one should give up. Let us hope that 2003 will the year of the beginning of a reconciliation. . . .

Dr. Storms responded:
Like you, I hope for sooner rather than later. However, government bureaucrats and academics have invested so much in rejecting this idea that it is not possible for

them to change. I expect the US will change only after Japan solves the problem and threatens to create a commercial product based on the process. Meanwhile the old will die off and administrations will change, allowing new people to take control of science. It is a very slow process to make such profound changes. Being retired, I look upon this as an interesting process with very little likelihood of an end any time soon.

Hmm, more than 1000 scientific papers supporting the reality of highly unusual phenomena are available but the leaders of our scientific establishments refuse to have another look. Something is not right. What should a confused science teacher do? Avoid the topic because authorities declared it to be non scientific 13 years ago? Risk his or her reputation and try to discuss the issue objectively? Play it safe and support official pronouncements? Those invited to look into Galileo's telescope were in a similar situation.

The more I think about it the more I am convinced that something similar to what was suggested in item #21 (on my web site above) is urgently needed. Read again what Dr. Storms wrote in the letter to the editors of Scientific American (item #9 on my web site) and think about it critically. Is he right or is he wrong that the issue is important in the context of support for science in our society?

By the way, a TV program last night was devoted to illnesses. They produced an example of institutional conspiracy against a researcher. The man had data proving that children's exposure to lead (mainly from gasoline emission) affected mental functioning. But the powerful lead industry launched an attack against him, and tried to discredit him. It took three years to show that his claims were not pseudo-science. Lead was removed from gasoline and its concentration in air has been reduced significantly. The motive of conspiracy, in this case, was obvious. But what motivates the DOE? Why was "every proposal having anything to do with cold fusion ... turned down" by our own government? Why do they ignore hundreds of serious papers authored, mostly (I assume) by highly trained Ph.D.. scientists? Is the scientific establishment trying to protect us from some dangers? Why do they oppose a fair examination of the AE claims, in view of new evidence? Despite its criticism, which has been mostly justified, the ERAB report was “sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system." Is it true that such support has not been available to reputable US scientists? Why not?

28) A summary of another recent report

Ludwik Kowalski (January 2, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

Do you remember the article of A.B. Karabut which I translated in item # 13? He showed that generation of excess heat in a gas discharge tube (in which a Pd cathode was bombarded by ~ 1KeV D ions) was accompanied by emission of highly unusual alpha particles (14 MeV) and protons (3 MeV). Such particles were also observed in an electrochemical setup producing excess heat, as reported by A.G. Lipson et al. at the 9th International Conference on Cold Fusion (May, 2002, Beijing, China). The report can be downloaded from the library at the LENR-CANR site:

http://lenr-canr.org/Features.htm

Before summarizing the paper let me mention two prestigious laboratories with which the authors are affiliated. One lab is at the Department of Nuclear, Plasma and Radiological Engineering at the University of Illinois at Urbaba-Champaign and another is at Lebedev Physics Institute in Moscow. The authors refer to an earlier study (2001) in which alpha particles and protons were found to accompany generation of heat from the "Au/Pd/PdO:D(H) heterostructure." Alpha particles with energies between 8 and 14 MeV were identified with a set Si detectors, after the Pd cathode was removed from the electrolyte. In this study, on the other hand, the emission of unusual nuclear particles was observed during the electrolytic loading. Use of Si detectors in the liquid electrolyte would be very difficult and a different method of detection was used to identify particles, and to estimate their energies.

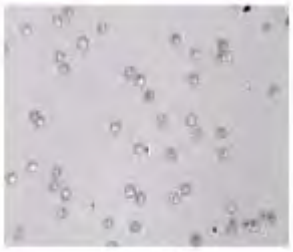

Figure 3

Note:
Figures are numbered
as in the original paper.

That method is often used to detect alpha particles (energies below 8 MeV) emitted from radon and thoron, present in air, and from their descendants. A special plastic material, commercially available under the

name of CR-39, is exposed to alpha particles and then etched in hot NaOH for several hours. After that procedure the plastic sheet is examined under the microscope. It turns out that places damaged by alpha particles become visibly pits, as shown in Figure 3 below. Thus, the number of intercepted particles can be determined by counting the number of pits per unit area. By using alpha particles with energies between 2 and 29 MeV the authors established a relation between the pit diameters and energies, as illustrated in Figure 1. A similar curve was obtained for protons with energies between 0.7 and 3 MeV. Beams of alpha particles and protons, used to calibrate the CR-39 detectors, were produced with accelerators in Dubna, Russia.

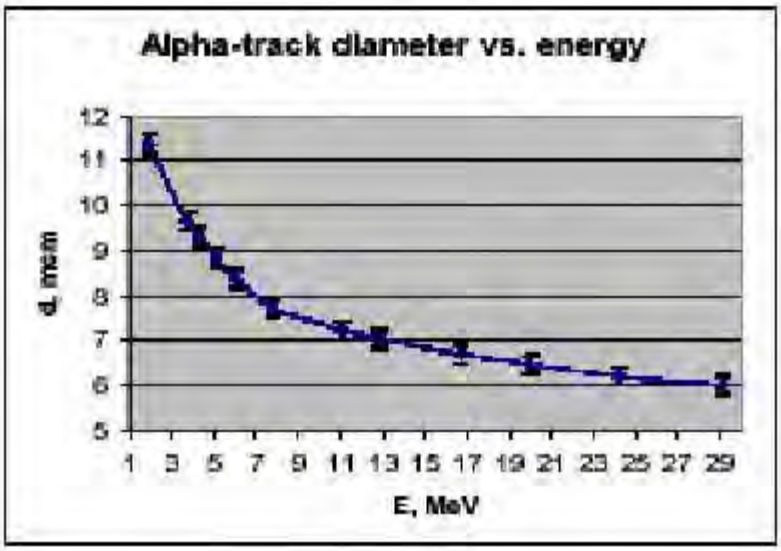

Figure 1

In the electrolysis experiments some sheets of CR-39 were in contact with the Pd cathode while others were kept away from the cathode to measure the background. As expected, background sheets revealed presence of a small number of alpha particles the radon and thoron series. Plastic sheets designed to detect protons were coated with Cu foils whose thickness was 25 microns. Such foils stop all alpha particles below 9 MeV but transmit protons above 2.3 MeV.

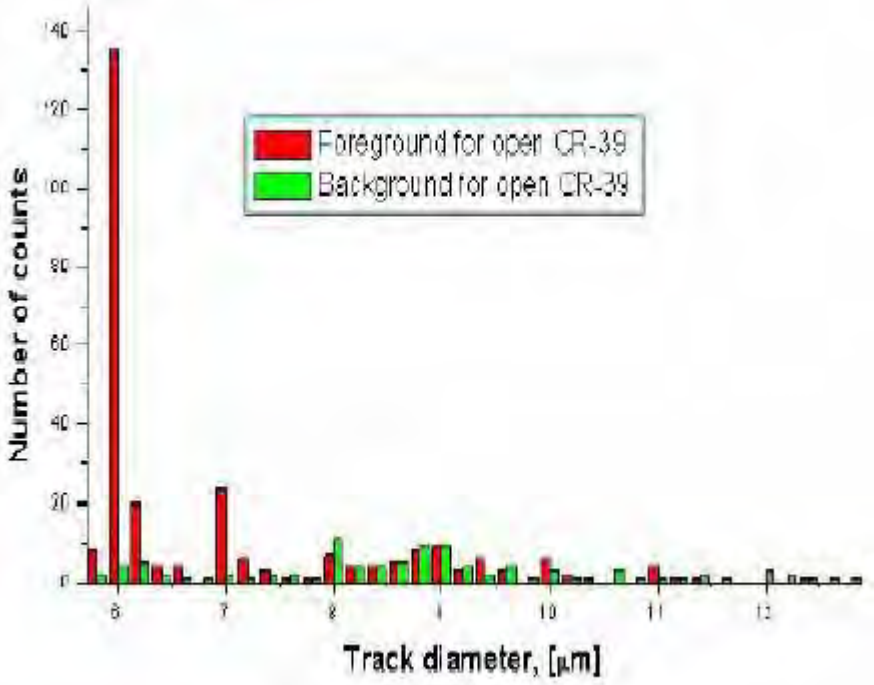

Figure 6

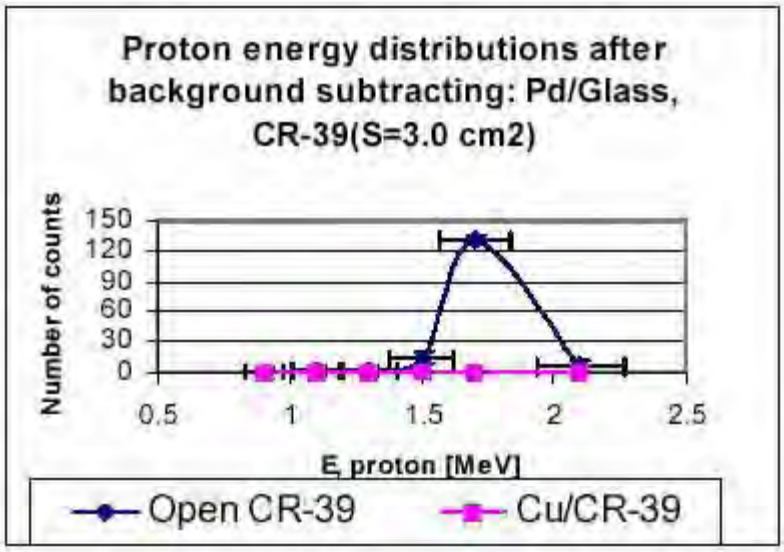
The results, for the CR-39 sheets which were not coated with copper, are shown in Figure 6. Red bars refer to sheets which were in contact with the cathode while green bars refer to sheets measuring the background. It is clear that in the area of small pits (high energy alpha particles and nearly all protons) the background is very small in comparison with the emission from the cathode. The mean energy of dominant alpha particles was close to 14 MeV while that of protons was close to 1.6 MeV. The estimated emission rates were about 7 (per m^2 per second) for alpha particles and about twice as much for protons. The energy distribution of protons is shown in the next figure.



The authors conclude that the "observed effect of long-range alpha and proton emission cannot be described in terms of nor natural alpha-nuclides contamination in Pd neither the cosmic ray interactions with cathode." I was really impressed; the study does confirm the reality of an unusual nuclear process. It made me think about the old Geiger-Nuttall rule (the inverse correlation between the energy and half-life, later explained in terms of quantum mechanical tunneling). I think that the above observations are sufficiently important to justify building a special Si detectors telescope with a thin window and using it

instead of CR-39, in the liquid.

How do researchers who conducted this study differ from mainstream scientists? Would the DOE or NSF approve a research grant seeking to further investigate the unexplained phenomenon?

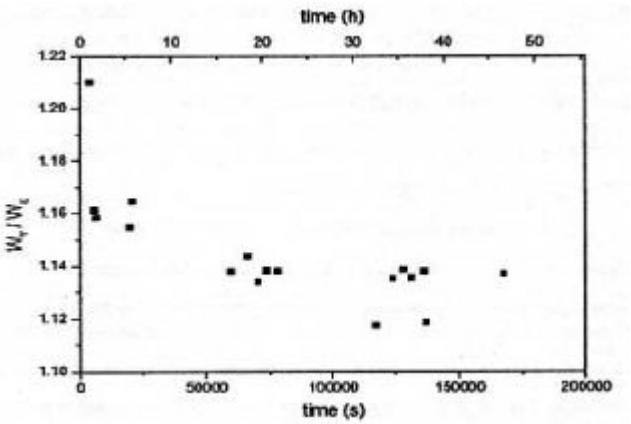
29) Another manifestation of excess heat

Ludwik Kowalski (January 4, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

A strange device for generation of excess heat was built by Jack Dufour et al. from the Laboratoire Des Sciences Nucleaires at CNAM in Paris. The device was described at ICENES2002 (11th International Conference on Emerging Nuclear Energy Systems in Albuquerque, NM, October 2002.) It was a copper pipe inside a steel pipe with some Sn/Pb solder between them (70% lead). The length of each pipe was about 17 cm. The outer diameter of the copper pipe was 14 mm while the inner diameter of the steel pipe was 14.2 mm.

The set of two pipes was used as a conductor through which a known electric current was allowed to flow from a dc generator. The potential difference, typically 5 V, across the pipes, as well as the current, were constantly monitored. The amount of heat produced in the pipes was measured by using a flow calorimeter. Water was flowing through the copper pipe, at a measured rate, and the temperature of pipes was allowed to reach a constant value (typically one hour) . The water temperature was measured at the input and at the output. The calorimetric parameters were then used to calculate W_t, the rate at which heat was generated. It turned out that W_t was higher that the rate at which electric energy was supplied, W_e (for example, 12 W at 5 V).



The excess heat ratio, defined as $p=(W_t/We)$, was found to increase with the magnitude of the electric current. At the highest current used in the experiment the value of p was 1.21. A progressive decrease of p, attributed to a decrease of current during a two-days-long experiment, is illustrated in the figure. The values of p, in a steady state, are always larger than unity; the excess heat was never smaller that twelve percent of supplied energy.

My description of the apparatus was slightly simplified; the outer surface of the steel pipe was also cooled by circulated water and temperatures were measured in several different locations (to determine gradients). Furthermore, the system was equipped with a calibration solenoid; it was used to heat the pipes inductively rather than ohmically. The authors claim that the excess heat is not an artifact due to a systematic error; I

am taking this for granted. What else can one do without having a possibility to examine the apparatus, and the procedures used to evaluate W_e and W_t? Speculations about the nuclear origin of excess heat were presented but I am ignoring them because no evidence was offered. This, however, should not be a justification for rejecting what has actually been established -- the excess heat.

In one experiment, lasting several days, the excess heat was 520 kJ. The authors argued that the oxidation of metals, which were only slightly tarnished, or any other chemical process, could not possible be responsible for a significant contribution to excess heat. The pipes would have to be 91% oxidized to release 520 kJ of chemical energy. Tarnishing, however, indicates that the oxidation affected only a small fraction of one percent of metals. That is why the chemical origin of the anomalous energy was rejected by the authors.

My summary is based on what has been published in the ICENES2002 proceedings (pages 367 to 373). The e-mail address of Jacques Dufour, listed in the proceedings, is dufourj@cnam.fr I attended the conference and had a chance of talking with Jacques after his presentation. He said that the attitude of French mainstream scientists toward the so-called “cold fusion” field is becoming more and more positive.

30) American Physical Society Guidelines

Ludwik Kowalski (January 5, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ

Return to the clickable list of items

The January 2003 issue of Physics Today has an interesting item entitled "New APS Ethics Guidelines Address Research, Misconduct and Professional Responsibilities." The author, Jim Dawson, summarizes main points of the **new ethics guidelines** recently adopted by the American Physical Society (APS) panel on public affairs. I was particularly interested in this segment:

"You should hang on to your data, you should respond to inquiries from other scientists, and you should be responsible as a referee. . . The new guidelines, approved on 10 November, come in several parts. A policy statement on how to handle allegations of research misconduct defines misconduct as 'fabrication, falsification, or plagiarism in proposing, performing, or reviewing research, or in reporting research results. .....' Such behavior is termed an 'egregious departure from the expected norms of scientific conduct that can lead other scientists along fruitless paths.' It also 'diminishes the vital trust that scientists have in each other' and undermines public confidence in science. The statement goes on to say, 'It is imperative ..... that the institutions responsible for funding and performance of scientific research, as well as the relevant professional societies, take appropriate steps to discourage such conduct and have policies and procedures in place to deal with allegations of misconduct.' "

I find these remarks encouraging; they indicate that APS wants to defend fairness. But how should one interpret the above in the context of the so-called "cold fusion" issue? Considering what has been accomplished in that area (hundreds of scientific reports from recognized experts in several countries) I would like to suggest that the APS initiate the process of reevaluation of the entire field. The 1989 ERAB report was correct in stating that no convincing evidence existed to support the premature claim of Fleischmann and Pons that a new source of useful energy had been discovered.

But the situation has changed in the last ten years. Scientists conducting research in this area have accepted the criticism; they no longer claim that demonstrations of excess heat are easy (as initially announced) or that the underlying mechanism is simply a fusion of two nuclei, as in hot plasma. But they "hang on to data" indicating that something new was discovered, but not understood, in 1989. I see no evidence that the data were "fabricated" or that the methodologies they now use constitute a "departure from the expected norms." Is it true that editors of many peer reviewed journals automatically reject manuscripts dealing with "cold fusion?" Is it true that "institutions responsible for the funding and performance of

scientific research," such as DOE and NSF, automatically reject research proposals dealing with "cold fusion?"

I have heard such allegations from several "cold fusion" scientists. They claim that the entire field has been blacklisted in the US. If this is true, then, in my opinion, the situation should be reviewed in light of new ethical guidelines. Those guilty of falsifications should be exposed as pseudo-scientists while those who made "honest errors" should be criticized, as in any other field of science. And those whose claims are accepted as valid should be rewarded (in the form of published papers and financial support) as in any other area of science.

As a physics teacher I am confused by the situation. What should we tell students when they ask about the discovery of Fleischmann and Pons? Most teachers have no time and no means to validate claims made in the area of "cold fusion," and need guidance. An objective summary of what has been done in that field in the last ten years would help us to describe it correctly. The issue is not only scientific; it is a topic of general interest.
Most educated people know about the "cold fusion episode" and opinions about it are divided. Some say it was "a fiasco" while others say it was a "real discovery" of something very important. How should teachers address this topic in the context of "public affairs between science and society," or in the context of "institutional support for new ideas and innovations?"

PS (April 29, 2003):
Last January, immediately after Dawson's article was published, I sent a letter to the editor to Physics Today. It was a suggestion to reevaluate the field of cold fusion (for the benefit of teachers). The letter linked this issue with "new ethics guidelines" adopted by APS. I have not heard from the editor; will they publish my letter? Will they write to me explaining why the letter was not published or will they simply ignore me? I also wrote a note about cold fusion to The Physics Teacher. The editor did sent it to two referees and informed me about their advice for not publishing the note. I will wait another month or two. After that my letter to the editor of Physics today will be appended here.

31) My own excess heat experiments

Ludwik Kowalski (January 8, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

There was no evidence for "excess heat" in my experiments. That is the bottom line. And here are some details. Inspired by the paper of Jacques Dufour (see item #29) I decided to conduct my own search for excess heat. Is it conceivable that excess heat is more common than we think? How do we know that a TV set, for example, produces as much heat as the amount of electric energy it receives in any specified time interval? In principle this can be verified by measuring both the heat released, W_t and the electric energy received, W_e. But I doubt that anyone has ever bothered to accurately measure the W_t released from a TV set. We just know that it should be the same as W_e. The equality of W_t and W_e is often verified in an introductory physics laboratory by using the so-called electric calorimeter and a metallic resistor. I do not know of a similar test performed by using a resistor made from a composite material.

Such tests were probably performed many times. Instead of looking for a reference I conducted my own simple experiment. I took a radio resistor (nominally 10,000 ohms but in reality 9,720 ohms, at room temperature) and placed it into a common water-based student calorimeter. The resistance in water dropped immediately, indicating that some current was flowing through the water. To prevent this the metallic leads of the resistor were coated with a nonconductive glue. I was surprised to find that W_e and W_t were identical to within 0.1%; the accuracy of my measurements was at the level of about one or two percent. But, as fortune cookies tell us, one can be lucky on some days.

This made me think of a possible physics research project for a group of high school students. The topic can be introduced by saying that "scientists claim that excess heat can be generated in some electrical setups and that not all conceivable setups have been tested." This would give students an opportunity to learn about the history of the so-called "cold fusion" and lead to more sophisticated experiments in which W_t is said to be larger that W_e. I know of one scientist who is working on a document describing elementary excess heat experiments. He said that laboratory instructions should be ready at the end of this month. Such materials would be of great value to us. I would be happy to post his pamphlet as an item on this web site for teachers interested in "cold fusion."

I will, of course, try to perform the experiments myself. This would give me an opportunity to be in a much better position to argue about the non reality or reality of the so-called "anomalous energy." If I am convinced, on the basis of my own measurements, that the excess heat is real then I would be more interested in theoretical explanations which are being offered to explain it. I would also become more optimistic about the prospect of using nuclear energy without producing dangerous nuclear waste products. Inspired by their own observations students are likely to think in the same way. And who knows, perhaps a biography of another Marie, in the next century, will begin by describing a high school physics project which inspired her. Will the scientist's name be Marie or will it be Thomas?

P.S.
Another conducting material tested for the hypothetical “excess heat’ was carbon-impregnated paper available from Pasco Scientific. That paper is often used by by students to model electrostatic fields. I allowed a direct current of about 50 mA to pass through a flat 3.2 kiloohms resistor inside a calorimeter for 40 minutes. The amount of heat released did not differ from the electric energy supplied by more than 3%; the expected sensitivity of the experiment. A student project of that kind can be very instructive.

32) Another case

Ludwik Kowalski (January 6, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

In reading anomalous energy (AE) publications, available over the Internet, I keep asking myself the same questions. Why do many scientists still claim that the AE field is mostly nonsense? What makes the AE publications different from those found in mainstream journals? Why is the status of the AE not reevaluated in light of new data? Will the new APS Ethics Guidelines (Physics Today, January, 2003, p20) change the attitude of individuals and organizations toward a field which seems to be interesting and important? The article which prompted me to ask these questions again was written in 1999. The title is "My Life With Cold Fusion as a Reluctant Mistress. " You can find the article on the web site of E. Storms:

http://home.netcom.com/~storms2/index.html

Even those who are not prepared to deal with some technical details (like myself) will appreciate the main points, and interesting reflections of a highly competent scientist. I strongly recommend this article to all those who are interested in AE. Storms writes that "the phenomenon called 'cold fusion' has been duplicated hundreds of times in laboratories throughout the world and the subject has been discussed in over 3000 papers . . . Unfortunately, because of the rejecting attitude of conventional scientists, much of this information is not available in scientific journals." After listing previously unrecognized metallurgical factors, influencing either success of failure of an AE experiment in the electrolytic PdD systems, Storms writes:

"What can I conclude from this experience? First, the phenomenon claimed by Pons and Fleischmann is real, but it is only a small part of a much larger picture. The reality of this phenomena has an even greater importance to science and technology than was ordinarily proposed. Second, the method used by Pons-Fleischmann is useless for eventual production of commercial power. Active palladium is too difficult to find and conditions are too sensitive to impurities. Nevertheless, it is a very useful and inexpensive method to explore certain aspects of the phenomena. . . . And third, the field is sick and on life support. . . .

The amazing claims for [nuclear] transmutation are getting increased attention and are accumulating experimental support, but acceptance is hard to find even in the cold fusion community. These claims require expensive tools to show their reality - money that is not generally available. The only solutions are for the Patent Office to change its approach and/or for individuals or companies to provide funds toward a basic understanding without an immediate guarantee of financial return; several very unlikely possibilities."

By the way, Dr. Edmund Storms is a radiochemist who worked on important projects at Los Alamos

National Laboratory for thirty-four years. He is a recognized authority in the field of material science, as reflected in several books, and in over seventy research publications. But even a person of that caliber was not able to publish an important paper in Physical Review, in Review of Modern Physics and in two other journals. The PR editor rejected the paper because “we do not publish reviews” while the editor of RMP wrote “Cold fusion is a classic example of pathological science. I will certainly not publish articles supporting its disproven claims.” Apparently this is a typical case; AE scientists are not given a chance of sharing their data with the rest of us. We are being protected from them by editors and administrators. Something is not right with this.

The title of the rejected 2001 paper was: “Cold Fusion: an Objective Assement.” It is avaialble as a downloadable file: StormsEcoldfusionc.pdf at

http://lenr-canr.org./Features.htm

Why was this paper labeled “pathological science?” Read about the new APS Ethics Guidelines; they do address the issue of professional responsibilities. (The article summarizing the guidlines, as indicated above, can be found on page 20 of the January 2003 issue of Physics Today.)

33) Julian Schwinger and cold fusion

Ludwik Kowalski (January 8, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ

Return to the clickable list of items

1) Let me insert the entire message e-mailed to me be Edmund Storms; I only quoted from it last night (see item 31). Referring to my inquiry into unjustified rejections of "cold fusion" papers Storms wrote:

REJECTION HISTORY OF THE PAPER "COLD FUSION: AN OBJECTIVE ASSESSMENT" by Edmund Storms

A paper called "Whatever Happened to Cold Fusion" was submitted to the following journals as a proposed paper. The full text paper was offered if interest were expressed. No requests were made. Submission was done in series, with a new journal chosen after a rejection. During this process, the paper was completed and retitled "Cold Fusion: An Objective Assessment". The purpose of this exercise was to discover whether a scholarly review of cold fusion could be published in a major scientific journal and the reasons why not if it were rejected. When objections were raised about the reasons for rejection, these were not answered by the rejecting editor.

Journal	Submitted	Rejected	Reasons
Phys Rev. B	6/10/01	7/11/01	Said the Phys. Rev. does not publish reviews, although this is not true if the subject is to their liking.
Rev. Modern Phys.	7/25/01	8/10/01	Editor rejected the paper with the comment "Cold fusion is a classic example of pathological science. I will certainly not publish articles supporting its disproven claims."
Chem. Rev.	8/24/01	11/20/01	Three of four reviewers rejected the paper because they did not think cold fusion is real and could not trust me to be unbiased in arguing this belief.
J.Electroanal.Chem.	11/23/01	12/3/01	Editors did not think the subject was appropriate

to the journal.

2) How would Richard Feynman react to the announcement of the so-called “cold fusion” if he did not die a year earlier? I suspect he would not reject an experimental discovery on the basis of the absence of a theoretical explanation. He would probably do the same things, more or less, as Julian Schwinger, his 1965 Nobel prize colaureate. Schwinger’s two addresses on the subject can be downloaded as pdf files from the library at:

http://lenr-canr.com/Features.htm

In one of the addresses the great theoretician wrote: “It may not be too much of an exaggeration to say that, early in April, 1989, everyone – including those who, like myself, had to look up the meaning of enthalpy – had thrown together and electrolysis apparatus and was waiting for dividends. After a few weeks, with no reward, they quit in disgust, and denounced it all as incompetence, or fraud. Their votes are irrelevant.

Reproducibility is often cited as a canon of science. And so it is, in established areas. But, early in a study of a new phenomenon that involves an ill-understood macroscopic control of a microscopic mechanism, irreproducibility is not unknown. That was so at the onset of microchip studies. It also appeared in the initial phase of the discovery of high temperature superconductivity, which, by the way, is a prime example of “embracing the concept” without having “to understand the mechanism.”

After discussing objections raised against “cold fusion” Schwinger observed: “Imagine, then, a small but macroscopic piece of the lattice absorbs the excess energy of the HD or DD reaction. Please--I beg of you--do not rise in high dudgeon to protest that this is impossible because of the great disparity between atomic and nuclear energy scales. That is a primitive reaction to what may be a very sophisticated mechanism. And do not forget the failure of theory to predict, and then to account for the phenomenon of high temperature superconductivity. I advance the idea of the lattice playing a vital role as a *hypothesis*. Past experience dictates that I remind you that a hypothesis is not something to be proved mathematically. Rather, it is a basis for correlating data and for proposing new tests, which, by their success or failure, support or discredit the validity of the hypothesis. It is the essence of the scientific method..... The pressure for conformity is enormous. I have experienced it in editors’ rejection of submitted papers, based on venomous criticism of anonymous referees. The replacement of impartial reviewing by censorship will be the death of science.” Schwinger died in 1994.

34) A way to demonstrate reality of CANR

Ludwik Kowalski (January 11, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ

Return to the clickable list of items

After reading the "**Cold fusion: an objective assessment**" again I would like to focus on some aspects of this four-times-rejected paper of Edmund Storms. It was a reasonable summary of progress, about three years ago.

Storms has a table listing various experimental approaches to chemically assisted nuclear reactions (CANR). These approaches are:

1. Electrolysis of D_2O (H_2O)-based electrolyte using a Pd, Pt, Ti, or Ni cathode; (This is the original P-F method, which has been duplicated hundreds of times to produce claimed AE and NP in every country where the method has been studied.)

2. Electrolysis of KCl-LiCl-LiD (fused salt) electrolyte using a Pd anode; (This method has been difficult to duplicate.)

3. Electrolysis of various solid compounds in D_2 (Proton conduction); (This method has been duplicated in the US, Japan and France to produce AE.)

4. Gas discharge (low energy ions) using Pd electrodes in D_2 (H_2); (Variations on this method have reported AE and NP in the US, Russia and Japan.)

5. Ion bombardment (high energy ions) of various metals by D+; (Variations on this method have reported NP in Russia and Japan.)

6. Gas reaction (H_2) with Ni under special conditions; (Replicated independently several times in Italy to produce NP and AE.)

7. Cavitation reaction involving D_2O and various metals using an acoustic field. (This method has been replicated in the US to produce NP and AE.)

8. Cavitation reaction in H_2O using micro bubble formation; (Several attempts to duplicate variations on the method have failed.)

9. Reaction of finely divided palladium with pressurized deuterium gas; (Variations on this method have produced NP and AE in the US and Japan.)

10. Plasma discharge under D_2O or H_2O; (Variations on this method have produced AP and NP in the US, Italy and Japan.)

11. Phase change or a chemical reaction, both involving compounds of deuterium; (NP production has been reported in the US and in Russia)

12. Biological Systems based on living cultures; (NP has been reported in Japan, Russia and France.)

After producing this list the author describes some of the methods and the results obtained. Addressing the issue of the nuclear origin of excess heat he points out that neutrons and tritium, the main reaction product of the so-called “hot fusion”, are relatively rare in CANR. Their rates of emission would have to increased by many orders of magnitude in order to be commensurable with the rate of generation of “excess heat.” The same seems to be true for the 14 MeV alpha particles and 3 MeV protons. But ^{4}He is accumulated at much higher rate and it may be the main reaction product. The same seems to be true for some heavy nuclides (according to Karabut).

The difficulty with the main products, as emphasized by Storms, is their very low level of concentration, typically several hundreds of ppm, after hundreds of hours of accumulation. If it were up to me I would focus on one product, alpha particles of 14 MeV. I know of two papers in which such particles (and 3 MeV protons) were observed. The authors of these papers (Lipson ... and Karabut...) used very different CANR setups but they observed essentially the same kind of energetic light particles. What can be more convincing, of the reality of CANR, than alpha particles of 14 MeV? That energy can not be attributed concentration of naturally occurring emitters, such Rn, Tn and their daughters. I also read a paper of J. Dash, from Portland State University, in which a chamber similar that of Karabut was used. A uranium foil, attached to the cathode, was found to be four times more alpha-radioactive after 550 hours of bombardment by D_2 ions (500 V and 5 mA) than before the bombardment. The energies of alpha particles, however, were not reported.

Unfortunately, the most direct method of particle identifications (a setup of two Si detectors) could not be used in the reacting environment (electrolytic cell of Lipson or a gas discharge chamber of Karabut). Therefore the authors used less direct methods of measuring energies of alpha particles. They did the best they could under the limitations of methods #1 and #4 listed by Storm. The method # 9, however, is likely to be amenable to the use of a single solid state detector. A silicon detector, placed one or two millimeters away from a layer of powder, could be used, even when the gas pressure is increased to several atmospheres. If it were up to me I would mobilize several teams to conduct such experiments. Observation of 14 MeV alpha particles would be a highly convincing argument that nuclear reactions can be induced by chemical means. This would be an important scientific contribution, the first step toward a normal process of exploring a phenomenon by going from known to unknown. The unfortunate period in which “cold fusion” investigators were treated as pseudo scientists, or as dishonest manipulators, would end by recognizing the reality CANR.

Return to the clickable list of items

35) Another nuclear signature

Ludwik Kowalski (January 12, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

Another unique nuclear signature of the so-called "cold fusion," able to prove the reality of CANR, is emission of gamma rays, as reported by many researchers. According to Karabut, for example, gamma rays can be observed from a gas discharge tube filled with deuterium and equipped with a palladium cathode. Presence of gamma rays should be relatively easy to either confirm or to deny. The low level gamma radiation takes place during the discharge, and up to height days after the discharge. Looking for gamma rays after the discharge can first be conducted by using a common Geiger counter (with appropriate filters) and then with a more sophisticated detector able to identify numerous peaks presumably due to specific transmutation products.

The methodology for trying to establish reality CANR (chemically assisted nuclear events) should be similar to that used in statistics. Start with the so-called "null hypothesis," that is assume that an observed phenomenon is not due to a nuclear process. Do everything possible to show that it can be explained by a non-nuclear effect. Failure to show this, (not only by me but also by knowledgeable scientists investigating the results), would be an acceptable argument in favor of CANR. In the case of the low level gamma rays, for example, one would have to rule out a possibility that they come from a contamination of some kind or that what is believed to be gamma rays is actually noise, etc.

The opposite approach would be to take seriously all indications which can possibly be interpreted in terms of what one wants to demonstrate. Let me give an illustrations of this. A claim is made that the operation a TV is associated with nuclear reactions. A person who believes in this claim sets up a demonstration. Two identical TV sets are placed in a room. One of them is on while another off. After a month or so a paper tissue is used to remove the dust accumulated on each screen. The tissue used to clean the operating TV turns out to be radioactive (about five times above the background level, as in my home) while the other tissue is not radioactive. This reproducible fact, however, has nothing to do with nuclear processes being activated by the operation of a TV set. It has to do with ions of radon (and its daughters) in the air, and with their natural migration along the electric field lines toward the charged surface of the operating TV set.

I am assuming that honest scientists conducting research in the area of "cold fusion" are objective and that they do not fall into a trap of ignoring possibilities of alternative explanations. But suppose that this assumption is contradicted and that the apparently nuclear signatures, claimed to be highly significant by hundreds of specialists, are finally shown to be either nonexistent or misinterpreted. This would indicate that a phenomenon of large scale self-deception, and mutual support, is a real possibility in any area of science. I wander if criticism of other people work is common within the "cold fusion" community. How does this community deal with real fraud and deception likely to occur in any area? I suspect that there may be a tendency not to publicize disagreements, and fraudulent data, in order to protect the field from possible "bad publicity." But who knows, perhaps I am wrong on this.

Let me end with an interesting observation; it was influenced by Jacques Dufour's paper which I summarized as item # 29. He asked: why is it that CANR are so difficult to prove? And the answer was: "[because] "trace amounts of byproducts are expected. To eliminate all problems of initial impurities present in the metal, and to be well above the detection limits of the instruments, will require to further increase the energy production and to run experiments on very long periods." It is well known that detection limits for radioactive substances are usually by many orders of magnitude lower than for stable substances. But the reaction products of "cold fusion" are mostly stable. This presents experimental difficulties. On the other hand, nuclear reactions generating energy without producing radioactive waste are highly desirable. According to Dufour, "this is a drawback to convince of the reality of the phenomenon, but a considerable advantage when uses are envisaged."

Here are simple numerical illustration for an introductory science course. Suppose that excess heat is generated at the rate of 10 W, as in some “cold fusion” experiments. Also suppose that each nuclear event produces 6 MeV of energy; this translates into about 10^{-12} joules per event. How many events would occur in each second? The answer is: $10/10^{-12}$ or 10^{13}. Suppose that X is the only byproduct of a nuclear event. In that case the amount of X accumulated in each second would be 10^{13} atoms. The number of atoms accumulated in ten hours would be $3.6*10^{17}$ (or 2.4 micrograms, if X were ^{4}He). If X were a radioactive product, characterized by the half-life of ten thousand years, then the disintegration rate would be $7.88*10^{5}$ per second.

36) Personal reflections of George Miley

Ludwik Kowalski (January 12, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ 07043

Return to the clickable list of items

Those who are interested in sociology of cold fusion (ethical and political aspects), should definitely read the article of George Miley. That article deals with ethical issues associated with "cold fusion." It can be downloaded (as a 10-pages long pdf file) from the library at this web site:

http://canr-lenr.org/Features.htm

I met George at the recent International Conference on Emerging Nuclear Energy Systems (Albuquerque, 2002) where he presented a paper entitled: "Low Energy Reaction Cell for Portable Power." Miley thinks that "Low Energy Nuclear Reactions (LENR) potentially offer a radical new approach that could provide portable power units in the 1-50 kW range." He is a coauthor of the paper which I summarized in item #28. This paper, and earlier references found there, describe experiments demonstrating nuclear processes in cold fusion setups.

Section 1 of the article, entitled "Personal Reflection," describes the early cold fusion meetings at which Miley participated; he was the editor of three scientific journals: Fusion Technology (FT), Laser and Particle Beams, and Journal of Plasma Physics. He wrote, for example,: "Then there was the famous NSF-EPRI meeting in Washington DC where the NSF ended up withdrawing 'official' sponsorship at the last moment due to the swing in opinion against CF. Despite this controversy, Edward Teller attended this meeting in a wheel chair (due to a recent operation) and provided a guiding example of an open scientific mind by freely entering the discussion." Section 2, entitled "Publication Policies and Related Issues" deals with important issues facing editors of scientific journals.

In that section Miley wrote: "Soon scientific sentiment turned against CF, and editors of *Nature* and the APS Physics journals quickly took the stance that CF did not have a "scientific" base. Thus, they would not even send papers on the topic out for review, shutting the door for any CF papers in these key journals. Despite that example, I stuck with the original decision that papers passing review should appear in *FT*. As a result, by default, *FT* virtually "cornered" the market for CF papers! A backlash quickly followed, with "hot fusion" members of the *FT* editorial advisory board and some readers vocally questioning my decision. Some declared these papers would "destroy" the journal. At that time, I strongly reiterated (and continue to do so) that the purpose of a journal is to communicate basic science and technology so that papers which can pass review should be published as long as the topic is consistent with journal coverage. I emphasized that I did not feel that I had the right as editor to arbitrarily turn papers away because they were from a 'questionable' field. . . .

Another criticism of my editorial policy on CF has been that since I have done research on the topic, I must be biased in favor of it. It's true that I have had papers in most ICCF meetings, starting from the original LANL meeting in Santa Fe. This criticism, in my view, amounts to a double standard. My initial selection as *FT's* editor, and the other two journals, was based on my recognized research on fusion, lasers, and plasma physics. This track record was assumed to provide me with better insight into the technical content of the papers, and allow me to select top reviewers. In universities, teaching and research are well recognized as reinforcing each other. The same is certainly true for editing and research. Why wouldn't the same be true for CF? Again, this ethical issue is left to the reader to consider, namely, do we want general managers as journal editors or, do we want experts from the field, despite possible conflicts of interest? In conclusion, the issue of whether my *FT* position, as opposed to *Nature*'s closed-door policy, is proper for a scientific journal must be left to the reader."

The next three sections deal with the role of the Internet as a vehicle of scientific communication. Miley writes: “Clearly the web bulletin boards fill a very important role for rapid scientific exchanges. However, this is best used in a concurrent flow of papers through peer-reviewed journals. The review process is time consuming, but it serves to sort out and distill the fundamental results, providing for a more calmed deliberate interchange that ultimately enhances scientific progress in the field. The unfortunate refusal of editors to receive CF papers disrupted the normal system, and left the bulletin board crowd in charge. Without a counter-balance for peer review (except for *FT* which could not handle this volume and variety of topics involved), CF was left in a confused state. It is difficult, if not impossible, to sort through the bulletin board materials to focus on real issues. Now that bulletin boards of this type have spread widely, we can expect an even more explosive and disastrous episode if a situation like the CF news announcement occurs again. The best defense against reoccurrence of a CF-type episode in the future is for the major journals to assume their rightful role of an “open door” for papers passing peer review.”

Section 6, entitled Scientific Integrity and Openness,” is also very interesting. Integrity means honesty, openness means not hiding proprietary information before patenting and not having industrial secrets. The author writes: “Let us now turn to issues of scientific integrity. Integrity, in the sense of avoiding fraud, has been an all too frequent topic of discussion in the CF field. Some even accused Pons and Fleischmann of fraud, or of purposely misleading others trying to replicate their results. To my knowledge, there is absolutely no truth to these innuendoes. As Pons and Fleischmann stated early on, and history has verified, their experiments were not reproducible due to unidentified factors in the materials science of the electrodes. Generally, when an electrode “worked,” all from that batch of Pd did so, and conversely if it did not work, none did. (This problem is now generally thought to be associated with micro cracking that occurs in some electrode materials during the expansion and stresses caused by loading. Thus, in my own research I have tried to avoid this problem by the use of thin sputtered films for the electrodes. These films have more elasticity so that the tendency to crack during loading is reduced.) While Pons/Fleischmann explained this problem at various meetings, many refused to accept their explanation, claiming something was being withheld. As time passed, it became clear that Pons/Fleischmann had indeed provided all of the factual information known about the electrode problem. However, they were significantly hampered in “openness” in some aspects of the research by overzealous sponsors requesting tight reigns on intellectual property, a situation that remains all too common in the company-dominated field of CF.

Others have somehow tried to associate fraud with the initial introduction of CF via a public news announcement. That view is that the news announcement was purposely distorted for personal gain. To my knowledge, that is simply not true- The information provided was a factual presentation of the data as these researches saw it at the time. However, the news release approach is a most serious break from traditional behavior in any scientific field. In retrospect, it must be noted that the pressures on Pons/Fleischmann at that time were tremendous. Indeed, I would suspect that others who have been so vocally critical of them may have turned to this route if they were placed in a similar situation. Still, the disclosure of scientific results via new releases is certainly to be avoided if at all humanly possible. Such actions are certain to create a “backlash” in the community that interferes with (or may even stop) the scientific search for truth. Everything from the scientific community’s evaluation of the basic science to funding for the field can become grossly distorted by the emotions set in force. Indeed, in the case of CF, the resulting “backlash” soon isolated the field from the mainstream scientific community.”

In the last section, entitled “Conclusion” Milye wrote: “With the growing pressures on researchers in modern society, we must work hard to preserve an atmosphere where the primary objective is to “seek the truth”. Clearly, the turmoil and divisions in the CF area created by persons both within and without the field confused and retarded this search for truth. With human nature being as it is, it is hard to believe that we can prevent a repeat of the CF episode in future areas where high stakes of money and prestige are involved. The education of upcoming scientists, journalists, research managers, etc. in scientific ethics is the best defense. Indeed, my only formal training in the area was a one-hour course on “professional ethics” required of all science/engineering students when I was a senior in college. “

37) Coulomb barrier lowering?

Ludwik Kowalski (January 14, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

How can two deuterons fuse without having sufficiently high kinetic energy to overcome repulsion? By the tunneling "under the barrier." The theory of than QM effect is well developed and its predictions, for D+D fusion in plasma, agree with experimental data at all kinetic energies above 10,000 eV. But what about even lower energies in solid substances, for example, at 0.05 eV, which is typical? At such energies, according to theoretical calculations, the probability of fusion is about 50 orders of magnitude lower that what would be consistent with the amounts of excess heat. Therefore, argue the critics of "cold fusion," what is observed is not ordinary nuclear fusion. Those who believe in reality of "cold fusion" accept the criticism but claim that Coulomb barrier is somehow lowered in certain chemical environments. But they do not know why this happens.

According to conventional tunneling theory the probabilities of nuclear reactions should not be influenced by changes in chemical arrangements of atomic nuclei in solids. But a study conducted by Kosagi, in 1998, contradicted this expectation, as described by Storms (see my item # 32). Kasagi confirmed that the theoretical predictions of D+D fusion probabilities agree with experimental data at kinetic energies above 10,000 eV. At lower energies, however, the measured probabilities (in the PdO solid) were found to be higher that theoretically predicted. At 2,500 eV, for example, the experimental probabilities (technically expressed in the form of cross sections) are fifty times higher than theoretically predicted. The discrepancy grows very rapidly when kinetic energies become lower.

Unfortunately, no experimental data on D+D fusion probabilities are available below 2,500 eV. Is it reasonable to think that in going from that kinetic energy to 0.05 eV the discrepancy may become much higher, especially when the PdO is replaced by a material able to generate excess heat? Here is how all this was described by Storms (in a review rejected by four journals):

"Enhanced Cross Section: The observations imply a higher than expected cross-section for fusion at very low energy. To explore this possibility, Kasagi et al.[162] bombarded various metals and compounds with deuterons of various energies down to 2.5 keV and measured how much enhancement was produced in the reaction D(d,p)T, as shown in Figure 9. Apparently, an increase in cross-section does occur at low energy when the reaction occurs in a solid, in contrast to when the reaction is initiated in a plasma. In addition, enhancement is greater in PdO than in a number of pure elements[163], thereby showing that the nature of the chemical environment is important. Because the solids were not expected to be nuclear-active under the conditions of the study, the measured cross-sections represent only a lower limit for what might be possible when the "correct" solid is used. Other studies indicate that the branching ratio between tritium and neutron production might also change at low energy.[164-166] Once these possibilities are acknowledged, the next problem is to propose how the cross-sections might be increased at low energy by the surrounding atoms."

This kind of reasoning can be used to suggest experiments designed to probe the region of lower energies. It should be used to promote new investigations of the tunneling effect at very low kinetic energies. I see nothing unusual in such constructive speculations. Why did the editor of Review of Modern Physics label Storms' article as pathological science (see item #33)?

38) On production of tritium

Ludwik Kowalski (January, 22, 2003)
Montclair State University
Upper Montclair, NJ 07043

Return to the clickable list of items

I have just read “Tritium Production from Low Voltage Deuterium Discharge on Palladium and Other Metals” (by Claytor et al.) and am impressed. Why did this paper appear in the marginal, “Journal of New Energy” (vol 1, #1, 1996, p111-118) rather than, for example, in Physical Review? Did a main-stream journal editor reject the paper as fraudulent science? Would the paper be rejected today?

You may recall my translation of a Russian paper (item #13) describing nuclear reactions occurring in a gas discharge chamber. The paper of T.N. Claytor, D.D. Jackson and D.G. Tuggle is similar, except it focuses on one aspect only -- production of the radioactive material, tritum. The authors are researchers from Los Alamos National Laboratory. (It is no longer a secret that tritium is an explosive material of a hydrogen bomb and that LANL is a place focusing on the design of nuclear weapons. Where else can you find better expertise for dealing with tritium then in that laboratory?)

The gas discharge apparatus consisted of a very thin Pd wire (diameter of 100-250 microns), used as a cathode, and a flat Pd plate, used as an anode. The gap between the wire, perpendicular to the plate, and the plate was several millimeters. The deuterium gas pressure was 300 torr. To prevent excessive heating short pulses of current (10 microseconds) were applied at the rate of 20 per second (2000 volts, 3 to 5 A). Tritium was produced when the wire was exposed to discharge plasma; typical accumulation rates were between 0.1 and 0.2 nCi/hr. In one experiment 102 nCi was produced in about 300 hrs. The article describes numerous precautions, and tests conducted, to make sure that observed generation of tritium was real (rather than due to contamination).

What can be a better proof that a nuclear process can take place at nearly room temperatures? Journal of New Energy, in which the article was published, is edited by Hal Fox. I met Hal in Salt Lake City and he showed me his laboratory. But this deserves a separate item.

39) Other strong cases

Ludwik Kowalski (January, 24, 2003)
Montclair State University
Upper Montclair, NJ 07043

Return to the clickable list of items

You may recall my translation of a Russian paper (item #13) describing nuclear reactions occurring in a gas discharge chamber. The most convincing argument of nuclear processes, as far as I am concerned, was the discovery of iron whose isotopic isotopic composition was highly abnormal. I am now reading a summary of a Japanese paper reporting similar observations. The title of the paper is "**Changes in Isotopic Distribution of the Elements on Palladium Cathode after Electrolysis in D_2O Solution**;" the first (one out of nine) authors is T. Mizuno.

The isotopic composition of Cr, collected from the surface of a palladium electrode, after it was used to produce excess heat, was unnatural, as shown below:

A --> 50 52 53 54

from Pd --> 14% 51% 2.4% 11%
natural --> 4.3% 84% 9.5% 2.4%

According to the summary "essentially the same phenomenon was confirmed eight times, with high reproducibility, at the cathodic current density of about 0.2 A/cm^2." How can the isotopic composition be changed without a nuclear process? These finding were presented in 1997, as paper #71198, at IECEC. I do not know what the IECEC stands for, probably for a conference.

In the paper #97373, entitled: "**Nuclear Transmutations Induced by Light water Electrolysis with Gold Electrodes**," presented at the same conference, the authors reported finding iron of highly unnatural isotopic composition. Their 50 % abundance of ^{57}Fe (instead of natural 2.2%) was essentially the same as that reported by Karabut (see item #13). Note that Karabut analyzed products accumulated on the palladium cathode in the deuterium discharge chamber while the Japanese were studying the electrolysis of ordinary water. According to the summary "the amount of Fe reached some 10 micrograms after the electrolysis for 20-30 days."
The authors' affiliations are:

a) Dept. of Nuclear Engr., Hokkaido University, Saporo, Japan.
b) Catalysis Res. Center, Hokkaido University, Saporo, Japan.
b) Hakadate Natl. Coll. Technol, Hakadate, Japan.

How would a pathological skeptic react to such data? Here are my guesses:

a) The data might have been invented to deceive (a case of fraud).
b) The authors do not know how to measure isotopic compositions.
c) Somebody “spiked” their cathode, just for the fun of it.
d) The data are wrong because they conflict with accepted theories.
f) The data should be ignored because they are pseudo scientific.

40) A Cold Fusion Essay

Ludwik Kowalski (January, 22, 2003)
Montclair State University
Upper Montclair, NJ 07043

Return to the clickable list of items

1) What follows is a lecture outline for the second semester of General Physics. My goal is to focus on conceptual aspects of CF rather than on its historical and social aspects. I think that trying to avoid the phrase "cold fusion" is like trying not to use the noun "heat." Cold fusion is not the best name for the phenomenon of LENR (low energy nuclear reactions) but it is the name under which it was introduced, and under which it is remembered by most people. Some prefer CANR (chemically activated nuclear reactions), others prefer AEP (anomalous energy) phenomenon. These are more descriptive names but CF is likely to be used most frequently.

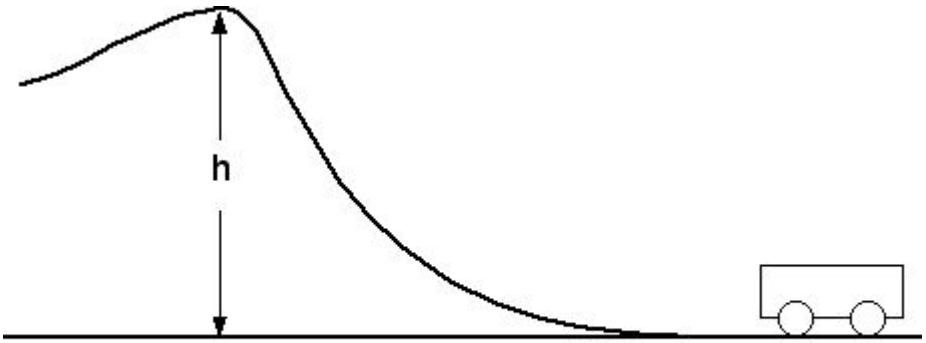

Figure 1

2) The term fusion will be introduced as an act of a perfectly inelastic collision between two atomic nuclei moving toward each other. The nuclei will be visualized as uniformly charged spheres. This is a mental picture, and a mathematical model, responsible for naming the phenomenon CF. What is necessary to make two positively charged nuclei fuse like two drops of water? They repel each other with Coulomb force and that force must be overcome by the cohesive nuclear force. The nuclear force is known to be negligibly small (with respect to repulsion) when the gap between the spheres is about 2 F ($2*10^{-15}$ m) but it becomes dominant at shorter distances.

3) After discussing nuclear fusion in terms of forces I will start describing it in terms of energies. To facilitate the transition I will refer to a familiar example of a frictionless cart pushed along a horizontal road toward a hill, as illustrated in Figure 1. Yes, the size of the cart is exaggerated. Will the cart go over the hill (this represents fusion) or will it start rolling back, after reaching some elevation? Students know that the answer depends on the initial kinetic energy of the cart, KEi. The car will go over the hill when KEi>PEt, where PEt=m*g*h is the potential energy at the top of the hill. Otherwise it will roll back without reaching the top. The energy diagram to discuss nuclear fusion is shown in Figure 2.

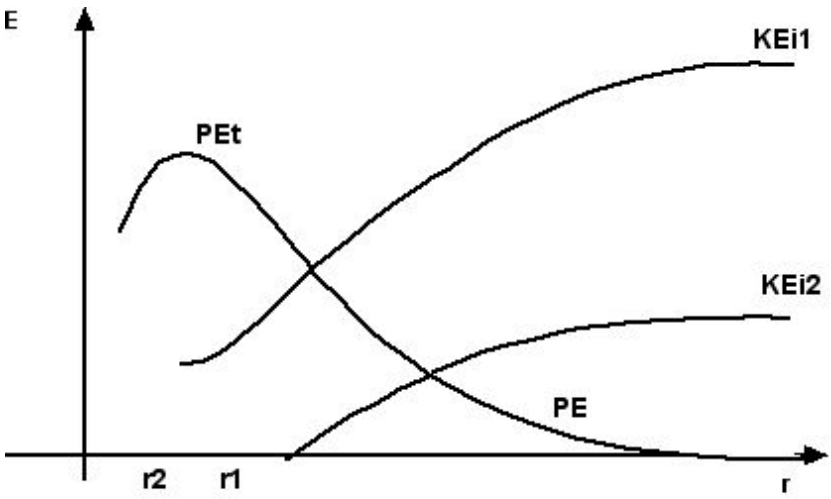

Figure 2

The horizontal axis of that figure, r, is for distances between the centers of the spheres; the vertical axis. E, is for energies, both potential and kinetic. The line with a maximum shows how the potential energy, PE, depends on the distance r. By convention, potential energy associated with repulsive (electric) forces is positive while the PE associated with attractive (nuclear) forces is negative. Repulsion is dominant at $r>r_1$ while nuclear forces are dominant when $r<r_2$. The maximum potential energy occurs between r_1 and r_2. The lines labeled KEi1 and KEi2 show how kinetic energies change with r, in two different cases. In one case the initial kinetic energy is smaller than the maximum potential energy; in another it is larger. The total energy PE+KE must remain constant at any r>r2 (before fusion), as for the cart in Figure 1. This explains why fission is energetically forbidden unless KEi>PEt.

The maximum potential energy, PEt is often referred to as the Coulomb barrier. It turns out that for two deuterons the PEt is slightly lower than 1 MeV ($1.6*10^{-13}$ J) while r2 and r1 are about 1 F and 2 F, respectively. The non-sphericity of deuterons, and the centrifugal potential energies, can be ignored in a preliminary, semi-qualitative, description.

4) After introducing the energy diagram I will digress toward two ways of increasing the initial kinetic energies (to satisfy the KEi>PEt condition). The first way is to increase the gas temperature and the second is to accelerate ions, for example, by using an electrostatic generator. Referring to kinetic theory of gasses, and assuming that the absolute temperature is ten billion K, I will show that only a very small fraction of particles has enough kinetic energy to exceed 1 MeV. Electric accelerators will be mentioned because they are often used to study probabilities of fusion at different kinetic energies. These experiments showed that fusion occasionally occurs even when KEi is less than the Coulomb barrier, PEt. This is schematically illustrated in Figure 3.

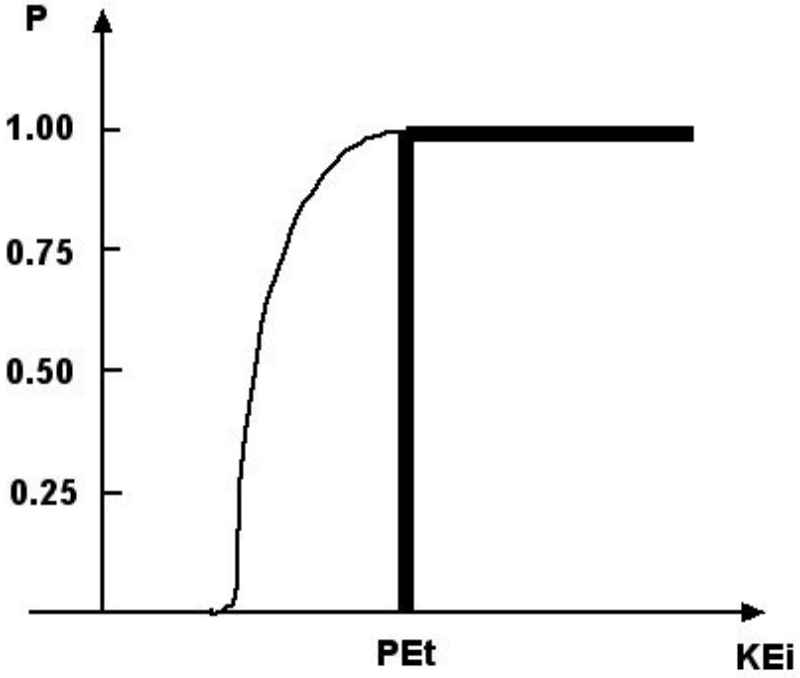

Figure 3

The thick line, in that figure, corresponds to predictions of classical theory while the thin line corresponds to experimental data. Our classical theory predicts that the probability of fusion, p, changes suddenly from zero to one at KEi=PEt. The experimental data, on the other hand, show that the transition is gradual (the energy scale strongly expanded in Figure 3).

5) I will tell students that in physics, unlike in mathematics, theories are validated by experimental data. The data show that the familiar classical model, highly reliable in macroscopic physics, is no longer a good description of what actually happens in a submicroscopic process. This observation led, in the 1920's, to the development of a new theory known as quantum mechanics, QM. That theory is in good agreement with experimental data for kinetic energies above 10,000 eV. For any given KEi the theory can be used to calculate the probability of fusion, p. The value p=0.1, for example, would indicate that, on the average, only one out of ten collisions result in fusion while the rest result in rebounding (scattering).

Referring back to Figure 1 I will ask: "what is needed to allow the cart to pass to the other side of the hill when KEi is smaller than PEt?" And I will wait till the word "tunnel" is mentioned. The QM under-barrier fusion is often referred to as a tunneling effect. The new theory can be naively interpreted by saying that p is a probability of "finding a tunnel." Detailed calculations show that p decreases very rapidly when D=PEt-KEi becomes larger and larger. The consequence of this is that fusion at ordinary temperatures should be extremely rare, p is much smaller than 10^{-50}. In other words, according to the tunneling theory, fusion at room temperature should be practically impossible. That is why most physicists were skeptical when a claim was made, in 1989, that experimental data contradict this prediction. The controversy, as far as numbers are concerned, has to do with the probability of fusion. Is it smaller than 10^{-50} or is the order of magnitude closer to 10^{-20}? Note that $p=10^{-20}$ still means that only one out of 10^{20} collisions results in a nuclear fusion event. But considering how many atoms move toward each other at any given moment, and the amount of energy released (for example 10 MeV per event), the $p=10^{-20}$ is large enough to produce detectable heat.

Criticizing cold fusion experiments was easy in the first two or three years after its premature announcement because the phenomenon turned out to be more complex than anticipated. The numerous factors influencing outcomes of experiments, such as the role of impurities, were not known and "failures to confirm" were not rare. But the situation changed and experimental data are said to be much more reproducible today. The consensus of scientists working in the field of cold fusion is that nuclear processes do occur with measurable probabilities. They claim that the QM tunneling theory is no longer applicable at very low kinetic energies and when ions are oscillating about their equilibrium on metallic surfaces. On the other hand, a generally accepted theory of cold fusion does not exist.

It is important to emphasize that the tunneling theory has not been developed to deal with kinetic energies as low as 0.05 eV (room temperatures). An attempt to verify the tunneling theory, at very low kinetic energies, was made in 1998 (Kasagi et al.). By using beams of accelerated particles the authors showed that theoretical predictions agree with experimental data at KEi>10,000 eV but not below that limit. At 2,500 eV, for example, the experimentally measured p was found to be over fifty times higher than what was predicted. The main argument against the idea of cold fusion was based on the assumption that the tunneling theory, and its parameters, are valid down to kinetic energies as small as 0.05 eV?

What should scientists do when experimental data seem to disagree with a model in an area in which the model has never been tested? The first thing to do is to make sure that data are reproducible, the second is to agree on the interpretation of data. For example, if excess heat is confirmed then what evidence do we have that it is due to nuclear reactions? If alpha particles, or tritium, are observed then we must be sure that this is not due to a contamination. And the third thing to do is to reanalyze and to improve the theory. A theory which disagrees with confirmed and reconfirmed facts should be declared to inapplicable.

6) The overall (scientific and social) picture of the situation in the field of cold fusion can be summarized as follows.

a) The scientific community is divided into supporters and skeptics.

b) Skeptics, representing mainstream science, claim that supporters are not true scientists. The skeptics refuse to conduct cold fusion experiments.

c) Supporters continue experimenting and discussing significance of their findings. Evidence backing reality of nuclear processes influenced by changes in chemical (atomic) arrangements is mounting. But most of that evidence is not described in mainstream journals.

d) Conducting research in the area of cold fusion is a “risky business” for young scientists. This is caused by practically non-existing financial support, for example, from NSF or DOE, and by unjustified accusations that anything connected with cold fusion is “pathological science”. Most scientists conducting cold fusion research are at least sixty years old.

e) In my opinion, the time is ripe to conduct an objective evaluation of what has been accomplished in the last ten years, and to either confirm or deny that the area is unscientific. If the interdisciplinary cold fusion field is found to be scientific then research in it should be encouraged, as in any other area.

41) A message from a friend

Ludwik Kowalski (kowalskil@mail.montclair.edu)
Montclair State University, Upper Montclair, NJ 07043

Return to the clickable list of items

An Internet friend, physics teacher an electrical engineer and an observer of cold fusion, sent me a message about that field last night. I think his wise comments and quotations are worth adding as an item to my list. He wrote:

“ I'm still running the forum for Cold Fusion and physics anomalies, "vortex-L." A couple of the CF scientists are current subscribers, as are the ones running the lenr-canr.org site. See

http://amasci.com/weird/wvort.html

The biggest issue I have with the CF controversy is that each experiment supposedly takes upwards of six months, since it takes that long to build up sufficient protons in the palladium electrodes. Simply designing the appropriate equipment take more months. Yet the "ERAB" report condemning Cold Fusion was submitted only 8 months after the very first Pons-Fleischmann announcement. Cold fusion supporters label this historical
event as "the rush to judgment," and point out that the CF claims couldn't possibly have been given honest testing. I can't see how it could be anything else. WHETHER OR NOT THE "CF" EFFECT EXISTS, the controversy appears to be a classic example of intellectual suppression.

I like Arthur C. Clarke's prediction, that Drs. Pons and Fleischmann will be
the only scientists in history to win both the Ignoble and the Nobel
prizes. Take a look at Julian Schwinger's [Nobel laureate] talk on CF:

http://www.lenr-canr.org/acrobat/SchwingerJcoldfusiona.pdf

(Unfortunately Dr. Schwinger is no longer around to defend CF against disbelievers.)

> In fact your old message will be reposted there soon. I wander what you think about cold fusion now? Your comments and observations will be appreciated.

If 500 researchers fail to replicate, while 5 researchers claim success, does this proves that the claimed phenomenon doesn't exist? When doing science, majority rules? Consensus leads the day? The real world doesn't work like that. Yes, maybe those 5 researchers made mistakes, so that their success was an artifact. But maybe the 5 were right, while the 500 unsuccessful attempts only prove that replication is extremely difficult. We supposedly have ways to cut through to the truth, but they cannot work if the field is filled with covert irrationality driven by hidden emotions, or by huge glaring conflicts of interest. Fourteen years later the heat has died down and perhaps reality can finally be seen behind the noise caused by the CF-bashers and CF-lovers.

Ed Storms claims that CF is now easily replicated (well, easy for those with the skills and equipment.) He gets anomalous heat and and tritium production but not the neutron production which is expected from hot-fusion reaction paths (see Schwinger's comments on neutrons in his paper linked above). It would be very interesting if groups outside the current CF community would agree to look into this. Yet there's still the chance that such an attempt, if successful, would do nothing but ruin careers. After all, attaining success at "cold fusion" experiments supposedly DOESN'T add to the body of evidence supporting the existence of CF, instead it just proves that the experimenter is at best mistaken, or at worst has changed sides and gone to join all the other "loonies;" those professional scientists who claim repeated

success. If CF is a genuine phenomenon, such a controversy is certainly not the first of its kind...

1) "If I want to stop a research program I can always do it by getting a few experts to sit in on the subject, because they know right away that it was a fool thing to try in the first place." ...- Charles Kettering, GM

2) "...By far the most usual way of handling phenomena so novel that they would make for a serious rearrangement of our preconceptions is to ignore them altogether, or to abuse those who bear witness for them." - William James

3) "When adults first become conscious of something new, they usually either attack or try to escape from it... Attack includes such mild forms as ridicule, and escape includes merely putting out of mind." - W. I. Beveridge

4) "A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die and a new generation grows up that is familiar with it." - M. Planck

5) "Theories have four stages of acceptance: i) this is worthless nonsense; ii) this is an interesting, but perverse, point of view; iii) this is true, but quite unimportant; iv) I always said so." -J.B.S. Haldane, 1963

6) "New and stirring things are belittled because if they are not belittled, the humiliating question arises, 'Why then are you not taking part in them?' " - H. G. Wells

7) "The mind likes a strange idea as little as the body likes a strange protein and resists it with similar energy. It would not perhaps be too fanciful to say that a new idea is the most quickly acting antigen known to science." - Wilfred Trotter, 1941

8) "Be not astonished at new ideas; for it is well known to you that a thing does not therefore cease to be true because it is not accepted by many." - Spinoza

9) "If we watch ourselves honestly we shall often find that we have begun to argue against a new idea even before it has been completely stated." - Wilfred Trotter

10) And most frightening, a quote from a paragraph about instances of suppression in the history of science: "Many [genuine] discoveries must have been stillborn or smothered at birth. We know only those which survived." - W. I. Beveridge, THE ART OF SCI. INVESTIGATION, 1950"

42) Four Points of View

Ludwik Kowalski (February 9, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ

Return to the clickable list of items

1) In criticizing somebody who made an unreasonable theoretical claim about capacitors (on the Phys-L list) a physics teacher wrote:

> . . . It became transparently obvious pretty early on that you have
> little or no interest in being educated and almost no ability to
> listen to what others are saying. You seem to have developed an
> impermeable shield to criticism that allows you to discount it as
> misguided when patiently offered and malevolent when it (inevitably)
> becomes more blunt. This is a characteristic trait, as Bob mentioned
> in an earlier post, of practitioners of pseudoscience. .....In any event,
> you shouldn't expect anyone to show the least interest in a theory
> that predicts something VERY different unless you come armed
> with some convincing and reproducible experimental evidence and
> can show how your theory squares with the current well-verified
> predictions in most every other situation. . .

A message addressed to a cold fusion researcher would also emphasize the need for reproducible experimental evidence. But that evidence would be used to validate experiments rather than to validate a theory. Why? Because no acceptable theory dealing with chemically activated nuclear reactions emerged. One of the blunders of Fleischmann and Pons was to name the strange phenomenon cold fusion. The nuclear fusion theory exists but it seem to have nothing to do with (presumably discovered) new kind of nuclear reactions.

2) In a private message to me an active cold fusion researcher wrote:

>Today a new physical phenomenon must to be based on a
> theoretical model. I am trying to develop a model focusing on a
> possible mechanism of a nuclear reaction trigger. It is a new
> area of science -- physics of optically active solid media in the
> energy range of 1 - 2 keV. But experimental data are hard to get.

Who can deny that a theoretical model is desirable? Who can deny that a researcher armed with a model is likely to be more effective than those who are not? But saying that experimental facts can not be taken seriously unless they are described by a theoretical model is an exaggeration. Most experimentalists are not well equipped to develop sophisticated theoretical models. Physics is an experimental science. To me this implies that, in the final analysis, experiments are validated by other experiments, not by theories.

3) This brings me back to a Phys-L list message posted on December 14, 2002. My slightly edited reply to the anonymous friend was in capital letters.

Ludwik:
As you state repeatedly, the whole atmosphere around CF has been filled with poisonous material, some valid and some

emotional. One must be very careful, on entry into such an atmosphere, to be protected by a useful theoretical proposal or at least a plausible explanation that can be subjected to experimental tests. On the basic level there are two obvious questions:(1) How could hydrogen atoms fuse at such a low temperature?(2) If they do fuse, how is the energy released (if not in gamma rays, then how) i.e. what reaction occurred?

If one has no proposed answer or proposed experiment to get an answer, then one is in a state of massive weakness. Your message seems to be that there is new evidence for an interesting mystery, and the early workers were not fairly treated. The author of such a message will be classified as an apologist or defender, no matter how he qualifies such words. If, however, he has a plausible proposal, it could possibly be different. I infer that the major skepticism in the mainstream nuclear science community stems from the silence on the basic two questions above. Such skepticism seems to me to be justified until something reasonable is proposed or, better yet, demonstrated. Until then, essentially all responses will be "impurities or errors".

BOTH QUESTIONS CAN ONLY BE ASKED IF A CLAIM IS MADE THAT FUSION TAKES PLACE. IT WAS FOOLISH TO MAKE SUCH A CLAIM IN 1989 AND IT IS FOOLISH TO MAKE IT TODAY. THAT IS WHY NAMING THE EFFECT "COLD FUSION" WAS HIGHLY INAPPROPRIATE.

THE CLAIMS, AS FAR AS I CAN TELL, ARE:

A) EXCESSIVE (UNACCOUNTABLE) HEAT IS GENERATED IN SOME EXPERIMENTS. B) SOME NUCLEAR PROCESSES ARE TAKING PLACE WHEN EXCESS HEAT IS GENERATED.

YES, THE ONLY WAY TO VALIDATE SUCH CLAIMS IS TO PERFORM EXPERIMENTS. IF IT WERE UP TO ME I WOULD ASK PHYSICISTS TO FOCUS ON A SINGLE ASPECT OF THE SECOND CLAIM, FOR EXAMPLE, EMISSION OF ALPHA PARTICLES. INSTRUMENTS FOR CONTRADICTING OR CONFIRMING EMISSION OF ~14 MEV ALPHA PARTICLES AND ~3 MEV PROTONS (PRESUMABLY OBSERVED BY MANY) ARE WIDELY AVAILABLE. IN OTHER WORDS, THEY WOULD BE ASKED TO VERIFY WHAT IS EASY, AND WHAT COULD BECOME A HIGHLY SIGNIFICANT INDICATOR OF SOMETHING NEW AND INTERESTING. CONFIRMATIONS WOULD START THE USUAL PROCESS OF GOING FROM KNOWN TO UNKNOWN, FROM SIMPLE TO MORE COMPLEX, FROM EXPERIMENTAL FACTS TO THEORIES, ETC.

A LACK OF CONFIRMATION WOULD INDICATE THAT THOSE WHO MADE CLAIMS WERE WRONG. I WOULD THEN ASK PHYSICISTS TO FOCUS ON ANOTHER, PRESUMABLY OFTEN OBSERVED, "NUCLEAR SIGNATURE" AND TRY TO VALIDATE OR CONTRADICT IT. THREE FAILURES TO CONFIRM WOULD PROBABLY BE SUFFICIENT TO SAY THAT EXCESS HEAT, IF ANY, HAS NO NUCLEAR ORIGIN. TROUBLES BEGAN WHEN CHEMISTS, UNFAMILIAR WITH NUCLEAR PHYSICS, STARTED TO MAKE PRONOUNCEMENTS ABOUT IT, AND WHEN PHYSICISTS, UNFAMILIAR WITH CHEMISTRY, ENTERED THE COMPLEX FIELD OF ELECTROCHEMISTRY.

I visited the anonymous friend recently and we talked about cold fusion again. I described a hypothetical scenario in which a totally unexplained phenomenon is observed. Thorium nitrate (radioactive salt) is dissolved in pure water inside a sealed metallic container. The container plus solution are initially radioactive, as measured by a Geiger counter, or by a sophisticated Ge(Li) gamma ray spectrometer. But it is no longer radioactive after the experiment. A scientist who performed the experiment wants to publish the observation in a scientific journal. If you were the editor of that journal, I asked, would you allow the submitted paper to be published? The answer was “no I would not publish it.”

Then I said, suppose that the researcher takes you to his lab and performs the experiment in front of you. He then offers you a chance to set up a similar experiment from scratch and to perform it by yourself, perhaps using your own instruments with your own assistants. You do all this and you are convinced that ‘this incredible claim” seems to be real. Would you now allow the paper to be published? His answer was negative; he believes that experimental evidence, no matter how strong, should not be published, unless some kind of simple ‘theory” is provided. The issue of conservation of mass and energy must be addressed by the author.

I said that mainstream science publications, for example, in astronomy, are often “purely experimental.” Experimentalist

discover facts, theoretically inclined scientists try to explain them in terms of what is already known or to develop new models of reality. Why should a cold fusion publication be treated differently in that respect? I also reminded him about Pierre Curie's 1903 paper about the unexplained heat coming out of radium. It was a purely experimental paper; the only "theoretical" comment was that it must be something totally new. Yes, answered my friend, but this was one hundred years ago. What was acceptable then is no longer acceptable in nuclear science today.

Yes, the first discovery of excess heat was made exactly one hundred years ago. It would be nice if more recent "excess heat" claims were given a chance to be examined in 2003.

4) Let me end this item with an interesting observation made a biochemist, in a private conversation, "Trying to publish something in a scientific journal means convincing the editor, and reviewers, that the expressed ideas fit the existing paradigm. That is why those who discover unexpected things often encounter difficulties in trying to publish articles. But trying to patent an invention is just the opposite. The patent bureau wants ideas which are really new; something based on what is already known is not acceptable."

This is an interesting observation, except for one thing. Is it true that a special order has been given, by the US government to the Patent Office, not to accept patents based on cold fusion ideas? I heard about this from two people. I also heard that the legal situation changed very recently; cold fusion patents rejected in the past are ordered to be reevaluated. I would appreciate it if somebody familiar with patent issues (in the area of cold fusion) could describe the situation briefly. Please e-mail this description to me <kowalskil@mail.montclair.edu>and I will append it as an item on my web site.

43) An Embarrassing Editorial

Ludwik Kowalski (February 2003)
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

In browsing the Internet with Google I found a letter to the editor of Nature from my classmate, M. Gryzinski. We (at the Polytechnic Institute of Warsaw) were proud of him when he constructed a Frank-Hertz tube and showed us the peaks. I haven't heard from him since our graduation in 1957 and was curious to find out what he wrote. Less than one month after the announcement of cold fusion he was referring to his earlier theoretical paper on how the Coulomb barrier between two atoms in H_2 could be lowered by a trapped electron. That was in Nature, vol. 338, April 27, 1989.

Looking through other issues of Nature I found David Lindley's editorial (volume 344, March 29, 1990) entitled "The Embarrassment of Cold Fusion." This is an example of a very negative evaluation of the field, one year after Fleischmann and Pons announced their discovery, and several months after the ERAB report. The author was the associate editor of Nature. I think that his article, see below, is worth adding to my collage.

* * * * * * * * * * * * * * *

Those readers who consider that this journal has published too much on cold fusion' should be grateful for what they have been spared.

In the year since Stanley Pons and Martin Fleischmann made their famous announcement at a press conference at the University of Utah, we have received a barely imaginable quantity of letters— most of them respectably typed, one or two handwritten entirely in capital letters —attesting to remarkable latent powers of creative thinking by scientists around the world. For only a few of these offerings was it. thought necessary to consult expert reviewers; fewer still survived that scrutiny.

Of the fraction of papers submitted that have thus reached print, the account appearing this week (see page 401) is of special significance. Michael Salamon and his colleagues, like the teams from Yale University and Brookhaven Laboratory, from the California Institute of Technology, and from the UK Atomic Energy Authority Laboratory at Harwell, have searched for nuclear emissions (neutrons, gamma-rays, electrons and protons) from cold fusion cells, and found nothing. The difference is that Salamon works at the University of Utah, and the cold fusion cells he examined were in the laboratory of Pons and Fleischmann.

This is not quite the same as saying that what Salamon et al. Iooked at were Pons and Fleischmann's cold fusion cells. As the article makes clear, Pons will not concede that any of the electrolytic cells were, at the time they were being examined, in fact producing anomalous heat. There was a two-hour period when, according to Pons, a cell under examination was producing excess heat -- but at that time the detectors and computers of Salamon and his colleagues were not working, having been put out of action by a power cut.

To this, Salamon et al. provide a clever response. Any neutrons emitted by the working cold fusion cell would have created some secondary radioactivity in the neutron detector, which should have been measurable once the equipment was switched on again after the power loss. But no such secondary activity was found. which allows Salamon et al. to conclude that no conventional fusion reactions could have produced the claimed excess heat.

The tidy summary of their paper is therefore that during a five-week period which came some time after the press announcement of Pons and Fleischmann on 23 March last year, cold fusion cells which may or may not have been producing excess heat certainly produced no anomalous nuclear emissions.

In the light of the known history of cold fusion, one has to ask whether this news will change the terms of the debate.

During the past year, the original claims of Pons and Fleischmann have diminished; the experimental evidence has been subtracted from not added to. In their 'preliminary note' (J. electroanalyt. Chem. 261, 301-308;1989 and erratum 263, 187 -188; 1989) Pons and Fleischmann said that they had found, as well as excess heat, production of tritium in the cell, and the emission of neutrons, detected by characteristic secondary gamma-rays from the surrounding water-bath. But the tritium concentration in a working cell turned out to be only three and a half times greater than that in the original stock of heavy water. Critics were quick to point out that such an increase is consistent with a recognized difference in the electrolysis rate of deuterium and tritium on account of their different masses.

Later, Petrasso (see Nature 339, 183; 1989) argued that the gamma-ray signals presented by Pons and Fleischmann as evidence of neutron emission had the wrong characteristics to be genuine detections, and were more likely to be instrumental artifacts.

This left only the claims of excess heat, which were themselves challenged at the' Baltimore meeting of the American Physical Society (see Nature 339, 4;1989)

Pons and Fleischmann must be given credit for declaring from the outset that the amount of excess heat they saw was too great, by orders of magnitude, to be consistent even with the levels of nuclear emission that they described in their preliminary note.

Supporters of heat production by cold fusion have always said that some new physical process, by which deuterons can fuse in secret without giving off telltale nuclear byproducts, was indicated by their results.

Thus arises the schism that separates those who believe in cold fusion from those who put the whole episode down to wishful thinking. On one side, nonbelievers see the negative results of Salamon et al. as incontrovertible proof that nothing unusual is happening; on the other, believers take the same results as affirmation that cold fusion indeed demands new physics, which they knew already.

The two sides are separated by a matter of faith, not one of science.

Efforts to bridge this divide have been made all the more difficult by the unceasing refusal of Pons and Fleischmann to say clearly and fully what their experimental evidence for cold fusion is. In the wake of their preliminary note and its published errata (which were themselves an extended version of a preliminary list of errata handed out as a photocopied sheet with the 10 April 1989 copy of Journal of Electroanalytical Chemistry), there came rumors (subsequently and vehemently denied at the Los Angeles meeting of the Electrochemical Society on 8 May last year) of heat generation by cells containing ordinary water rather than heavy water, and of the production of 'He in significant amounts. The discovery of ^{4}He in the gases coming from a cold fusion cell was briefly trumpeted as a demonstration that deuterons absorbed into the palladium electrode were indeed fusing, but by a reaction that produced 4He and a gamma ray rather than tritium and proton or ^{3}He and a neutron, as conventional nuclear physics would have it.

Inconveniently, however, materials scientists pointed out that if helium had been formed in the palladium electrode, it would have stayed there; the correct test would have been to look for helium in the palladium itself, not in the gases evolved by the cell. But because Pons and Fleischmann had given out the suggestion about helium production in their usual teasing and informal way, it could be retracted without much pain on their parts. During April and May last year, there were constant assurances that a detailed account of their experimental methods and results was in preparation, would be properly submitted to a scientific journal, and would appear during the summer, or in the autumn -- or perhaps a little later.

But what was reprehensible a year ago has now become absurd.

Still there are whispers of a hundred-page manuscript, replete with facts and figures, which the world will soon see. Most of the world, sadly for Pons and Fleischmann, is unlikely to care, except perhaps out of historical curiosity and a desire that the tale be neatly ended.

The waxing and waning of these various pieces of ancillary evidence, not to mention the sporadic nature of the successes achieved even by expert cold fusion researchers, was a wonderful liberation to those who rummaged through their undergraduate physics textbooks in search of forgotten phenomena that could be adapted into theories of cold fusion. It was a boon too that solid-state physics and quantum mechanics conspire to offer such a variety of unexpected and counterintuitive effects to the eager inquirer.

If the ideas submitted to this journal are a representative sample, theories of cold fusion generally have the same logical structure as the assertion: "If we had some ham, we could make a ham sandwich, assuming there's some bread handy". Starting from some bona fide physical effect, one argues that if it were many orders of magnitude more important than it actually is, cold fusion would be possible; left unspoken is the assumption that the effect in question is of some relevance in palladium saturated with hydrogen.

In the proliferation of theoretical proposals, there were surprisingly few basic ideas. A number of early suggestions referred to the Oppenheimer-Phillips effect: at very low energies, two deuterons in close proximity tend to orientate themselves so that their constituent neutrons approach each other and keep the protons apart, which enhances the fusion rate because it permits the neutrons to interact while minimizing the electrostatic repulsion of the protons.

Explanations of this sort illustrate a common feature of cold fusion theories. The discrepancy between the standard fusion rate and what was needed to generate the heat seen by Pons and Fleischmann amounts to some 60 orders of magnitude. and the Oppenheimer-Phillips enhancement is a matter of ten per cent or so; nevertheless the reader was invited to agree that things were moving in the right direction, and accept that a bit of numerical fine-tuning would be needed to take care of the details.

A somewhat more sophisticated clutch of ideas emerged as people latched on to the idea of effective masses. Two deuterons bound together in a molecule have a tiny but calculable chance of fusing and if, as a thought-experiment, the mass of the orbiting electrons is increased, the molecule becomes more tightly bound and physically smaller, and the fusion rate rises. It was then noted that electrons in palladium can have effective masses several times greater than that of a free electron; if two deuterons could be bound together with one of these 'heavier' electrons, an interesting fusion rate would result.

But a little learning is a dangerous thing. Electrons in a metal obtain their effective masses because they are not bound to a single atomic site, but move in concert throughout the lattice: push against one, and you push against them all. But if one of these lattice electrons is detached from the system so it can bind two deuterons into a molecule, it is no longer part of the electron collective, and reverts to having its normal mass. In other words, the effective mass of an electron in a solid depends on what you are doing to it, and if you want it to bind an isolated molecule, it can no longer have a high effective mass.

The third broad category of cold fusion theories rested on more sophisticated uses of collective effects in solid-state physics.

The general drift was that deuterons, being panicles of zero spin, could fall into a Bose-condensed state, in which their wave functions were all identical and periodic throughout the lattice. (This condensation can occur only if the temperature of the system is less than a few degrees above absolute zero but, as with the Oppenheimer-Phillips mechanism, it was the principle that mattered.) Once in this condensed state, one deuteron could interact with another at a different lattice site in the palladium, because all the identical periodic wave functions of all the deuterons would have their maxima at the same places.

These theories had the special attraction that they could easily be decorated with the jargon, at once forbidding and enticing, of solid-state physics: Bose-condensates, Bloch states, Wannier functions . . . like the Paris fashions, they outface mockery.

Nevertheless they were all wrong, and for another straightforward reason. The fusion rate for two deuterons is calculated from their two wave functions, multiplied by the nuclear interaction rate. The latter is a very short range force; only at separations of a few nuclear radii is the nuclear reaction rate significant. The only important contribution

to the fusion rate, therefore, comes ham the product of the wave functions when the deuterons are very close. But the wave function when the Bose-condensed state are calculated explicitly by ignoring the nuclear interactions; they are valid everywhere except at close range. Where the assumptions that lead to Bose-condensation are correct, the fusion rate is negligible; where the fusion rate might be significant, the Bose-condensation model is wrong,

All cold fusion theories put forward so far can be demolished one way or another, but it takes some effort. Although cold fusion was, in terms of 'ordinary' physics, absurd, it was not obviously so; it contravened no fundamental laws of nature. This made it easy for advocates of cold fusion to insinuate that some arcane but genuine phenomenon of quantummechanical solid-state physics might provide a credible theoretical foundation, and likewise made it impossible for skeptical physicists to give any clear and general proof that cold fusion could not work; all they could do was rebut one daft idea after another, and even that required a good deal of patient explanation.

But it has to be said that one of the reasons that Pons and Fleischmann prospered early on was that few people were willing to stand up and say why they thought cold fusion was nonsense. (One or two physicists suggested in private that it was up to this journal to take on the task in its editorial pages). After the 23 March press announcement, the response of most experts consulted by science reporters was academically correct but journalistically weak. It's a very interesting idea, was the gist of the scientific community's opinion, and we really can't say what we think of the experiments until we've seen more details, or tried it for ourselves, or consulted our colleagues in the chemistry department. This measured skepticism, contrasted with the unhesitant declarations coming from Pons and Fleischmann, sounded like academic nose-holding, as if physicists knew they had been beaten but could not bring themselves to admit it.

Perhaps science has become too polite. Lord Kelvin dismissed the whole of geology because his calculations proved that the Sun could be no more than a few million years old; Ernest Rutherford is still remembered for his declaration that talk of practical atomic energy was "moonshine"—but the stature of neither man has been noticeably diminished by their errors which were as magnificent as their achievements. Kelvin and Rutherford had a commonsense confidence in the robustness of their judgments which the critics of cold fusion conspicuously lacked. Would a measure of unrestrained mockery, even a little unqualified vituperation, have speeded cold fusion's demise?

44) Before Going to Salt Lake city

Ludwik Kowalski (February 14, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

Let me begin with a message which I posted on the Phys-L discussion list several days ago. I wrote: “Two more items were added to my cold fusion site at:

http://csam.montclair.edu/~kowalski/cf/

You will recognize some voices from our recent debate. I also had an item written in January but decided not to post it. The item started like this: “What did I see today (1/19/03) in Salt Lake City?

a) An example of conspiracy to deceive by presenting fraudulent data? To what purpose?

b) A manifestation of a large scale self-deception involving hundreds of Ph.D. scientists in several countries? If this is possible then how do we know that it does not exist in other scientific areas?

c) Experimental support for a claim that nuclear processes can be initiated at nearly room temperatures? How can this be explained?"

Then I described what was shown to me and what I was told about it. I am not posting this message because I was invited to participate in the next experiment. I will be in a better position to write about this in March, after the experiment. They will show me how radioactivity of thorium nitrate (dissolved in water) can be practically eliminated in 30 minutes through a process involving an electric current of 5 A at 60 V. I do not believe that this is possible; my null hypothesis will be that radioactivity which was lost (if it was lost) went somewhere else. But what if attempts to find radioactivity in suspected places fail?

Then I will be able to say that a nuclear process (in this case turning radioactive isotopes into stable isotopes) can indeed be induced in a very unusual way. It is fun speculating about such possibilities. Such speculations are nothing more than wishful thinking; they are in conflict with what we have learned about nuclear phenomena. But rejecting experimental facts because they disagree with what we think should happen is not appropriate.

By the way, E. Storms just posted a LONG review of the entire CF field. He decided to call it a "student's guide." I would not offer it to my undergraduate students; the guide is for those who are prepared for study the field at an advanced level. But that only my personal opinion. In any case, this review is at:

http://www.lenr-canr.org/StudentsGuide.htm

Do not expect to digest it in ten or twenty minutes.” That was posted on 2/10/03. Let me add to this a summary of the 1997 and 1998 articles describing the Salt Lake City work. I composed it for myself but decided to share it. The essay begins on the next page.

A new kind of alchemy? Will it be confirmed?

Ludwik Kowalski, 2/13/03

Introduction

As most people know, chemistry evolved from alchemy, just as astronomy evolved from star gazing and from astrology. Alchemists tried to produce gold from less expensive elements. They failed and this led to the realization that chemical elements are immutable. The idea of immutability of elements, confirmed by all chemical experiments, is no longer as absolute as it used to be; we know that nuclear reactions often result in transmutation of elements. But this happens only when kinetic energies of subatomic particles (neutrons, protons and their aggregates) exceed those encountered in ordinary chemical experiments. An observed transmutation of elements at low temperature, if confirmed, would indicate that subatomic particles are somehow accelerated to unusually high energies.

Suppose that the potential difference between two electrodes is 100 volts. It could be used to accelerate protons to an energy of 10 eV. This is not sufficient to overcome an electrical repulsion of atomic nuclei. But suppose that a proton is attached to a cloud of a million electrons. (Speculations about the possible stability of such a cloud are described in Appendix 2.) A proton attached to the cloud, in traveling toward the positive electrode, could gain kinetic energy of ten million eV. This would be sufficient to penetrate a nucleus and cause a nuclear reaction. The purpose of this essay is to summarize two articles about experimental evidence of nuclear transmutations occurring in simple tabletop experiments. The authors of the articles, Hal Fox and Shangxian Jin, invited me to work with them and I will summarize what I know about their work. I plan use this essay as a basis for writing about the outcome of my ten-day-long visit to their private laboratory. This summary is limited to experimental facts; comments and tentative speculations are to be found in appendices. The articles were published in the Journal of New Energy (1,2); Hal Fox, from Salt Lake City, is the editor of that journal.

Experimental Setup

The setup, called LENT-1 reactor, was essentially a vessel with two electrodes made of oxidized zirconium. It was partially filled with 25 cc of distilled water in which various amounts of thorium nitrate (between 0.1 and 0.5 grams) were dissolved. The vessel was hermetically sealed to withstand high pressures (tens of atmospheres) at high temperatures (up to 500 F). The electrodes were connected to secondary winding of a power transformer (up to 2 kVA). The typical current flowing through the electrolyte was 5A while the effective a.c. voltage was typically less than 100V. The potential differences across the electrolyte were very small in comparison with potential differences along the very thin layers of zirconium oxide covering the electrodes. This fact seems to be significant, as elaborated in Appendix 2.

Thorium nitrate was chosen because it is highly soluble compound containing several radioactive nuclides (^{232}Th in equilibrium with its daughters). The main purpose of the experiments was to show that the initial radioactivity can be reduced very significantly during short time intervals, most often 30 minutes. Let me mention that numerous attempts to reduce radioactivity, shortly after radium was discovered by Marie Curie, were made but they were not successful. According to (3): “High and low temperatures were tried, strong electric and magnetic fields were applied, tremendous pressures, and the strongest possible chemical reagents were put to use, but not a single one of the most powerful weapons of the physical laboratories affected the radiation of energy by radium.” In that context the findings of Fox and Jin are very puzzling. At present I accept their data but during the experiments my position will be different; I will do everything possible to question their findings. But I will be open-minded; I will change my skeptical attitude if we fail to contradict the data.

Summary of experimental results

The authors write that it took them three years to develop a procedure for the effective transmutation in the LENT-1 reactor. Over a dozen successful experiments were performed. The method used consisted of comparing radioactivity “before” the current was turned on with radioactivity “after” the current was turned off, 30 minutes later.

1) A Geiger counter measuring radioactivity of the electrolyte showed practically nothing but the background after the

processing. The level of a constant radioactivity before the experiment was “considerably above the background.”

2) The same counter was used to measure the radioactivity from the surface of electrodes. The electrodes were not radioactive initially but became radioactive after 30 minutes of processing. The most remarkable was that the surface radioactivity was not constant, it decreased, more or less exponentially to a constant level (about 90 counts per minute) after 200 hours. This was interpreted as an indication that relatively short-living radioactive nuclides were formed through nuclear reactions.

3) A mass spectroscopic analysis of electrolyte, performed in a specialized laboratory, showed that 95% of thorium was lost. This was consistent with what has been inferred from the Geiger counter data (see point 1 above).

4) The second article of Fox and Jin focuses on the use of two gamma ray spectrometers, one using a pure Ge detector. The mass spectrometric analysis showed that the amount of Th in the electrolyte was reduced from 4399 ppm to 9.5 ppm. This confirmed findings reported in the first article.

5) The below shows the cutaway view of the vessel and the location of the Ge detector. The gamma ray spectra (actually shown in the publication) were obtained during one hour interval immediately after the end of processing. The vessel was not open and gamma rays had to penetrate the 1 cm wall of zirconium.

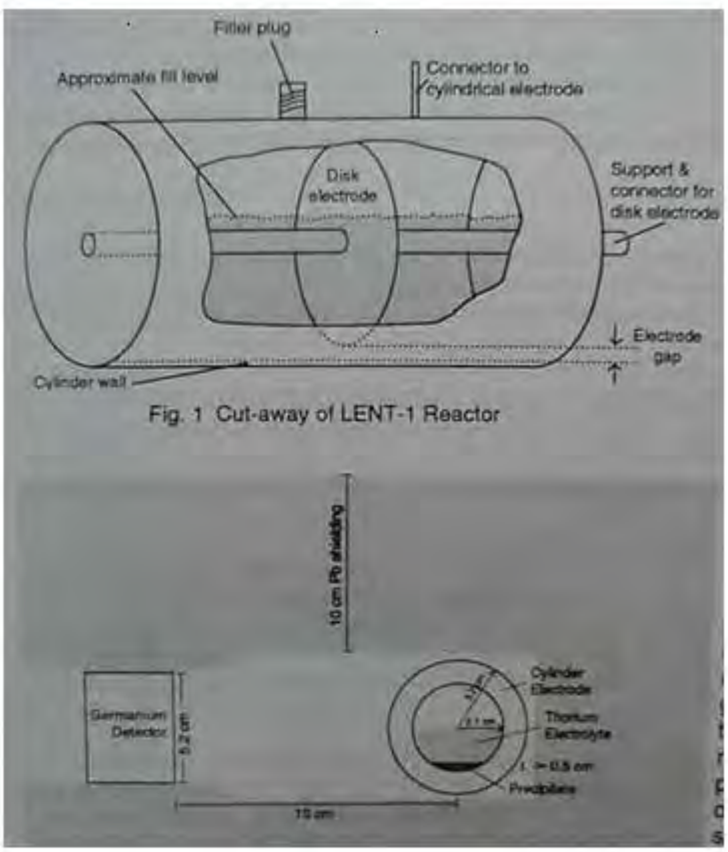

Figure 1.
The setup shown to me was slightly different. It was essentially a zirconium cup whose central electrode (a zirconium rod) was supported by a covering teflon plate.
Intensive underwater arcing and sparking accompany the flow of current.
= =

As illustrated below, the radioactivity from the entire setup (based on four well known gamma ray peaks due to daughters of thorium) was reduced by approximately 50%. This is five times more that could possibly be attributed to a change in the distribution of radioactivity (concentration in the precipitate).

	peak (keV)	net cnts/hr before	net cnts/hr after
^{228}Ac	911	127 +/- 11	66 +/- 8
^{212}Pb	239	421 +/- 22	204 +/- 16
^{212}Bi	727	40 +/- 7	26 +/- 6
^{208}Tl	583	217 +/- 15	105 +/- 15

Is there a contradiction between these results (showing that the loss of radioactivity, due to the prominent peaks was about 50%) and the 95% reduction reported in points 3 and 4? It depends on what fraction of the total radioactivity is represented by the selected gamma ray peaks.

6) In another experiment the setup was left closed for several days before opening it. Then the solution (containing the precipitant) was decanted and its radioactivity was measured using a different geometry than in the first experiment. The mixture was found to contain a significant amount of radioactivity due daughters of thorium, as in the first experiment. The radioactivity of the mixture was significantly smaller than from the initial solution, as illustrated below:

		Initial solution	Final mixture
	peak (keV)	net counts/hr	net counts/hr
^{228}Ac	911	195 +/- 14	75 +/- 9
^{212}Pb	239	1849 +/- 44	612 +/- 25
^{212}Bi	727	76 +/- 9	31 +/- 6
^{208}Tl	583	459 +/- 22	147 +/- 13

7) An additional experiment was conducted to demonstrate that only a small fraction of thorium, and its daughters, was deposited on the electrodes during the processing. This allowed authors to conclude that a significant part of the initial radioactivity was destroyed in 30 minutes of processing.

45) Experiment in which I participated

Ludwik Kowalski (March 6, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

1) Imagine the following experiment. The lead nitrate salt, which is not radioactive, is dissolved in distilled water. Two zirconium electrodes, inserted into the solution, are connected to the output of a transformer whose effective difference of potential is 300 volts. A current of several amperes is allowed to flow through the solution. Intensive arcing and sparking takes place inside the liquid. After about thirty minutes of processing the voltage is turned off and the radioactivity of (a) solution, (b) electrodes, and (c) precipitate are measured with a NaI gamma ray detector. That was the first experiment in which I participated last week in Salt Lake City. No radioactivity exceeding the natural background was found.

Why would anyone bother to conduct such an experiment? Because in earlier experiments (1,2) the thorium nitrate was used under identical condition and a sizable reduction of radioactivity was observed. Was this an indication that nuclear reactions were induced by the current or was it simply an indication that some thorium (or its daughters) escaped into the atmosphere? The easiest way to answer this question was to use lead nitrate, which is not radioactive, and to process it in the same way as thorium nitrate. If thorium and its daughters are transformed via electrically-induced nuclear reactions then the same is likely to occur in lead. Finding radioactivity in lead, after processing, would confirm the reality of highly unusual nuclear reactions.

Hal Fox, who invited me to his lab, still thinks that nuclear transmutation might occur producing stable (not radioactive) elements. That would be highly desirable; think about turning radioactive waste from nuclear reactors into stable products. That is much better than keeping them in Yucca mountain for tens of thousands of years. To test for this possibility the non- radioactive products (several grams of powder) were collected. They will be sent (as soon as funds become available) to a chemical lab to analyze the content. Was the initial lead (or at least a big fraction of it) transformed into elements that were not initially present? That is the question to be answered. Personally I do not expect to hear about new elements. But I am sufficiently open-minded to accept experimental evidence of nuclear transmutations, if such evidence becomes convincing.

2) An experiment to verify the destruction of radioactivity of thorium nitrate, as described in item 44, was also performed by using a gamma ray detector (sodium iodide) connected to a multichannel analyser. The results were negative; the radioactivity after processing (for dominant gamma ray peaks) was not essentially different from that before processing. The activity before processing was measured by placing the thorium nitrate powder on top of the detector, the activity after processing was measured by using essentially the same geometry. Gamma rays after processing were emitted from the remains of electrodes and from the residual powder removed from the vessel after all water was allowed to evaporate.

3) Let me add that the laboratory in which I worked is small. But it has interesting results on separation of precious metals from rocks. The current financial situation of the company is expected to improve.

Addendum (3/11/03)

I think it is appropriate to described what happened after I left the lab. The best way to do this would be to show my replies to messages I received. The first message described an experiment involving thorium nitrate; the gamma activity “after sparking” turned out to exactly the same as “before sparking.” I wrote:

1) I agree with Jin's conclusion (no significant loss of activity resulted from sparking in this trial). Therefore I see no need for using my new program [based on Bateman's formulas]. It was a challenge to create it. Let me know if changes in activity are observed again. Then we can see how this can (or can not) be explained. Keep in mind that a single experiment can never be trusted.

2) I read your two papers (1997 and 1998) again and this reminded me that your processing before was done in a totally different reactor (high pressure and high temperature). Therefore the new observation, even if it is confirmed in the future, is not necessarily in conflict with what was reported before. May I suggest that you use the old reactor again and analyze spectra under the constant geometry condition.

3) The only reason we used open beakers was to create an experiment that teachers could perform. In that sense we did not succeed.

Next came a message from Hal which I quote entirely in my reply below.

On Tuesday, Mar 11, 2003, Hal Fox wrote:

You can not be responsible for what they published.

accelerator.

Somebody reading your two papers (1997 and 1998) is likely to think that the claim was about nuclear reactions taking place, not about the removal of radioactivity from the electrolyte. If I were the coauthor I would insist on publishing (at least in JNE) a short statement that tentative conclusions, described in these papers, were not confirmed in more recent experiments. But I would wait for the result of what you are planning to do before publishing the correction.

> The use of the new type of particle accelerator (which we hope to have running within

> atmosphere) and transmuted to stable elements.

That would be an extraordinary accomplishment. I would be very happy to participate in this project. The success here depends on the ability to generate HDCC carrying protons. Instead of trying to transform heavy nuclides, such as Th , etc. I would begin with very light nuclides because here the coulomb barrier is much lower. What about the reaction Cockroft and Walton used (in 1930) to confirm E=m*c^2 experimentally, for the first time? They bombarded Li-7 with protons (whose energies were up to 0.7 MeV) and observed two alpha particles. Another possibility would be to produce N-13 by bombarding C-12 with protons. The half-life of N-13 is 10 minutes and it emits positrons of up to 1.2 MeV. Positrons annihilate with electrons producing easy to detect 0.51 MeV gamma rays. Keep in mind that I have no data on the corresponding cross sections; one would have to do some literature research to take my specific suggestions seriously. But the general idea of starting with light elements is probably valid.

4) Let me also add that according to what I found today (7/2/2003) at

http://www.earthtech.org/experiments/sparkly/report.html

no evidnce for excess heat was found from a well designed "undewater sparking" experiment. The author was inspired by the results of Hal Fox.

Appended on 5/25/08
1) Today I posted the following message on a private Internet discussion forum for CMNS researchers: "The essence of our CMNS controversy is the 1989 claim made by Fleischmann et al. -- a nuclear process is triggered by a chemical process. Please help me to compose a list of experimental effects that were used to validate the claim. Here is the beginning of my list:
1) Excess heat is orders of magnitude larger than what can be attributed to known chemical reactions.
2) Excess heat (produced in a cell whose electrolyte is made from heavy water) is correlated with production of 4He. The amount of excess heat is close to 23 MeV per atom of produced helium. In other words, helium is the nuclear ash.
3) The isotopic composition of an element, after a chemical (atomic or molecular) process is significantly different from the composition before this process. Diffusion of a gas through a solid, by the way, is an atomic process.
4) Energetic nuclear particles, not attributable to cosmic rays or contamination, are detected during a chemical process.
5) The amount of a radioactive substance is REALLY changed during a chemical process (by much more than expected on the basis of the half-life).

The "really" is worth emphasizing. I once participated in a demonstration in which the destroyed-radioactivity effect turned out to be apparent, and not real. Radioactivity was redistributed during high-voltage electrolysis and the counting geometry changed. What was originally in the electrolyte was deposited at the bottom of the cell. A more careful experiment, using the same call, showed that the amount of radioactivity, after the experiment, was essentially the same as before the experiment. What else should be added to my list?

Shortly after that, X wrote to me in private:
Ludwik, you stated/** on the CMNS List that you had personally participated in a demo which sounds to me very much like the Cincy Group LENT-1 Radwaste Remediation Reactor of my late friends Stan Gleeson and Don Holloman. Could you please be more specific about the time/place/participants and who did the before-and-after testing?

My reply:
1) Yes, it was something similar to Gleeson's cell. But our experiment was at normal atmospheric pressure (in an open glass beaker, rather than in a hermetically closed metallic vessel). Both electrodes were Zr and we used the AC power supply. I was a guest of Hal Fox; it was my first CF experiment (in 2003 ?). The experiment was performed by me and by one of Hal's coworkers. Hal was certainly involved but his participation was not 100%. He was doing other things at the same time.

2) A salt containing thorium was dissolved in water, the NaI detector of gamma rays was placed on the side of the beaker and gamma radioactivity coming from the beaker was measured. Seven well defined peaks, spread over a large range of energies, were recorded in a multichannel analyzer. Then electrolysis started; it lasted for several hours; I do not recall exactly how long. Water was added periodically to the cell to keep the volume of the electrolyte constant. After that the radioactivity was measured again, for the same time as before the experiment. The seven peaks were again seen in the spectrum but their heights were significantly reduced. So much for the apparent effect.

3) After that we performed the experiment in a different way.
a) We used the same amount of salt as before. But we placed it at bottom of the beaker, distributed evenly.
b) We place the beaker on top of the NaI detector and measured the radioactivity (recording the spectrum of seven gamma peaks)

c) We added water to the beaker and waited till the salt was dissolved.
d) We started electrolysis, and kept it going for the same time as before (also adding water periodically)
e) At the end of electrolysis we placed the beaker on top of the hot plate and allowed all the water to evaporate.
f) A solid deposit was formed at the bottom of the beaker. It consisted of the initial salt, pieces of Zr, and who knows what else.
g) The beaker was then placed on top of the same NaI detector, in exactly the same position as before electrolysis.
h) Radioactivity was measured, for the same duration as before electrolysis. Each of the seven peaks, after electrolysis, was nearly the same as before electrolysis.

The experiment was designed to produce a clear yes-or-no answer to a well formulated question--is gamma radioactivity reduced or not reduced during electrolysis. And the answer was no. The apparent reduction of radioactivity (in the first experiment) resulted from the fact that its distribution after the electrolysis was not the same as before electrolysis. The "centrum of radioactivity" after electrolysis was further away from the detector than before electrolysis. The second experiment eliminated this effect. I wish other CF experiments, in which I participated, also produced unambiguous answers.
P.S.
Please do not share this description with others. It was Hal's experiment, not mine. My only contribution was to perform the experiment as described in 3 above.

46) Charlatans versus scientists

Ludwik Kowalski (March 7, 2003)

Return to the clickable list of items

An interesting paperback book was published in 2003 by Keith Tutt in England. The title is "The Scientist, the Madman, the Thief and the Lightbulb." The book begins with the biography of Nikola Tesla, goes over the alleged discovery of Henry Morey from Salt Lake City (1930's) and then focuses on recent episodes, including that of cold fusion. In chapter 11, entitled "Of Charlatans, Conspiracies and Skeptics" the author gives a description of schemes by which con artists take advantage of naive expectations of many investors and convince them to finance unreasonable, often non-existing projects. One recent episode of that kind involved an Australian manipulator, Brian Collins.

He was claiming to invent a miraculous energy-making machine "measuring just 12 inches by 3 inches and weighing only 10 pounds. During the tests the machine was said to produce enough electrical energy to completely power an average size home..... With the availability of unlimited amounts of affordable electric energy, individuals can at last pursue their creative aspirations in a new age of society. In a longer description of the device, published at the same time, the claims are even more generous: "The prototype .....produced electrical energy in excess of 1000 kW, enough power to satisfy the energy needs of 100 domestic dwellings at average load demand."

Exploiting naive desire to get rich from free energy Collins wrote: "The special few who sent funds ..... for every dollar that they sent, they'll see more money than they ever believed possible,.....[I]n the next few weeks there could be some amazing things happening that could see many, many times the funds returned to everybody." But several months later, when money was collected, he apologized that he had been misled by his scientists about the status of the generator. The only persons who benefited from the fraud were Collins and his associates.

In reading numerous books critical of cold fusion I never encountered an accusation of fraud directed to Fleischmann and Ponds or to those who carried out additional investigations in thirteen years after the initial announcement. I saw accusations of misinterpretation, lack of expertise, self-delusion and inappropriate methodology but no accusations of deliberate deception or fraud. The only exceptions were words attributed to an MIT professor Ronald Parker. According to a journalist, Nick Tate (Boston Globe, May 1, 1989), cold fusion was denounced by Parker as "scientific schlock." But in a news conference next day the professor denied using these words.

On the other hand, I encountered one accusation of fraudulent manipulation of data on the part of critics of Fleischmann and Pons. According to E. Mallove, the chief science writer in the MIT's press office (who had access to nearly all the information that was put out by the Plasma Fusion Center) there was a deliberate campaign to discredit cold fusion. Those who orchestrated the campaign (Parker among them) were motivated by the desire to protect their own projects supported by the government ($ 200,000,000 per year). Mallove wrote that "MIT as a whole did, indeed, acquire the deserved reputation as a 'bastion of skepticism' on cold fusion. . . . They suspected that..... if the public were to have a too open-minded attitude toward..... the cold fusion, funding for their [hot fusion] program would be endangered. Assuming this to be true one is tempted to criticize the motivation based on financial self-interest. Scientists are expected to be objective in the analysis of experimental facts and theories. But how can one be impartial when asked to evaluate a competitor?

On page 139 Tuff shows two sets of plots summarizing a calorimeter experiment conducted at MIT. The draft plot, dated July 10, 1989, shows evidence of excess heat, as reported by Fleischmann and Pons. That evidence, however, was removed from the final plot, dated July 13, 1989. I (who discovered the contradiction) asked for the original data but his request was ignored. Mallove believes that this was a conspiracy designed to influence the US Department of Energy.

By the way, a colleague sent me a copy of an interesting article of R. Park. It was published in The Chronicle of Higher Education (vol. 49, issue 21, page b20, 2003). The title is “The Seven Warning Signals of Bogus Science.” You can still access this article at : http://chronicle.com/free/v49/i21/21b001.htm

47) Catalytic Fusion

Ludwik Kowalski (March 17, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

Selected articles on cold fusion, from the "Infinite Energy" magazine, can be downloaded from:

http://www.mit.edu/afs/athena/mit/users/r/e/rei/www/CFdir/CFhome.htm

You can find a 1998 interview with Martin Fleischmann and the description of the catalytic fusion, the so-called "Case effect." It is named after Dr. Les Case from New Hampshire. Let me summarize briefly this interesting effect. Case is a chemical engineer who searched and found a catalyst to sustain cold fusion. His approach is not based on electrolysis and it promises to be very efficient. The catalyst is commercially available "activated carbon doped with precious metals such as palladium."

About 50 grams of that material were placed in a closed vessel into which hydrogen gas was introduced. The material was heated at a constant rate to keep the constant temperature of 180 degrees C. Then, without changing the rate of heating, the hydrogen gas was replaced by deuterium. The temperature started to rise till the level of 215 degrees was reached, after about three days. That temperature remained constant for many weeks. The author interprets this rise of temperature as an indication of fusion of deuterium nuclei into helium nuclei. What else can be responsible for the fact that the temperature of deuterium is 35 degrees higher than in ordinary hydrogen? Neither the amount of gas nor the geometry were changed? The rate of heating the catalyst was also the same in two cases.

At the end of the experiment the deuterium gas was removed from the vessel and subjected to an analysis. It was found to contain helium. No helium was present in the gas before it was processed. The concentration of helium, after about one month of processing, turned out to be 11 ppm. This is significantly higher than the concentration of helium in air (5.2 ppm). If the initially pure gas were contaminated with 10% of air, which is highly unlikely, then the amount of helium would be 0.52 ppm. This is is about 20 less that what was actually measured. The author, a chemical engineer working in his basement laboratory in New Hampshire, wrote: "My objective always has been not to play around scientifically, because I am not a physicist, but to head toward commercialization." Then he elaborated on what would it take to make practical generators, first at the domestic 5 kW level and than at the level of 100 MW power plants.

A scientist from the SRI (Stanford Research International) laboratory, Michael McKubre, worked with Case equipment and used his own high resolution mass spectrometer (able to distinguish ^4He from $^4D_2$). After confirming accumulation of helium he makes a classical "scientific method" attempts to justify it presence by trivial factors, such as leakage or contamination. Failing to do this he arrives to a conclusion that helium is really PRODUCED in the chamber: McKubre wrote: “If we observe helium in our experiments it’s either because it leaked in from the atmosphere—we can rule that out by the blanks that we do and the fact that the helium signal that we have seen is larger than the helium in the ambient. It’s possible that the helium preexisted in the sample and was simply released to the gas phase with long term exposure. We can rule that out largely because we’ve analyzed the catalyst that we’re using and found that it contains no measurable levels of helium. The only possibility that remains, and remains to be checked, is that the helium is produced by a nuclear process. “ Is this analysis an example of pathological science? I do not think so; everything that I read in the article seems to be 100% scientific. On what basis could this serious and careful investigation of McKubre be accused to be pseudoscientific?

The scientist also makes an attempt to correlate the amount of helium produced with the amount of the excess heat generated. Expectations are not hard to formulate. It is well known the energy released from $^2D+^2D-->^4He$ fusion is 23.8 MeV. In hot fusion this energy appears in the form of gamma rays, in cold fusion it seems to appear in the form of heat. That is one of the mysteries of cold fusion. Assuming the excess heat is generated at the level one watt, and using the above 23.8 MeV value, one can easily show that $2.62*10^{14}$ atoms of helium must be produced in each second. McKubre recognizes that his apparatus was not actually built to do very accurate calorimetry. But it is good enough to say that the rate of helium production is roughly consistent with what is expected. He plans to build a better apparatus and to return to this subject in the future. Is this pathological science? I do not think so. It is interesting to speculate how would cold fusion be received by the scientific establishment if Fleischmann and Pons did not announce the discovery of excess heat till the evidence for the commensurable amount of helium could be demonstrated.

The McKubre does not go away from recognizing weaknesses that must be overcome in order to convince skeptics that the effect is real. He wrote: ”One of the difficulties in the cold fusion field is the apparent lack of reproducibility of experiments: many people performing the same experiment get apparently different results; different experiments performed in the same laboratory give apparently different results. So it’s obvious that if you do the same thing you must always get the same result. What this is telling us is that there are some important parameters of our experiments that are not under our control. Some of them I know and understand, and still [we] can’t control some of these parameters we don't know about yet. We just don’t know what the process is that we are studying, so we don’t know what parameters we need to control in order to yield a consistent result. An experiment which always gives the same result --can be performed in several different laboratories to yield the same result -- would be very valuable to us, in part in helping to convince the remaining skeptical scientists in the world that there is a phenomenon to observe. But, in fact, in order to use the scientific method to observe scientific results, we have to be able to reproduce the results of our own experiments so that we can see what the effects of small changes are on these experiments.”

How does this differ from an investigation in so-called “mainstream science?” Preliminary results are always tentative and additional studies are conducted to reach the desirable level of control. After describing his investigations McKubre refers to another very convincing illustration of cold fusion. He describes the work of two Japanese scientists, Arata and Zhang, who also observed accumulation of helium in a very different experiment. McKubre does not hide the fact that this very sophisticated experiment was performed only in one laboratory in Japan.

He writes: “what we are attempting to do here is to produce their same results with their apparatus and with their help. This is a collaborative effort between Arata and Zhang and the SRI group, to produce in *our* laboratory the same results as they have obtained repeatedly over the years, which would indicate that we have some degree of mastery over the experiment. The experiment that we have running here, in fact, is relatively young; it hasn’t been operating for very long. One of the difficulties with Arata’s experiment is that it requires many, many months to produce a result, and quite literally we’re not very experienced with Arata’s methods, so we’ve had some difficulty getting his experiment set up and operational. Certainly, it’s caused me to have an increased level of respect for Arata and Zhang’s technical competence. They are very, very good scientists. Within a month or two, we hope to have reproduced their experiment faithfully and reproduced their result. And the benefit will be in part sociological. We will demonstrate that an experiment can be transported from laboratory to laboratory and yield the same result. It will also give us something that we can do again ourselves and define somewhat the parameter space in which these experiments yield excess heat and, apparently, helium-3 and helium-4.”

Why are experiments of that caliber not evaluated, or criticized, by those who decided, in 1989, as rapidly as possible, that cold fusion is “pathological science?” I view the Japanese experiment as a hybrid between electrochemistry and catalytic fusion. The palladium cathode in their experiment is not a rod, as in many electrochemical setups, but a thin walled vessel whose walls are penetrated by D atoms. The space inside the palladium vessel contains tiny grains of palladium power. Production of helium presumably occurs on the surface of palladium grains. A high resolution mass spectrometer was used to analyze the gas accumulating inside the vessel. The system is designed to establish a correlation between the excess heat and the amount of helium produced. Results are said to be highly reproducible. But the results must be reproducible by all qualified scientists, at least at the level of 20% accuracy, in order to become a firm proof of the reality of cold fusion.

48) High Density Charge Clusters

Ludwik Kowalski (March 25, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ

Return to the clickable list of items

One paragraph was removed from the initial draft at the request Hal Fox. The content of that paragraph, he wrote, might interfere with a current patent application.

During my research trip to Salt Lake City I learned about the idea of high density charge clusters. Kenneth Shoulders has several US patents devoted to technology of charged clusters. He discovered them experimentally (in early 1980's) by observing tiny holes produced by electric sparks on surfaces of several materials. The observations were made by using a scanning electron microscope. Shoulders claims (1,2) that under certain conditions roughly 10^{11} electrons can cluster in a region whose size is very small (one micron or so) and move as a single particle-like unit. That unit, called charge cluster (CC), has the same q/m ratio as a single electron. Accelerated across a potential difference of only 10 volts, for example, the CC would acquire the kinetic energy of 10 eV per electron, or 1,000,000 MeV per cluster. The speed acquired would be $1.87*10^6$ m/s. A small number of protons, for example, one per million electrons, can be trapped in a cluster. These protons would have the same velocity as CCs. In other words, the kinetic energy of each proton would be 18,351 eV. This is 1835 times more than a single proton can possibly acquire from the same difference of potential.

But electrons separated by very small distances repel each others. How can a CC remain stable? This is a theoretical question; I do not know how to answer it. But I did read a paper (3) devoted to this difficult question. The authors claim that CCs are toroidal and that electrons move rapidly with respect to the center of mass. The magnetic field generates forces which overcome the repulsion. It is hard for me to accept this explanation; I know that it would not work for two beams of electrons traveling along parallel paths in the same direction with the same speed. Why not? Because the attractive magnetic force (per unit length) is always smaller than the repulsive force dues to electrostatic forces.

According to a recently published book (4) Shoulders described the idea of CC to Richard Feynman. The great scientist rejected the idea at first. But then he wrote (5): "when you were in my office I could not see how 10^{10} or 10^{11} electrons could be kept as a ball in a vacuum without ions. So I was skeptical and didn't let you tell me about them. I must apologize for it has come to my attention that it is indeed possible . . . Now that I understand how it might work, I should be glad to discuss it again anytime you wish." Jin and Fox (1) refer to several theoretical papers devoted to CCs (6,7,8).

49) AFTER MY COLD FUSION NOTE WAS REJECTED BY THE PHYSICS TEACHER

Ludwik Kowalski (4/3/03)
Montclair State University, Upper Montclair, NJ, 07043

Return to the clickable list of items

My cold fusion note, submitted to The Physics Teacher, was evaluated by two referees. Their recommendation was not to publish it. The editor wrote to me: "Our editorial staff has completed its review of your manuscript 'On Reproducibility of Data in Cold Fusion Experiments.' The process included consultation with two of our referees. I regret to inform you of our decision not to publish the paper. The first referee offered only brief comments: 'I don't think The Physics Teacher is the right journal for this paper. Most readers of this journal are in no position to judge these rather esoteric matters. Indeed, most teachers wouldn't know what the fuss is all about.'

The second referee's comments are attached [see below]. In the light of the referees' comments and of our own careful reexamination of the manuscript, we believe that TPT readers would not be able to make sufficient use of the paper to warrant its publication. While we are not able to use the manuscript you submitted, we appreciate having had the opportunity to read it and we are grateful for your continued interest in The Physics Teacher." The second referee wrote:

"I must recommend against publication of this paper in *The Physics Teacher*. Despite the claim of 'helping us teachers,' the paper seems actually to be an attempt to have a serious journal endorse cold fusion as a research field to be taken seriously. The pages of *The Physics Teacher* are not the appropriate place to make such arguments. The author says that 'its main claim, the discovery of unexplained heat, was not challenged.' The quoted assertion is totally incorrect; the claim was indeed seriously challenged. And the author dismisses the observation that those neutrons were not observed (and never have been observed, to my knowledge) as somehow being merely a 'tactical error' on the part of Fleischmann and Pons. I don't understand how that statement is supposed to get around the lack of neutrons. Whatever the tactical failings of F&P might have been, they do not hide the absence of those neutrons. Even if there were some validity to the now 14 years' worth of attempts at cold fusion (I haven't heard of any), *TPT* is about the last place in the world for this to be published."

The purpose of this note is to share my paper over the Internet and to react to the comments made by the second referee. The last sentence shows that this referee is not aware of recent cold fusion publications. why was s/he selected? Can a nuclear process of some kind be triggered by a chemical process? The answer, based on what I know about nuclear physics, is negative. On the other hand I read descriptions of many experiments which seems to indicate the opposite. These experiments were performed many years after the first evaluation of "cold fusion" was made by DOE. They were performed by reputable scientists in several countries. As a physics teacher I would very much appreciate a second evaluation of the field by a panel of competent investigators. I am no longer comfortable saying that "cold fusion is pseudo-science."

ON REPRODUCIBILITY OF DATA IN COLD FUSION EXPERIMENTS

Ludwik Kowalski

Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Those who followed the discovery made by Fleischmann and Pons (1) are likely to remember that the number of teams confirming cold fusion was about the same as the number of teams not able to confirm it. The claim was that palladium loaded with deuterium ions generates thermal energy which can not possibly be attributed to chemical processes. According to (2,3,4) the reproducibility of the effect is much better today than it used to be. But that does not mean that the experiment is easy.

Here is how the situation was described by experts (3). "Most scientists hold the view that anomalous effects in deuterated metals can be explained by experimental errors. Some scientists go so far as attributing positive results to self-deception and even fraud and consign this phenomenon to the realms of Langmuir's 'Pathological Science.' Due to the lack of experimental reproducibility, this field remains practically defenseless against such attacks. To our knowledge, no laboratory can provide detailed experimental instructions to another laboratory and guarantee the reproducibility of the excess heat effect. Nevertheless, considerable knowledge has been gained concerning experimental conditions that favor the excess heat effect. . . Our experiments indicate that the lack of reproducibility is due largely to unknown and uncontrolled variables contained within the palladium stock.

. . .[Our results] have been used to support both sides of the scientific controversy regarding anomalous effects in deuterated metals. Our first set of experiments conducted over a 6-month period (25 March - 7 September 1989) produced no significant evidence for any excess enthalpy produced. . . [Other groups] also reported no evidence for excess heat, thus greatly impacting the general scientific opinion regarding this field. All three [of these] groups discontinued their experiments after only a few months of investigation. We continued to investigate other palladium samples and eventually observed significant evidence for excess enthalpy from the use of Johnson-Matthey palladium rods. In retrospect, it would be impossible for any research group to adequately investigate the multitude of variables involved with this field in only a few months. These variables range from the palladium metallurgy to the D_2O purity, the type of electrolyte and its concentration, the electrochemical cell, the electrode arrangement, the type of calorimeter, proper scaling of the experiments, the handling of metals, the current densities used, the duration of the experiments, the loading of deuterium into the palladium, the use of additives, and so on."

This was written in 1996, seven years after the field of cold fusion was declared a scientific fiasco (5,6). I strongly recommend (2,3,4) to those who would like to build an electrolytic setup demonstrating the reality of excess heat. It is clear to me that naming the unknown phenomenon "cold fusion" was most unfortunate. The new (awkward) name is "LENR-CANR," where LENR stands for "low energy nuclear reactions" and CANR stands for "chemically assisted nuclear reactions." Yes, I know that LENR has already been chosen for something else and that CANR contradicts everything we know about atoms and nuclei. On the other hand I believe that those who now routinely observe excess heat are experienced and honest scientists. The term AE (anomalous energy) is also used, instead of cold fusion, when the emphasis is on excess energy. Personally, I prefer to retain the original CF abbreviation interpreted as "cold furor" (7)." In any case the discovery of CF was not a passing episode; several hundred people have been working in the area since the big excitement of 1989.

Up to now the field, far from being a fiasco (6), still can not be called scientific because highly trained scientists have often been unable to reproduce each other's experiments, even qualitatively. But due to persistent efforts of many dedicated researchers the CF field is becoming scientific. According to (4), "excess power levels below 20% are routine [but considerable skill is required] while values above 100 % are rare. The highest reported excess power is 1500% using palladium deutride made in a fused-salt

electrolytic cell at 450 ^{o}C." Theoretical models will probably be developed as soon as basic facts are finally recognized. Practical applications are possible but it is probably too early to speculate about them. On the other hand, I think that discussing CF with students is highly appropriate, especially in the contexts of the methodology, history and sociology of science.

The early history of CF is outlined in (6), and in other books (7,8,9,10,11,12). According to (6), the year during which the discovery of CF was announced was like a soap opera. "Confirmations, retractions, new positive claims and null results were the order of the day…" partly due to the very unconventional form of the announcement -- via a press release, rather than publication in a peer-reviewed journal. Furthermore, many important details were not initially available to those who wanted to conduct similar experiments, most likely on the advice of lawyers handling patent applications.

The essence of the discovery, as described in (1), can be summarized as follows. Heavy water was decomposed in an electrolytic cell whose cathode (negative electrode) was palladium and whose anode (positive electrode) was platinum. The amount of energy entering the system was found to be smaller than the amount of energy exiting the system. The law of conservation of energy requires that a process of some kind must be responsible for the anomalous energy. The hypothesis put forth by Fleischmann and Pons was that the AE was generated via fusion of atomic nuclei. The only reason to advance that hypothesis was the realization that the generated heat was too large to be attributed to a chemical process. This, however, antagonized scientists familiar with nuclear fusion; how could they accept an ad hoc hypothesis contradicting accepted concepts?

But there was an additional, equally good, reason for rejecting the hypothesis. Fusion of deuterons (atomic nuclei of deuterium) is known to produce neutrons, protons, tritons and, very rarely, ^{4}He. Assuming that the fusion hypothesis was correct, scientists quickly calculated the amount of byproducts from the reported magnitude of AE. The actual amount found was much lower than what was expected; the discrepancy was at least ten orders of magnitude. This did not prevent Fleischmann and Pons from saying: "it is evident that … nuclear processes must be involved." I think that linking an experimental discovery with a hard-to-accept
conclusion (and calling it evidence) was a tactical error. Another tactical error was saying that the discovery was ready for practical exploitation.

The panel of scientists appointed by the US Department of Energy correctly concluded, in their Executive Summary (5), that "the experimental results on excess heat from calorimetric cells reported to date do not present convincing evidence that useful sources of energy will result from the phenomena attributed to cold fusion. In addition, the Panel concludes that experiments reported to date do not present convincing evidence to associate the reported anomalous heat with a nuclear process. The Panel also concludes that some observations attributed to cold fusion are not yet invalidated."

There would have been no need for the first two Panel conclusions if Fleischmann and Pons had not made those tactical errors. And the third conclusion was not at all negative; how can a discovery of a totally new, and difficult to observe, phenomenon be validated in less than one year? In other words, the CF field was criticized for its two marginal claims; its main claim -- the discovery of unexplained heat -- was not challenged. The field was nearly discredited by two premature claims. The last sentence of the Executive Summary stated that the Panel was "sympathetic toward modest support for carefully focused and

cooperative experiments within the present funding system." As a teacher who, until very recently, was not paying attention to developments taking place in the area of CF I would welcome its revaluation. Dedicated scientists working in that area would probably also welcome the initiative. The reevaluation might lead to the end of the isolation in which they found themselves after the Panel Report to the United States Department of Energy was published. And it will help us teachers.

Comments on what the second referee wrote

I was wrong to write “the discovery of unexplained heat, was not challenged.” Many scientists were not able to reproduce the experiment described by Fleischmann and Pond. Given a chance I would correct the unfortunate assertion. The reviewer also wrote: “the author dismisses the observation that those neutrons were not observed as somehow being merely a ‘tactical error’ on the part of Fleischmann and Pons.” Yes, neutrons were never observed in the amount commensurable with the amount of heat. This supports the view that the reaction (claimed to take place) was not thermonuclear fusion, as we know it. Instead of saying that “something unusual is taking place” Fleischmann and Pons said “it is nuclear fusion.” That is what I meant by tactical error. The biggest mistake, however, was to announce the discovery prematurely.

50) Why Cold Fusion Has Been So Hard to Explain and Duplicate

Edmund Storms
Energy K. Systems, Inc.
Santa Fe, NM

Return to the clickable list of items

INTRODUCTION

Cold fusion (LENR) has been difficult to duplicate and many proposed explanations have not helped to solve this problem. I suggest the difficulty is caused by an erroneous assumption. LENR reactions obviously do not occur everywhere in nature. Painful experience has shown that they occur only in special and difficult to create materials, the so-called NUCLEAR ACTIVE ENVIRONMENT. In the past, people have assumed that the NAE is in the bulk of a Pons-Fleischmann (P-F) palladium cathode. The surface of the cathode is assumed to be inert and only serves to modify the composition of the underlying beta-PdD. In contrast, I'm proposing that the surface layer itself is the NAE.

The concept of NAE is difficult for people trained in physics to accept because phenomenon studied by physics, particularly nuclear physics, are independent of chemical form. For example, when sufficient plutonium is brought together in one place, the resulting nuclear reaction does not depend on whether the material is the carbide, nitride or oxide. However, in the case of LENR the environment is very important. When the proper environment is achieved, the nuclear reaction occurs spontaneously, with no additional effort required. A person does not have to understand the mechanism of the process. Unfortunately, most theories have focused on the mechanism rather than on the environment. To make matters worse, the mechanisms are applied to ideal, imagined materials, not to those existing in the real world. As a result, little useful progress has been achieved.

DISCUSSION

To discover the properties of the NAE, it's location on the cathode must be determined. The following observations suggest that it is located in the surface region of the cathode.

1. Helium generated by LENR is found in the surrounding gas rather than in the palladium deuteride.

When helium is placed in palladium using decay of dissolved tritium, the resulting ^{3}He can be removed only by heating near the melting point [1]. Only helium located near the surface is able to leave the material without this treatment. Therefore, the observed anomalous ^{4}He must have been generated very near the surface of a P-F cathode to be observed in the surrounding gas.

2. Anomalous tritium is detected in the electrolyte rather than in evolving gas.

Tritium that is known to be present within the cathode can be displaced by deuterium during electrolysis. This tritium is found to leave with the evolving deuterium gas [2]. However, tritium produced during a cold fusion reaction is found in the electrolyte, provided a recombining catalyst is not present in the cell. Tritium is able to enter the electrolyte as T+ because it is able to exchange with D+ at the cathode surface before it has a chance to form DT molecules, which would leave as gas.

3. Anomalous heat is observed to be generated on the cathode surface.

Szpak et al. [3, 4], using an IR camera, observed hot spots that turned on and off in rapid secession on an active cathode . The generated energy was claimed to come from just below the surface.

4. Transmutation products are located only in the surface region.

A number of studies have detected transmutation products located within the surface region of P-F cathodes. These elements do not exist within the bulk material[5-9].

5. Melted regions are observed on the cathode surface.

Microscopic examination of the surface shows many melted regions after anomalous energy has been generated[10].

6. Large amounts of anomalous energy can be generated using thin films on an inert substrate.

Significant anomalous energy has been generated using very thin films of material[11-13]. If a large amount of palladium were required, as would be present in bulk material, these thin films would have produced very little anomalous energy.

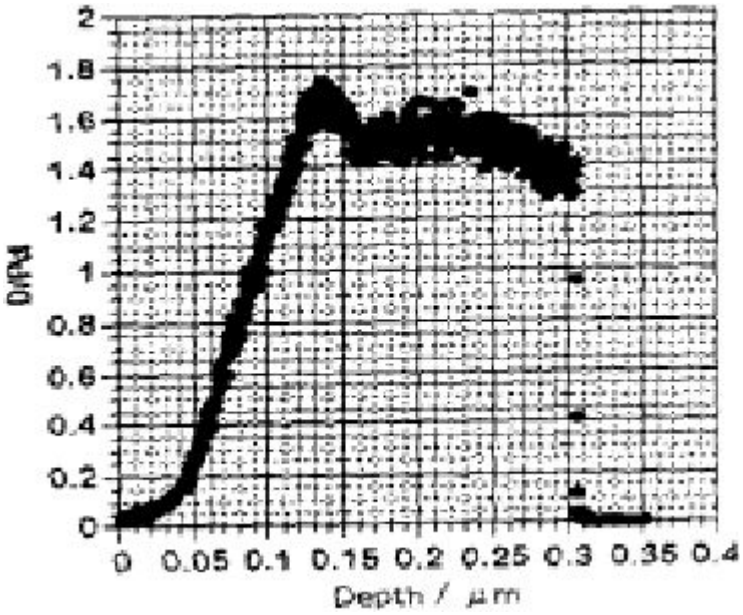

FIGURE 1. Deuterium concentration in Pd after electrolysis based on ERDA. [14] Some deloading from the surface is evident.

Next, the deuterium content of the NAE needs to be discovered. Unfortunately, this property is difficult to measure. Reported values are always based on the average composition, not the composition of the surface. Two efforts to measure the composition near the surface are shown in Figs. 1 and 2. The D/Pd ratio of the NAE will be greater than these values.

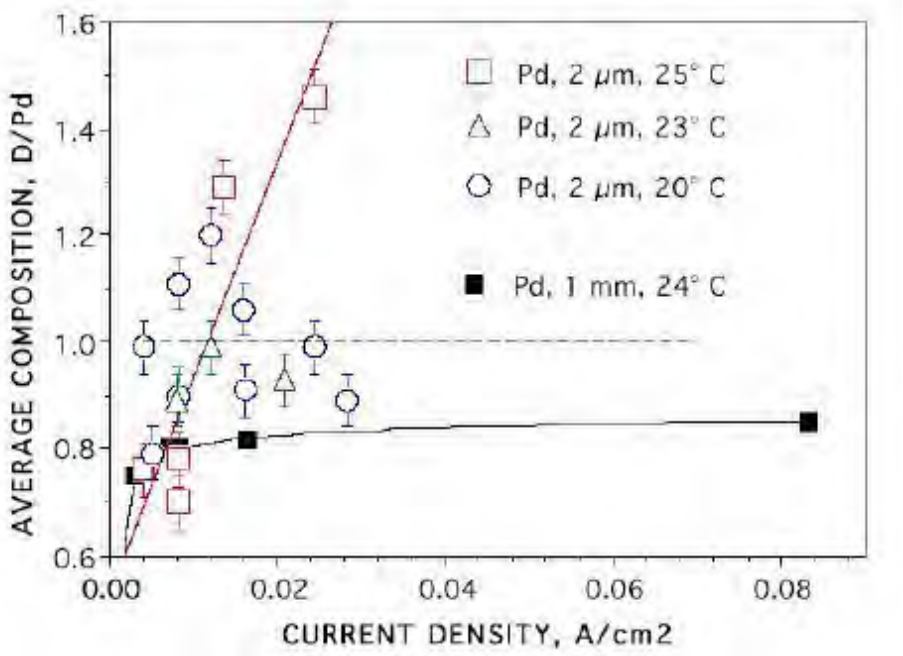

FIGURE 2. Deuterium content in Pd films plated on Pt after electrolysis based on orphaned oxygen. [15] Film thickness and temperature are indicated.

These measurements indicate that the NAE has a composition in excess of PdD1.7. The beta phase has a limiting composition of PdD1.0. Therefore, the NAE can not be beta-PdD. Of course, some people will argue that the additional D+ goes into tetrahedral sites. However, no evidence exists for occupancy of this site. In fact, if this site were occupied, a change in crystal structure would be expected as experienced by hydrides formed by other metals. For example, other metals form hydrides having a limiting composition of MH2, in addition to MH. An example is shown in Fig. 3 for the Zr-H system. The ZrH_2 structure is fcc tetragonal, as would be expected if D+ occupied both tetrahedral and octahedral sites and had an ordered arrangement. If tetrahedral sites were occupied, it is safe to conclude that they would be present in PdD_2 not in beta-PdD. Also, such structures have the potential for the presence of deuterium dimers. Besides having a very high D/Pd ratio, the surface also contains a high concentration of Li, Pt and Si, along with many other elements[8, 16, 17]. Consequently, the surface is a complex mixture of many elements with a very high D/M ratio and an unknown structure.

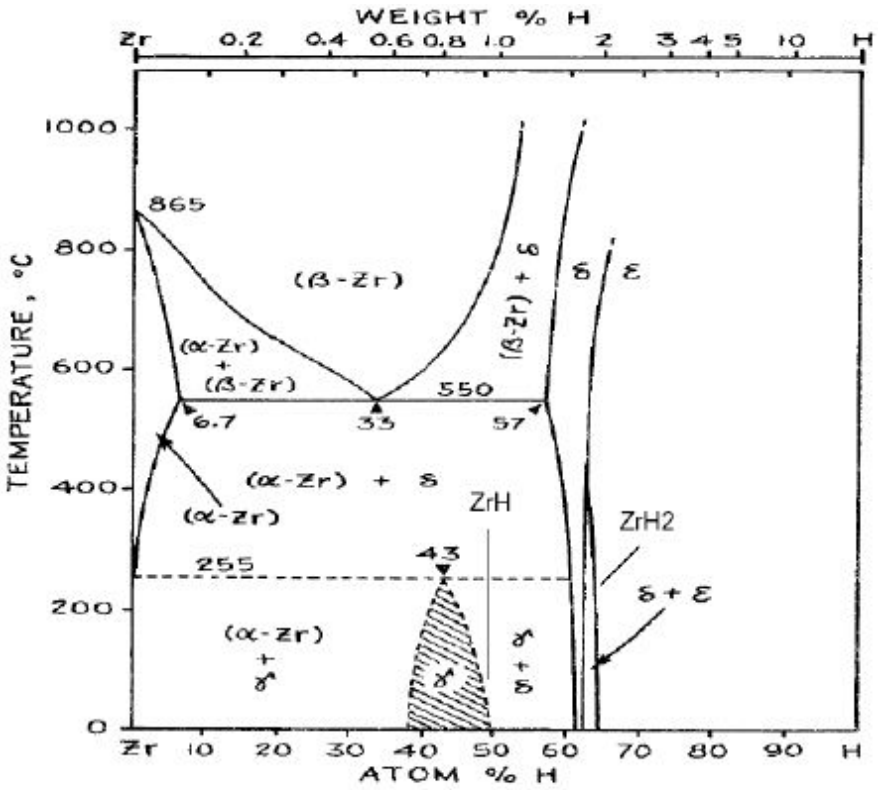

FIGURE 3. Zr-H system at 1 atm H_2 pressure. (GE Handbook of Phase Diagrams).

What other characteristics might the surface layer have? LENR has been produced from finely divided palladium using palladium-black [18, 19] or fine powder attached to charcoal[20]. Even microparticles of other substances imbedded in palladium are found to be active[21]. Examinations of cathode surfaces show the presence of similar microstructures as a result of the electrodeposition process. In addition, successful thin films, as mentioned previously, also contain this type of microstructure. Apparently, structures in the nanometer range of size are frequently associated with anomalous energy production.

CONCLUSION

1. Pure beta-PdD, regardless of its deuterium content, is not the environment in which LENR occurs during the Pons-Fleischmann effect. In addition, the complex alloy in which the effect occurs in this case apparently requires a very high deuterium content.

2. Nearly pure beta-PdD, when it is used as small particles, appears to be active at a relatively low deuterium content.

3. LENR requires nanosized particles and can involve various complex materials, not just palladium.

4. Most theories, mechanisms, and explanations are inadequate because they have not taken these factors into account.

51) Ten Years of US Navy CF Program

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J. 07043

Return to the clickable list of items

I would like to thank William Beaty for telling me about a recent article (New Scientist, March 29, 2003, pp 36-43) on cold fusion research in US navy laboratories. The author is Bennet Daviss and the title is “Reasonable Doubt.” The article is based on research conducted at the US Office of Naval Research laboratories and, presumably, on interviews with some scientists. The reports on the navy research is now available over the Internet.

www.spawar.navy.mil/sti/publications/pubs/tr/1862/tr1862-vol1.pdf

The name of the report, edited by P.A. Mosier-Boss and S. Szpak, is "Thermal and nuclear aspects of the Pd/D_2O system: a decade of research at navy laboratories." It downloads as a pdf file whose size is 3.6 Mb.

At the beginning of his article B. Daviss write: “After more than 200 experiments, conducted over 10 years at various navy laboratories, several of its researchers are willing to declare that these laboratories have played host to events that not only indicate that cold fusion is real, but that can't be explained in any other way.” The author reminds us that “cold fusion has been as respectable in [mainstream] science as pornography in church.” The big issue was how to use public money to support research in that area. The laboratory had a large number of highly qualified electrochemists who were eager to study cold fusion after it was officially declared it to be pathological science. The work was done on “time not claimed by assigned projects . . . using discretionary funds controlled by their department chiefs.”

The article describes work of Pamela Mosier-Boss and Stanislaw Szpak in one navy California laboratory (in San Diego) and that of Melvin Miles in another (China Lake). Seeing preliminary results of this work the “navy research officials decided to treat their scientists' cold fusion research a little more seriously. Up to this point the cold fusion work at the navy labs had been informal - experiments were carried out in researcher' "spare time", funded by their department chiefs' discretionary budgets. But after Miles, Szpak and Boss had been at their benches for three years, they had collected enough evidence to convince those higher up the ladder to formalize their efforts.” A limited budget was allocated to continue cold fusion research.

“From the beginning, the idea was to keep things modest. ‘We put less than $1 million a year into the program,’ Nowak says. ‘Above that level, the red flags go up.’ Saalfeld and Nowak never gave the program its own line in the ONR's budget, but allotted money to it from miscellaneous funds. ‘We were to keep working and we were allowed to publish our results, but we weren't supposed to say a lot about it,’ Miles recalls. ‘Some people were worried that word would get out and it would jeopardize the navy labs' funding from Congress for other research. We didn't even call it 'cold fusion'. We called it 'anomalous effects in deuterated systems'.’ “

But research work was not easy and results were not always reproducible, as illustrated by the following description: “In July 1992, Miles received Imam's first attempt at making a suitable electrode, a palladium-silver alloy. ‘It produced nothing,’ Miles recalls. ‘Energy in was equal to energy out.’ For almost two years, while Boss and Szpak logged success after success, Imam sent Miles a steady stream of palladium alloys, and even various forms of unalloyed palladium. None produced any excess heat at all.” But things changed (in the summer of 1994) when alloyed samples of pure palladium with boron were tested. Using these new materials Miles was able to observe excess heat from eight out of nine cells. But why didn't the ninth one work? The answer came from Imam who engineered new materials. He found that negative electrode used the ninth cell was very different from those used in the eight heat producing cells. Instead of being microscopically smooth it had numerous cracks on its surface.

“A correlation between cracks and null results has been noted by many researchers, before and since. So the researchers had evidence of excess heat. They had also seen telltale evidence of nuclear reactions in the form of tritium and otherwise inexplicably large amounts of helium.” But this work had to stop in the next year. “By 1995, after watching Miles trying and failing to wring excess energy from Imam's electrodes, Saalfeld and Nowak decided to stop giving the project any more money. .....With the money gone, Szpak and Boss moved on to other projects. Miles wasn't so lucky. In 1996, Nowak left the ONR, robbing the navy's cold fusioneers of their front-line champion. Around the same time, Miles's boss left, and his replacement discontinued the discretionary funds that had been supporting the work. To make things worse, Miles couldn't find other work. ‘I couldn't get ONR funding for anything,’ he says. After failing to find new projects to take on, in 1997 Miles - with an international reputation and more than 100 publications to his credit by that time - was reassigned to work as a clerk in the stock room.”

But all this did not destroy confidence of scientists. They are still willing to resume research if it is funded. One of them wrote: “Something is going on, though, and the navy may eventually see fit to investigate it further.” In 1997 Mill was invited to participate in the Japan's New Hydrogen Energy Program. “During that time, he ran 11 experiments and three control tests. Of these 11 experiments, 10 yielded anomalous energy. These included tests that used Imam's palladium-boron blend, and three new tests of the co-deposition method. When he returned, Miles wrote papers detailing some of his results, which were published in 1999 in Fusion Technology and a year later in the Journal of Electroanalytical Chemistry and Interfacial Electrochemistry. Boss is also ready get back on board if the work is funded. And though Szpak has now retired, he still comes in to the San Diego lab to work at refining the co-deposition technique, supported on a shoestring budget that Gordon, his department chief, supplies.”

Anticipating future development scientists believe that the revival should be modest. One of them said: "If you put a bunch of money into this, you'd probably have the same result you had in 1989 - a lot of unqualified people would start working on it and we'd begin to convince ourselves again that this can't work." Clarifying this another scientist said "The worst thing that could happen to cold fusion is to make a big blip on the scientific radar screen again. [The area] needs a modest amount of funding - a few million a year with a firm, multiyear commitment - run by people who aren't political and are more interested in the science than they are in building their resumes. The energies being reported are vastly too big to be chemical in origin. But that still leaves a huge question. Where the hell is all that energy coming from?"

52) Another Summary

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J. 07043, (4/12/03)

Return to the clickable list of items

After rereading the 1997 paper of T. Muzino et al., entitled “Changes in Isotopic Distribution of the Elements on Palladium Cathode Electrlolyzed in D_2O Solution,” I decided to summarize it, and add some comments. The paper describes a standard cold fusion experiment (palladium cathode, platinum anode and the heavy water electrolyte) lasting seven days. Chemical and isotopic composition of the cathode surface revealed dramatic changes in chemical and isotopic composition. The authors, affiliated with prestigious universities and research centers, took extraordinary precautions to prevent contamination. Four analytical methods were used to analyze samples: 1) energy dispersive X-ray spectroscopy (EDS), Auger electron spectroscopy (AES), secondary ion mass spectroscopy (SIMS) and electron probe microanalysis (EPMA).

Figure 1 shows distributions of peaks detected via the X-ray spectroscopy. Except for palladium, all peaks belong to elements which were originally absent. Note that the vertical axis scale is logarithmic; the numbers represent counting rates from a high resolution (GeLi) detector of X-rays. The labels "before" and "after" refer to results obtained before and after the electrolysis. The strongest argument against contamination, as far as I am concerned, are isotopic compositions of reaction products. Like Karabut (see item # 13 at < http://blake.montclair.edu/~kowalskil/cf/ >, the authors found that isotopic distributions are significantly different from those found in our environment.

An alchemist would say that palladium, on the surface of the electrode, was transmuted into Pb, Hg, Pt, Sn, Cd, Zn, Cu, Ni, Co, Fe, Mn, Cr, Ti, Ca, S and C. But unlike medeval alchemists the authors know that transmutation of elements involes changes in atomic nuclei. They are aware that nuclear processes responsible for the above products are highly unusual; their existence conflicts with everything we know about nuclear reactions. Why are all newly produced isotopes stable? How can nuclear processes take place despite repulsive electric forces acting between the atomic nuclei? Nobody can answer these questions today. Fully aware of this S.Szpak and P. Mosier-Boss wrote: “ We should like to suggest that ‘theory guides -- experiment decides’ is a preferable approach in this area of research. . . .

Immediately after the Fleischmann and Pons announcement in 1989, the scientific community became divided into believers and skeptics. The first group reported the results of their research with enthusiasm. At times their enthusiasm overstated the significance of their results. The skeptics, on the other hand, rejected these results as a matter of conviction. One often heard argument ‘this is contrary to our understanding of nuclear physics,’ thus stating that what we know is all that has to be known.

Irrespective of the position taken by the skeptics, one cannot dismiss experimental facts. As long as data are outside the experimental errors, they must be accepted regardless of our understanding and whether or not they can be easily reproduced. The facts stated in this communication were checked and rechecked for accuracy with details given in their respective references.”

Note 1: The above quote was found in a 1997 paper, entitled "Thermal and Nuclear Events Associated with Pd + D codeposition."

Note 2:
Both papers were fetched from the IEEE XPLORE data base. They were downloaded as reports from the “32nd Intersociety, vol 2.” The report was also referred to as “Energy Conversions Engineering Conference, 1997.”

Note 3: Tadahico Mizuno is the author of a book "Nuclear Transmutations, the Reality of Cold Fusion." It can be ordered at www.amazon.com ($30 new or $16 used).

Note 4:
Suppose that four probes were deposited on our planet by creatures living somewhere else in the universe. Conditions in their place are totally different from ours. The probes landed in the same place but several days apart. The first showed a wind of 50 mi/hr blowing north, the second and the third showed no significant wind while the fourth showed a wind of 30 mi/hr blowing to the west. Should the investigators conclude that the idea of wind, formulated after the first reading, is erroneous? Certainly not. They should continue to investigate till the variable nature of winds is understood. Likewise, the irreproducibility of cold fusion experiments should be studied till the phenomenon is understood. Declaring it to be pathological science makes no sense to me.

Note 5:
I have no idea why the scientific contributions of Mizuno et al. (and many others) are usually rejected as pseudo-science. Something is not right.

53) Cold fusion and microscopic cracks

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J. 07043, (4/14/03)

Return to the clickable list of items

In reading cold fusion papers i often saw references to fusion inside tiny cracks (size 0.1 to 1 microns) existing on metallic surfaces. The claim is that strong electric fields are often generated inside the cracks (which define boundaries between grains of different materials). The field can supply deuterium ions with a kinetic energy of 10 to 100 keV. The nuclear fusion cross sections, in this energy range, are known to be between about 0.03 and 30 mb. Bursts of neutrons and tritons, occasionally detected in cold fusion experiments, are said to be produced via traditional hot fusion in tiny cracks. According to a recent paper of M.Di Giulio et al. (from the University of Leecy, Italy) production of new elements in cold fusion is strongly enhance when cracks are present. What follows is my short description of their work. The original paper was published in the International Journal of Hydrogen Energy (27, 2002 pp 527-531); its tittle was "Analysis of nuclear transmutations observed in D and H loaded Pd films."

Thin palladium films were deposited on silicon wavers. Some surfaces were rough while others were smooth. The films were then loaded with H_2 and D_2 (by keeping them for one week in chambers filled with these gasses at the pressure of six bars). The films were then exposed to the UV light from an pulsed laser (308 nm, 1 Hz), presumably to trigger plasma oscillations inside cracks. "The laser fluence was always lower than 25 mJ/cm^2 to avoid palladium ablation." Surfaces were examined by SEM (scanning electron microscope), chemical compositions were determined by EDS (energy disparsive X-ray spectroscopy). The elements found in laser-treated films were Ca, Fe, S, Zn, Ti, Cu and Cr; their distribution over surfaces were closely correlated with locations of cracks. No quantitative information about the rates of transmutation were given in the article; the emphasis is on how to create surface irregularities rather than on production of new elements.

I am primarily interested in transmutation. That is I want to end this short summary with a quote from a paper of David .J. Nagel (*Accountability in Research,* 2000. 8: p. 137) about production of new elements in cold fusion experiments. The author wrote: "Transmutations of heavy elements were reported first in 1995 when the Pd electrodes in a heavy water electrolyte became radioactive and exhibited gamma ray spectral lines appropriate to neighboring elements of Pd. Later, the coated-sphere experiments and solid-electrolyte experiments lead to reports of the generation of numerous elements across the periodic table, with many of the same elements increasing in concentration within both of the very different experiments. All of these problems, the diverse experiments and the complex results continue to make study of the field of cold fusion challenging."

54) What do critics say about cold fusion?

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, N.J. 07043, (4/18/03)

Return to the clickable list of items

In an attempt to be "objective" I decided to read and review a recent book written by a strong opponent of cold fusion, Robert Park. The title of the book is "Voodoo Science; the Road from Foolishness to Fraud" (Oxford University Press, New York, 2000). In one way this book is similar to a Russian book, "The Highwaymen of Science" written by Edward Kruglijakov (Nauka, Moscow, 2001). In both cases criticism of cold fusion is mixed with criticism of fraudulent "science," such as astrology, homeopathy shamanism and antigravity machines. Referring to these areas Park writes that the claims "are totally, indisputably, extravagantly, wrong, but nevertheless attract a large following of passionate, and sometimes powerful, proponents." Kruglijakov's book is full of similar pronouncements. In one place he writes: "How can all this be explained? Why is it that poorly educated con artists can influence the thinking of so many? There are many causes. General social upheaval and the ideological vacuum created by the abolition of old ideas led to a situation in which tired, disillusioned individuals started to believe in miracles."

It is remarkable that both authors belong to scientific establishments. Park directs the Office of Public Affairs of American Physical Society. Kruglijakov heads the Russian Academy of Sciences Committee created "to "fight pseudo-science and fraud in scientific research." The authors are highly educated scientists; I would expect them to be familiar with serious cold fusion publications, such as those summarized on my list <http://csam.montclair.edu/~kowalski/cf/>. But their criticism totally ignores recent findings and focuses on "easy targets," such as Joseph Newman or Dennis Lee. Both books expose fraud and scientific ignorance very well but their characterization of cold fusion is not correct. Many practitioners of cold fusion research are serious scientists and the field should be described in terms of recent findings, not in terms of mistakes made more than ten years ago. The cold fusion scientists who I met recently are very critical of unjustified claims and deplorable public relation practices. All of them agree that the initial announcement of the discovery was premature.

In one place Kruglijakov does refer to the findings of Karabut (see "Russian Connection" on my list). But instead of summarizing the results, and arguing against them, he simply disqualifies the data and calls them ridiculous "miracles." The author probably thinks that experimental findings inconsistent with current paradigms cannot possibly be accepted. Likewise, according to Park, cold fusion is a discredited claim that "may have little or no scientific support." I strongly disagree with Park's claim that "cold fusion is no closer to being proven than it was the day it was announced." Let me focus on this pronouncement. The situation in 1989 was summarized, for example, in the highly critical ERAB report. From a purely scientific point of view the main objections were:
1) Absence of reaction byproducts "commensurable" with the amount of excess heat.
2) Irreproducibility of "excess heat" experiments.
3) Absence of theoretical explanations

How can the work of Arrata and Zhang (published in 1997) be ignored when addressing the issue of byproducts? These authors demonstrated (in six reproducible experiments) that the amount of helium produced is commensurable with the expected energy of 24 MeV per event. Do the critics think that data reported by the Japanese are in error? Do they think the data are fraudulent? The same question can be asked about findings of Karabut et. al., about work of Mizuno et al. etc. etc. All these researchers are recognized experts (with the highest possible degrees); I don't believe they are charlatans or con artists.

It is true that experiments are still not 100% reproducible, but the situation is no longer as bad as it was in 1989 or 1990. According to Storms, much progress has been made in recognizing causes of irreproducibility. It should be clear that the lack of reproducibility can mean at least two things. Those who perform experiments may not be sufficiently qualified (not be familiar with significant nuances known to other scientists). Some influencing, but still unknown, factors are not under control of experimentalists. To illustrate this second point let me refer to electrostatic experiments. Every physics teacher knows that they are often "irreproducible." Today we say that the outcome of a demonstration depends on humidity but early investigators were not always aware of this. They probably believed that frictional electricity experiments were irreproducible. Why should irreproducibility be associated with "not being real"? It should be associated with "we are not aware of some important factors."

Let me illustrate this with something I personally experienced. Several weeks ago. I was heating milk in a microwave oven for two minutes. Then I removed the cup and inserted a cold spoon into it. At that moment I observed sudden "explosive boiling;" a clear indication that superheated milk was created. I tried to reproduce this event next day, and several days later. I used the same oven, the same cup, the same amount of milk, etc. but without success. Does it mean that my observation was not real? I do not think so. It only means that some important factors, perhaps the air temperature or pressure were different in subsequent experiments. Or perhaps the rate and angle at which the spoon was inserted into the cup were not exactly the same. After reading about hundreds of successful experiments in the area of cold fusion I am convinced that, unless all authors are liars, the reported phenomena were real. Cold fusion phenomena seem to depend on factors which are hard to identify, as indicated by Edmund Storms (see items 50 on my list).

I am not a theorist but I have read about several attempts to understand cold fusion, including the work of Nobel laureate J. Schwinger. Some researchers have emphasized the role of collective behavior in solid materials, as in the Mosbauer effect; others think that neutrons trapped in solids play an important role. It is true that these attempts have not produced a generally accepted theory, and that such a theory is needed to guide experimentalists. But its absence is not a valid argument against experimental findings. The entire field of cold fusion is still at the fact-gathering stage, a stage at which electromagnetism was before Faraday and Maxwell. Let me refer to a wise observation by Stanislaw Szpak and Pamela Mosier-Boss: "theory guides -- experiment decides." This is a preferable approach in the area of cold fusion. Rejecting scientific data that do not agree with the current paradigm is not scientific.

P.S.

What follows is an email message I received recently:

Dear Mr. Kowalski,
Help! My name is XXX XXXXX and I am a sophomore at XXXXX High School. In my chemistry class, I am doing a project on Cold Fusion. I was looking on the Internet for websites on Cold Fusion, and I came across your links to your Cold Fusion items. I was wondering if you could give me some advice or information? I would like to know what Cold Fusion is, [and] how Cold Fusion was started. . . . .

I am no longer comfortable saying that "cold fusion is voodoo-science." I am a physics teacher; how should I answer questions about cold fusion?

Can a nuclear process be triggered by a chemical process? The answer, based on what we know about nuclear phenomena, is negative. On the other hand many experiments seem to indicate the opposite. These experiments were

performed many years after the first evaluation of “cold fusion” was made by our Department of Energy. As a teacher I would very much appreciate a second evaluation of the field by a panel of competent investigators. What can one do to make this happen?

55) The Smoking Gun?

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, NJ, 07043, (4/20/03)

The discovery of the catalytic approach to cold fusion, by Case, has already been described in item 47 on my list. The description also referred to the work of McKubre et. al. who confirmed the observation of helium in spent cold fusion fuel. One of the major criticisms of Fleischmann and Pons was their inability to demonstrate presence of that byproduct. After rereading McKubre's article I want to focus on its main points. But first let me observe that McKubre and two of his coauthors are from the Stanford Research Institute. The fourth coauthor is a professor from MIT. Would Robert Park call them misguided scientists? Would he qualify their work as voodoo science? These highly qualified people have been studying cold fusion from the year in which it was discovered. Why did Park ignore scientists of that caliber and used Rendall Mills as an example of a cold fusion researcher? As far as I can tell Mills' proposals are only marginally connected with cold fusion; they are based The Grand Unified Theory book described at the Black Light Power company website < http://www.blacklightpower.com >

The article which I am summarizing here is entitled "*The Emergence of a Coherent Explanation for Anomalies Observed in D/Pd and H/Pd System: Evidence for ^{4}He and ^{3}He Production*." It was a paper presented at the 8th International Conference on Cold Fusion, Italy, 2000. Like many other publications of leading cold fusion researchers the article can be downloaded from the library at: < http://www.lenr-canr.org >. The authors begin by listing the "apparent anomalies in carefully performed experimental studies of D/Pd and H/Pd systems. Such anomalies include:

1) prompt emission of electrons and charged particles
2) unexplained heat in excess of known input sources
3) the residual presence of light elements (notably ^{3}H, ^{3}He and ^{4}He)
4) the possible occurrence of isotope anomalies in higher mass elements
5) unusual electrical conductance effects both stable and transient."

Then they describe four experiments verifying what has already been reported by other scientists -- the correlation between excess heat and accumulation of helium. Here is their descriptions of two experiments:

"2) Loading of D_2 and H_2 into Pd on carbon supported catalyst using modest gas pressures (1-3 Atm.) and temperatures (170º–250ºC). These experiments were designed to test the claim by Case to observe excess temperature and increasing 4He levels under similar conditions. Experiments at SRI were performed in sealed Nupro® 50 cc stainless steel vessels connected to a steel manifold. Periodic measurements of ^{4}He were made by direct connection to an Extrel® mass spectrometer capable of resolving the mass-4 peaks of D_2 and ^{4}He. Using information recorded from temperature sensors placed inside and outside active and reference gas cells it was possible to obtain heat-flow calorimetric information at times when the catalyst bed temperature rise was significant. . . .

4) Closed cell electrolytic loading of D (and H) into hollow Pd cathodes sealed to contain small dimension Pd-black powders. These experiments were performed to replicate published results by Arata and Zhang in which excess heat, ^{4}He and ^{3}He, were found to be associated with the electrolysis of such "double structured" cathodes in D_2O, but not in H_2O. In experiments performed at SRI accurate mass flow calorimetry was used to evaluate and compare the heat production of double structured cathodes electrolyzed in D_2O and H_2O in otherwise identical cells. ..... "

The results, illustrated on four figures, are remarkable. The authors were able to confirm the existence of the previously

observed correlation. Their quantitative results are not exactly identical with those reported by other researchers but discrepancies are not excessive. This work, based on findings of Case, Arata and Zhang, is very convincing evidence that the accumulation of helium in palladium is commensurable with the amount of excess heat. Let me end this short note with a quote from the ERAB report < http://www.ncas.org/erab/ > which discredited cold fusion in 1989.

"The initial announcement by Pons and Fleischmann exhibited the discrepancy between heat and fusion products in sharp terms..... The persistence of this major discrepancy [absence of reaction byproducts in the amount commensurable with the reported excess heat] in all subsequent experiments has led to various explanations as to how the observation of fusion products might be obscured. For example, some have suggested that in a solid the fusion energy is released directly as vibrations of the metal lattice, so that no hard radiations would be observed. In any case, this would not explain the absence of helium or tritium. Helium should be produced in about 50% of all reactions (see Table 1.1). Several electrodes from cold fusion experiments have been examined for helium, but at this writing, none has been reported. The amount of tritium directly observed in some experiments is much too small to account for observable heat. ...."

Why does the energy released in cold fusion, when helium is produced, go directly into the "vibration of metal lattice," rather than to gamma ray photons, as in D+D--> He? This question remains to be answered; the mechanism of helium production is still a mystery.

P.S. A recent publication reporting the results of a several-years-long study (downloadable from < http://www.lenr-canr.org >), by Antonella De Ninno et al., also confirms generation of helium byproducts and focuses on several new effects. Contribution of Carlo Rubia (Nobel Laureate) to this study is recognized by the authors. The title of the report is "Experimental evidence of ^{4}He production in a cold fusion experiment." How many independent confirmations are needed to convince our scientific establishment that cold fusion research is not voodoo science? I think the CF field should reevaluated in light of new findings.

56) Looks Like Technological Con Artistry

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, NJ 07043, (4/24/03)

An example of real pseudo-science was shown in item 16 on my list. It was posted several months ago. To my great surprise I found that the company is still in business. How many naive investors have they found? How much money have they collect from them? Why do people invest in devices without seeing them in operation?
The company website < http://www.genesisworldenergy.com/team.htm > is worth visiting.

In their Q&A section (December 2002) one reads that "commercially viable versions of the Edison Device currently exist, as does the manufacturing capacity to produce and assemble devices." In a more recent statement (March 2003) one reads that "Genesis World Energy has currently received proposals from governments, private organizations and individuals within 59 countries that meet the specified requirements listed in the Licensing Section." Hmm, how can this be verified by a potential investor? Important information about the company, such as names of its researchers, location of laboratories and factories, etc. is not available; it is a company secret.

One reader asked: "Is the information being written and posted on the Internet independently by critics of the Genesis effort accurate?" The answer to this question was: "No. Genesis World Energy anticipated from the beginning that certain individuals and industries would be adamantly opposed to the proliferation of the Genesis Technology and would attempt to stop its market introduction. Thus, we fully expected the dissemination of false information [for example, by scientists]. That is why the only correct source of valid information on the Genesis Project and Team is on this website." Here is what Robert Park, with whom I totally agree this time, comments on their activities.

"Genesis World Energy proposes to free the world from fossil fuel dependence by 'harnessing energy from the molecular structure of water'. The idea is deceptively simple: use electrolysis to separate water into hydrogen and oxygen and then use a hydrogen fuel cell to generate electricity. I know, you're going to say it will take more electricity to split the water than the fuel cell can generate..... The Genesis people say they assembled a team of 400 top scientists. You think these guys never heard of the conservation of energy? 'For security purposes,' Genesis explains, 'the Genesis Team has elected to disclose little about the science behind the technology. In the absence of detailed information, it is not possible to understand how Genesis' stated results were achieved. Therefore, the scientific community at large will analyze the Genesis Project based on conventional thinking.' OK, I'm busted! I've been relying on the First Law of Thermodynamics, which is about as conventional as you can get."
Quoted from < http://www.aps.org/WN/WN03/wn011703.html#2 >

Another critic of the device, John Lichnetstein, wrote: **"***What is Genesis World Energy?* People calling themselves Genesis World Energy have announced the Edison Device, which they say converts water into energy. They claim to be a private general partnership based in Idaho. You can verify for yourself that as of 2003-January-15, they are not registered in Idaho. They might be performance artists. They might be a scam. *What is the Edison Device?* It's been described inconsistently by GWE. When it was first released, it was a miracle that would liberate the world from fossil fuel dependence, a device that converts water to hydrogen and oxygen and back, extracting more energy from the conversion to water than is required for the conversion from water. This is what's traditionally called a perpetual motion machine; it's a violation of the first law of thermodynamics..... *Have there been independent tests of the Edison device?* No such claim is made. GWE claims that they have shown the device to various smart folk, but none of these folks are talking. An anonymous endorsement is uninformative..... *Who is GWE?* The Edison device design team all wish to remain anonymous..... I'm John Lichtenstein, a statistician from California. I hate to see people ripped off." Quoted from < http://slashdot.org/~chipotle_pickle/journal/21169 >

57) Hydrinos: are they really predicted by Mills' theory?

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, NJ, 07043, (4/25/03)

What should one think about BLP (Black Light Power Inc.), a company headed by Randell Mills? Unlike cold fusion, which is still a purely empirical field of investigation, his claims seem to be based on theories. And unlike the secretive company, Genesis World Energy (see item 56 on my cold fusion list), Mills does provide information about his scientists, the location of his laboratory, etc. I would very much like to know what a theoretical physicist would say about Mills' theory. With this in mind the following message was posted on Phys-L, an Internet discussion list of physics teachers:

On 4/22/2003 Ludwik Kowalski wrote:
> Randell Mills claims that the ground state of hydrogen
> (ionization energy 13.6 eV) is not the lowest possible
> energy state of the atom? How can it be that such a thing
> was never discovered by spectroscopists?

> his arguments real or are they only a camouflage for nonsense?

On 4/23/2003 XXX replied:
> As best as I can tell there is absolutely nothing to his
> claims. The people at the www.csicop.org have a short blurb
> about it written 6 years ago. Mills (who is an MD not a
> physicist) has not built any such device and is still trying
> to raise capital for his idea. Let's just look at the obvious.
> There is no solution to the basic Schroedinger equations that
> have "fractional" quantum numbers. If he is right Quantum
> Mechanics is sunk and transistors do not work.

Unfortunately, this has been the only reply. In my mind neither the Edison engine nor technologies based on hydrinos have anything to do with cold fusion. These technological claims are based on theoretical predictions unconfirmed by experiments. The cold fusion claims, on the other hand, are just the opposite; strange phenomena have been observed

but they have not been explained by an accepted theory. Referring to hydrinos, Steven Weinberg, a 1979 Nobel laureate in physics, wrote that the idea of the ground state "is a fabulously well-tested mathematical theorem. I would bet my life on it." Then he added: "of course a theory can be wrong; we don't turn a blind eye to anomalies...you don't throw away 75 years because of an anomaly you don't understand. As far as we know, quantum theory is rigorously valid. I have no idea what would replace it." These quotations were found at

http://www.space.com/businesstechnology/blacklight_power_000522.html

together with interesting comments about Mills' theory. Addressing the same subject Robert Park, (the author of "Voodoo Science; the Road from Foolishness to Fraud," Oxford University Press, New York, 2000), wrote: "His 'theory' reminded me of my thesis advisor's comment when I referred to my first scientific paper as 'a theory'. 'It's a theory,' he said gently, 'to the extent that it was done with a pencil.' Nor had Mills offered any experimental evidence for his claim." Park's book was written for general public. As a physics teacher I would like to know about specific errors, unjustified assumptions, etc. in theoretical papers of Mills and his coworkers. More specifically, I would like some help in finding out what makes the theory ridiculous.

One more aspect of this subject is worth mentioning. It has to do with the role of authority in science. Many think that scientists do not need authorities to validate experimental or theoretical proclamations. This is not always true. A scientist may not have equipment, and training, to perform a sophisticated experiment. Or s/he may have only a limited theoretical background to distinguish valid theoretical arguments from those that are not valid. It is practically impossible to be an expert in everything and, except in his or her own specialty, a scientist is essentially in the same situation as a layman. Many claims are accepted by us when several experts agree that statements are valid. Teachers of introductory courses know how to verify claims made in textbooks. But claims made outside familiar areas are often accepted on the basis of authoritative statements. Recognizing this fact professional journals often publish review articles for their readers. A serious review devoted to the last ten years of research in the area of cold fusion is needed.

P.S. Here are two pieces about R. Mills found on the Internet:

http://csf.colorado.edu/archive/sustain-l/msg00367.html
1) " . . . Dr. Randell Mills, the founder and President of BlackLight Power Company, has a prestigious academic and professional record as a scientist and inventor. He graduated summa cum laude and Phi Beta Kappa in 1982 with a degree in chemistry from Franklin and Marshall College in Pennsylvania, and went on to Harvard Medical School, where he earned the MD. degree in 1986, conducted applied research, and filed patents on several revolutionary medical technologies. Dr. Mills' graduate education also included classes in electrical engineering at MIT, which influenced him to examine certain problems with current atomic theory. .....Since 1989, however, he has devoted nearly all his energies to the development of what he has dubbed the HydroCatalysis process of liberating energy from hydrogen atoms. . . . (5/29/97)"

http://www.njo.com/business/ledger/d8b23a.html
2) Kevin Coughlin (Star Ledger (10/10/99), wrote that Mills is "misguided at best, a sci-fi con man at worst. P.T. Barnum with an F in physics, a perpetual motion machine of ego. If Mills is right, they say, then a century of quantum mechanics -- the bedrock of modern physics that has produced transistors, lasers, telecommunications -- is wrong. 'His theory is totally groundless,' says Paul Grant, a former IBM scientist now with the Electric Power Research Institute in Palo Alto, Calif. But the brickbats haven't kept private investors – including two power companies and a former federal energy official – from pumping $20 million (the company's figure) into Mills' BlackLight Power Co. Inc. They're betting he's the next Einstein, even though some admit they can't understand a word of "The Grand Unified Theory of Classical Quantum Mechanics," Mills' self- published tome. (A thousand pages for $100, at Amazon.com.) If Mills is right, they say, he will transform the world and make them all very, very rich. . . .

Mills says he's found the answer and it's chemical, not nuclear..... And no room-temperature fusion in a jar. The concept of "cold fusion" caused a sensation 10 years ago, but its promise of limitless energy hasn't panned out." Is the author aware that many scientists continue working on cold fusion phenomena? Is he aware that accumulation of helium, missing ten years ago, has been observed by several teams of researchers? Cold fusion, as I wrote above, is a set of experimental claims without an accepted theory, it is not a theory without experimental confirmations.

Scientific theories are justified by their mathematical correctness, and validated by experimental data. And what validates experimental data? Some say that laboratory data must be reproducible, and I agree with this. Others say that reproducibility alone is not sufficient, experimental data must be consistent with other data via theoretical models. I agree that consistency with other data is a desired end product of a research project. But I do not think that consistency is necessary at initial stages of investigations. Comments on reproducibility, in the area of cold fusion, can be found in items 54 and 52 on my list.

< http://blake.montclair.edu/~kowalskil/cf/ >

Experimental facts, not consistent with existing theories, should be suspected to be wrong but they should not be rejected on that basis.

Another P.S. On August2, 2003 I received the e-mail from Norm Winningstad

Dear Dr. Kowalski,
You should know that the self-proclaimed physics gurus [such as the APS spokesman, Dr. R. Park, who claims that no spectral lines of hydrogen atoms exist below 80-nm] are now in serious trouble..... If you simply substitute 1/p for "n", [in the Rydberg equations] the positive integer number of the hydrogen orbit, and let "p" be any positive integer, you get the location of the spectral lines of the hydrino. The reason the spectra of the hydrino was not see before is that it is not commonly found on earth (before Mills.) BUT it WAS seen before, but not recognized. .....The below 80-nm spectra is now peer-reviewed and published, it was done at another lab from Dr. Mills' lab (it was done in the Netherlands.) Dr. Park now needs to shut up, and other skeptics need to have the courtesy of examining the experimental results; they will all learn something new.

* * * * * * *

I replied: Dear Norm:
1) Who are you and how did you find out that I am interested in hydrinos?
2) I agree with you that experimental results are essential. And that R. Park's should examine them before making strong negative pronouncements.
3) Please supply references for the peer-reviewed publications of experimental results.
4) What would be more convincing than experimental results properly interpreted by experts? (a) Confirmation of such results by experts from other laboratories and (b) personal participation in the validation process.
5) Are you one of those who had a chance to participate? I am a physics teacher who was not able to penetrate the depth of theoretical arguments of Mills.

* * * * * *

“Dear Ludwik:
. . . I am C. Norman Winningstad, BSEE, MBA, LL.D, and I worked for the Lawerance Berkeley Laboratories early in my career, . . . The references are now on the BLP home page. The probem is (I have asked them to correct it) the papers are not marked as to what journal they are published in, which complicates the search. ..... I am a techweenie by education, and I understood what Mills was talking about. I went back to his lab, and watched it happen (^_^) But Park and Zimmerman were invited, but it was beneath their dignity, I guess, so they didn't go. But just lately, Pirelli in Italy duplicated the plasma generation tests, and they are hot-to-trot. .....I did a little digging, and I would recommend you go to the BLP web site, and click on the left on Technical Papers. Then at 2nd from the top, click on Abstracts. Then go to #1, about the NASA report. Go to # 45, which has a Journal of Applied Physics peer-reviewed article (2002) Vol. 92, No. 12, pgs. 7008-7022. #49, Journal of Molecular Structure. #62, IEEE Transactions on Plasma Science, Vol. 30, No. 2 (2002) Pgs. 639-653.

I will be the first to admit that it is frustrating to have most of the new articles listed as "Submitted" or "In Press." I assume the first means it is not peer-reviewed yet, and the second, that it is peer-reviewed, but not yet printed (*_*) You will note the list is long, largely because of the crescendo of writing lately at BLP as a result of their experimental work being fruitful, due to years of optimizing. I suspect the reason that they do not name the journals where the papers were Submitted, or where they are In Press, is because BLP experienced having papers through the peer-review process, only

to have the editor over-rule his own peer-review panel, just before printing, because it was leaked to Park and/or Zimmerman, who blew into the editor's ear about how foolish he will look, if he publishes some thing contrary to Schroedinger's Equations (^_~)”

If I had time I would ask Randell Mills, whose labs are in New Jersey, to invite me for a demo. But my priorities are about to shift toward teaching. I will keep this possibility in mind. This fellow, Norm, seems to be overexited, especially in long parts of his messages that were skipped above. He was mostly a businessman. Now he is a writer and a consultant (at $500 per hour). Did he invest his own money in Mills’es company?

58) An ongoing public debate about cold fusion.

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, NJ, 07055 (5/9/03)

A teacher from the Phys-L discussion list sent me pieces from an ongoing cold fusion debate at < http://prorev.com/ > . I am posting these pieces as an illustration. The list "owner" is Sam Smith, the author of Piece 3. He is a journalist and a politician. The pieces illustrate interest in cold fusion.

Piece 1
It's amazing to me that none of the people proposing that government spend money on CF have spent any of their own on it, nor found any venture capital -- there are billions of dollars running around out there looking for a good investment opportunity. If CF had 1/1000th of the potential that its backers claim you'd think they'd be fighting to get their money into the pot first. . . oddly, they only want other people to invest in it.

Piece 2
To the physics community, cold fusion appeared unlikely, but if true, exciting, so a rush of labs tried to replicate the P&F result. While most labs had no luck, a few had occasional and marginal success, though their results can not be verified by other labs. This is pretty much what you expect if cold fusion doesn't work. While cold fusion requires only a modestly equipped lab, judging the results of an experiment is difficult. Rare neutrino emissions, a measure of success, are difficult. Small 'excess' heat is the other prime measure of success, but as this is the difference between large energy inputs and outputs it is easy to make a mistake. A well known similar case where measurement is difficult is calculating the power carried by alternating current electricity. Problems with this have mislead good engineers, and over the years has been the basis of a bunch of perpetual motion machines. If cold fusion really worked, I would expect a reliable setup very similar to the P&F one to have been found in the initial rush of experiments. If something pretty simple sort of works and a bunch a people give it a try, some of them will hit the way of making it work. A reliable method of achieving cold fusion would be new physics, and tremendously interesting even if the energy generated was miniscule.

Piece 3:
I was a physics major at U of I, Urbana-Champaign when cold fusion was first reported, and I followed it closely for a while. Over time it became clear the P&F had done shoddy work, that it was easy to get mislead, and that the other reported successes were marginal and unrepeatable. I think the continuing interest is due to the great interest in energy generation, the relative ease of setting up a cold fusion experiment, and the capacity of people to believe what they really want to be true. [Most of what I know about science I learned in high school, but I have followed the confluence of science and politics, a problem that dates back at least as far as Galileo and is as recent as the numerous duplicative Star Wars reports done for the Reagan administration by defense contractors and universities (and their scientists) in support of the former's political agenda and the latter's budgets. As whistleblower Alric Saucier put it, Star wars was "largely a paper program producing research and development studies. The reports are a shameless waste. Multiple contractors are assigned to do the same work and then to do it again and again. As a rule, the studies are not read. They get stored at different locations outside the Pentagon until room is needed for new ones. . ." That was not just bad science, it was fraud. I was similarly attracted to the cold fusion issue because of political, rather than scientific, factors. After the initial Pons-Fleischmann experiments had proven faulty, a number of anomalies developed. Some of the media seemed to go out of its way to beat a presumed dead horse and a couple of anti-cold fusion books even appeared. The

Department of Energy made it publicly clear it wanted nothing to do with the matter.
The Patent Office refused to consider it.

Meanwhile, in other countries research continued, sometimes - as in Japan - with public monies, and some hardy American scientists kept plugging away, all gathering at international conferences notable for media absence. Even Toyota put money into the research, although the Japanese have since slashed their funding. Also in foreign lands was little suggestion that those interested in the subject belonged at Waco rather than in the lab. As one investigator put it, "In the U.S. there is a degree of envy among cold fusion researchers for their Japanese colleagues. In Japan, the debate over cold fusion is polite and scientific. Researchers are not rashly judged or branded incompetent for suggesting cold fusion could be real. Their American counterparts would like to conduct research in a similar atmosphere, without accusations and emotionalism."

The potential import of cold fusion, should it prove valid, along with the economic interests involved - including those involved in conventional energy or getting government money for other alternatives raised the suspicion that some of the opposition might not be scientific at all. The hostility seemed to go beyond skepticism and veered towards political or public relations campaigning. So the Review - in its role as a way station for the new, the imaginative, and the abused - has remained hospitable to the cold fusionists without offering the slightest guarantee that they are right. They simply deserve to have been treated a lot better than they have been. But don't trust me. You can check it out for yourself by attending the Tenth International Conference On Cold Fusion at the Sonesta Hotel in Cambridge, MA in August. Some professor at MIT is the chair. He can probably explain it better than I can.

59) To be published in a local newsletter

Ludwik Kowalski
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ
(May 19,2003)

In March 1989, two reputable chemists, Fleischmann and Pons, announced the discovery of an unexpected heat-generating phenomenon at the University of Utah. This effect, labeled “cold fusion,” was immediately investigated by many researchers, not all of whom were able to confirm it. A controversy ensued; some scientists became skeptical about the reality of cold fusion while others continued to study it. A highly unusual formal investigation of cold fusion, initiated by the US Department of Energy, took place several months later. The report resulting from the investigation was mostly negative and, like most people, I accepted its conclusions. But today, thirteen years later, I am no longer comfortable saying that “cold fusion is voodoo-science.”

What caused me to become more open-minded? It was the 2002 International Conference on Emerging Nuclear Energy Systems (New Mexico). Several papers presented there were devoted to cold fusion research. After the conference I gathered a large number of recent cold fusion papers (available at www.lenr-canr.org) and several books devoted to the phenomenon. Critical evaluation of that material was facilitated by my nuclear physics background. Using the Internet I was able to communicate with scientists who have been studying cold fusion since its premature announcement by Fleischmann and Pons. I was highly impressed by what I read, and by the credentials of many authors. A Nobel prize laureate, J. Schwinger, for example, was trying to construct a theoretical model of cold fusion in the last year of his life.

Conducting research in cold fusion became very difficult in the US after the scientific establishment (NSF, DOE, leading journals, etc.) declared the field pseudoscientific. Financial support for research was cut and many journals no longer offered peer review of submissions in the discredited area. Despite these difficulties some Americans continued to explore the field. Very significant discoveries were made by them, and by scientists from other countries, such as Japan, Italy, Russia and France. It turns out that cold fusion is very complex; no generally acceptable theoretical model has been advanced, as far as I know, to explain the experimental data. The absence of an accepted theory is a great weakness. The term cold fusion usually refers to two kinds of observed phenomena: generation of unexpected heat, and occurrence of highly unusual nuclear reactions. Practical applications of these effects may be possible in the future; speculating about them seems to be premature.

The major criticism of cold fusion studies is that results are not always reproducible. Initially only about 50% of researchers were able to confirm generation of excess heat. The situation is much better today but one still cannot be sure that all experimental results obtained in one laboratory will be confirmed in others. The outcomes of experiments seem to depend on difficult to identify conditions, such as presence or absence of some impurities (at the ppb level) or surface irregularities of metals. It is remarkable, however, that perfect reproducibility in a single laboratory has often been reported when essential materials, such as palladium, originate from the same manufacturer and from the same production batch.

In my opinion, the absence of qualitative reproducibility is a clear indication that the cold fusion field is still a mixture of art and science. But this is not sufficient reason to declare it pseudoscientific. Cold fusion scientists trying to make their field scientific should be supported by government agencies (such as NSF, DOE, etc.); why should they be treated differently than scientists working in other fields? Their papers should not automatically be rejected by our leading journals; they should be given the same chance to be published as papers in other areas of science and technology. How can this be accomplished? If it were up to me I would suggest another formal evaluation of the entire cold fusion field

by a group of appointed experts. That group would visit existing cold fusion research centers, study the reports and participate in experiments. Then, after a year or two, it would issue a report based on data which were not available to the first investigating team.

It is unprecedented that an area of research, conducted by recognized experts, has been officially declared an outcast of mainstream science. Are experimental cold fusion data fraudulent? Are we dealing with a mass-scale self-deception involving hundreds of scientists in several countries? It is difficult to answer such questions; they would be totally irrelevant if the cold fusion field were rehabilitated. An authoritative report by a group of experts would help teachers deal with this unusual situation in the history of modern science.

In order to reach my own conclusion I plan to go to the 2003 International Cold Fusion Conference (Massachusetts). Hopefully, this will result in an invitation to participate in an essential experiment conducted by a recognized expert. As a nuclear physicist I would seek an invitation to confirm the reality of a nuclear transmutation process due to a chemical process. Witnessing one such phenomenon would be sufficient for me to be able to claim that cold fusion is not a self-deception or fraud. For the time being I will continue studying papers available over the Internet and sharing with others what I learn. Feel free to examine my items at http://csam.montclair.edu/~kowalski/cf/

60) Alchemy; comments on two papers

Ludwik Kowalski (kowalskil@mail.montclair.edu)
Montclair State University, Upper Montclair, NJ 07043

The 1996 Japanese paper of T. Mizuno, T. Ohmori and M. Enyo, downloaded from the www.lenr-canr.org, is worth reading; it shows evidence of nuclear transformations taking place in a Pd-Pt-heavy water electrolytic cell. Several analytical methods were used to demonstrate that isotopes of many elements (mass numbers from 6 to 220) were deposited in the Pd cathode during its one-month-long operation. This is highly unusual nuclear alchemy. In the introduction to the paper the authors claim that the accumulation of elements in the cathode can not possibly be due to contamination because, in many cases, the isotopic composition of reaction products is highly unnatural. For example, natural chromium is known to be 4.3% ^{50}Cr, 84% ^{52}Cr, 9.5% ^{53}Cr and 2.4% ^{54}Cr. But the chromium found in the cathode was 14% ^{50}Cr, 51% ^{52}Cr, 2.4 % ^{53}Cr and 11 % ^{54}Cr. The percentage differences are extremely significant; natural variations of abundance of chromium isotopes is known to be less than 0.003%.

Similar observations were made, at about the same time, by two American scientists:
G. H. Miley and J. A. Patterson. Their paper can also be downloaded from the above mentioned www.lenr-canr.org web site. The authors analyzed composition of elements accumulated in a very thin Ni foil used in an electrolytic cell. They wrote: “Following a two-week electrolytic run, the Ni film was found to contain Fe, Ag, Cu, Mg, and Cr, in concentrations exceeding 2 atom % each, plus a number of additional trace elements. These elements were at the most, only present in the initial film and the electrolyte plus other accessible cell components *in much smaller amounts*. That fact, combined with other data, such as deviations from natural isotope abundance, seemingly eliminates the alternate explanation of impurities concentrating in the film.”

Analytical methods used to detect and analyze the accumulated elements in these studies were: secondary ion mass spectrometry (SIMS), Auger electron spectrometry (AES), energy dispersive x-ray (EDX) analysis, electron probe micro analyzing (EPMA), and neutron activation analysis (NAA). Let me describe these techniques briefly.

SIMS: A sample under investigation is placed in a vacuum chamber and high-energy ions are fired at its surface. Known as ‘primary’ ions, they penetrate the near-surface atomic layers and set up chains of collisions between surface atoms. This results in releases of ionized (secondary) atoms from the exposed material. These atoms are analyzed in a mass spectrometer. Surface imaging is possible by focusing the primary ion beam on selected spots of a sample. The depth profile of trace elements concentrations can be obtained by using the ion beam sputtering, that by removing thin layers of material.

EDX: A sample to be examined is used as an anode of an X-ray tube; it is bombarded by electrons whose energies are between 10 and 20 KeV. The characteristic X-rays are analyzed with a high resolution Li drifted silicon detector. The method is used to study chemical composition of materials at the depths of up to microns. The sample can be scanned to perform surface imaging.

AES: A sample under investigation is placed in a vacuum chamber and bombarded by a beam of electrons whose energies are sufficient to ionize atoms. This results in the emission of characteristic X-rays, as in the EDX, and in the radiationless deexcitation process producing Auger electrons. The energy spectra of these electrons are analyzed to identify individual chemical elements and to determine their concentrations near the surface. Note that Auger electrons generated in deeper layers do not escape from samples. Chemical surface imaging is possible by scanning the surface with the focused beam of electrons.

EPMA: It is essentially a scanning electron microscope designed and optimized for X-ray analysis of elements from small areas. An X-ray spectrometer is used to identify elements, scanning is used to perform chemical surface imaging.

NAA: A sample under investigation is first exposed to a beam of neutrons, usually in a nuclear reactor. It is then analyzes with a detector of nuclear radiation. The nature of radiation is indicative of the average chemical composition of the irradiated sample.

The instruments used are sophisticated and only highly qualified scientists are able to use them. Pseudoscientists would not know what to do with such instruments, or how to describe observations correctly. And, yet, the entire cold fusion field is often said to be pseudoscientific. By the way, the authors of the above two articles are affiliated with highly reputable research centers: Department of Nuclear Engineering of Hokkaido University, Catalysis Research Center of Hakkaido University and Fusion Studies Laboratory at the University of Illinois. They are veteran scientists and recognized authorities in several disciplines. On what basis can their research be disqualified as pseudoscientific?

61) How will cold fusion be remembered?

Ludwik Kowalski (May 21, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

I have no doubt that cold fusion will be remembered as an unusual event in the history of science. Hundreds of qualified researches (Ph.D.s, publications, recognitions, etc.) are practically blacklisted. In most cases discoveries are debated among scientists without formal investigations initiated by government agencies. Without interventions debates often continue for as long as necessary. In some cases discoveries are eventually validated by other scientists; in others they are shown to be wrong. Occasionally debates linger without leading to definite conclusions; then they die due to lack of interest. But that is not what happened in the case of cold fusion. Less than one month after the discovery was announced the US Department of Energy prompted a formal investigation. In the request to investigate, dated April 24, 1989, one reads:

“In recent weeks, there has been a great deal of interest in the prospects for ‘cold fusion’ based on experiments at universities in Utah and subsequent experiments performed elsewhere. At present, the apparent observations of cold fusion and significant quantities of energy from this phenomenon are being investigated extensively. Because of the potential benefits from practical fusion energy, I request that the Energy Research Advisory Board (ERAB) assess this new area of research. Specifically, I would like the Board to:

1. Review the experiments and theory of the recent work on cold fusion.
2. Identify research that should be undertaken to determine, if possible, what physical, chemical, or other processes may be involved.
3. Finally, identify what R&D direction the DOE should pursue to fully understand these phenomena and develop the information that could lead to their practical application. I request that the Board provide an interim report on the first item by July 31 and a final report on all items by November 15, 1989".

I think that addressing the issue of “practical applications” was premature and that the special investigation of cold fusion by an appointed board was a mistake. Nine months after the initial announcement at the University of Utah the board issued its final report. In the executive summary of that report one reads:

"The Panel concludes that the experimental results on excess heat from calorimetric cells reported to date do not present convincing evidence that useful sources of energy will result from the phenomena attributed to cold fusion. In addition, the Panel concludes that experiments reported to date do not present convincing evidence to associate the reported anomalous heat with a nuclear process".

This was a correct summary of the situation in 1989. But why did the announcement of Fleischmann and Pons trigger a special investigation? The answer has to do with highly unusual circumstances at the University of Utah described in many books. The president of the university wanted to establish an extraordinary research center to harvest benfits from an unconfirmed discovery. In the same executive summary one reads:

"The Panel recommends against the establishment of special programs or research centers to develop cold fusion. However, there remain unresolved issues which may have interesting implications. The Panel is, therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system."

In other words, the final recommendation was to treat the announced discovery in the same way as any other scientific claim, to continue studying the phenomenon in different research centers. But that is not how the report was interpreted by our scientific establishment, that is by directors of research granting agencies and by editors of major scientific publications. For them the report was a red light to stop supporting cold fusion research and to stop publishing results of scientific investigations in that area. They saw the report as an authoritative pronouncement that cold fusion was

“voodoo science.” This accusation is still used today.

Three reasons for skepticism about cold fusion were enumerated in the report. They were: a) irreproducible data on excess heat, b) absence of expected nuclear reaction products, and c) conflict with the existing theory of the so-called “nuclear tunneling” effect. The report shows that nuclear generation of heat, at the level of 1 watt, must be associated with between 10^{11} and 10^{12} reactions per second. It means that an electrochemical cell generating 1 watt of excess heat should produce approximately 10^{16} reaction products, such as ^{4}He. No evidence for the accumulation of helium was available when the report was written. But the situation today is very different; several researchers have reported accumulation of helium at the expected rate.

Excommunication of researchers on the basis of what they are investigating is unprecedented in the history of science. Two different scenarios can be anticipated. In the first scenario cold fusion is not validated (even after considerable efforts to demonstrate its reality). In the second scenario the reality of cold fusion is finally accepted by the entire scientific community. In one case one would have to explain a strange phenomenon of long-lasting self-deception involving hundreds of scientists in many countries. How do we know that the phenomenon of self-deception is not more common among scientists than we are willing to admit? In the second case a long-lasting conflict between scientists and administrators must be explained. What are the causes of this conflict? How does it differ, for example, from the conflict between geneticists in the Soviet Union and communist ideologists of that country?

62) Scientific American and cold fusion

Ludwik Kowalski (May 22, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

A letter to the editor of Scientific American was sent Edmund Storms in November of 2002. That letter has not been published. Today I downloaded the unpublished reply, (available at http://www.lenr-canr.org) and the correspondence it triggered. The extracted pieces can be used by those of us who discuss the issues of "science and society" while teaching physics. What follows are: Storms' letter to the editor, the unpublished reply of the editor, quotes from other correspondence, and my short comments.

Storms' Letter:
Dear Sir: Your analysis in the December issue about why science is neither respected nor understood by the general public I found to be very much to the point. Those occasions when science accepts claims that are later found to be false clearly give science a black mark. Unfortunately, in an effort to avoid such embarrassment, science also rejects claims that are later found to be true. I ask you, which is the greater threat to science and mankind, accepting a claim that can have no possible benefit or rejecting a claim that can have great benefit?

I could offer many examples of how good ideas have been rejected in the past, but I would like you to consider one very important claim that now has almost universal rejection, yet is supported by a growing body of data. As a scientist, I was trained to judge the reality of nature from good data based on replicated experiments. Yet, I find that the scientific community increasingly bases what is real on the opinions of a few respected journals and academics using theoretical arguments, regardless what is being discovered by other scientists operating in the real world. How is the general public expected to respect science when it does not follow its own stated rules of evidence?

The discovery I would like to use as an example of this double standard is what is called LENR or low energy nuclear reactions. This has also been given the very inaccurate name of cold fusion, a name that now causes rejection and ridicule. This ridicule comes from people who have no understanding about what is now known, yet their opinions are accepted as fact. Is this the way science is supposed to operate?

If you wish to be true to your stated wish to make science more respected, I suggest you educate yourself about this important phenomenon by reading information available at www.lenr-canr.org. There you will find over a thousand publications that support the reality of such anomalous nuclear reactions, as well as several reviews in full text that answer important questions raised by skeptics in the past. Serious scientists rejected "cold fusion" in the past for good reason. These reasons no longer apply. If science cannot correct a past rejection, then what good is the scientific method? Can anyone respect a scientist who cannot change his/her mind after being presented with better data? Respectfully, Edmund Storms, Ph.D.

A Response from the Editor of Scientific American, John Rennie:
Dear Dr. Storms: Thank you for your email proposing that Scientific American reevaluate the status of LENR-CANR research and consider publishing an article on the subject. As you suggested, I did look over a number of the offerings at www.lenr-canr.org. Unfortunately, I still don't see evidence in those papers, or in the mainstream physics literature, that LENR-CANR has achieved any significantly new level of credibility in the eyes of the general physics community. The site does point to a large number of publications that ostensibly offer evidence of the phenomenon, but sheer numbers of papers is not sufficiently compelling--as I'm sure you know, even the creationists can point to thousands of

"publications" and "scientists" seemingly supporting their position.

I noticed that the LENR-CANR site, on its page appealing to readers to "help spread the word" about the phenomenon, described Scientific American as having "gone far out on a limb opposing cold fusion. They, along with the leaders of the American Physical Society and the Department of Energy, have made their institutions into bastions of opposition to cold fusion." We at SciAm don't feel that we've gone out on a limb in criticizing cold fusion harshly in the past. As for our being a bastion of opposition to it, I don't think we have an intractably committed position. If LENR-CANR can be demonstrated satisfactorily for acceptance by the physics mainstream, we would be more than happy to publish more favorable articles about it. Your problem starts with establishing more credibility in their eyes, not ours.
Sincerely, John Rennie

Comments:
Referring to the above, Jed Rothwell (the manager of the lenr-canr web site) wrote: “Rennie has dismissed 2,000 papers, including research from laboratories such Los Alamos, the Naval Research Laboratory and Mitsubishi Heavy Industries, mainly by equating these papers with creationism. Waving your hand and saying that "X is like creationism" does not make X resemble creationism. Cold fusion is an experimental finding, which is completely unlike creationism, or actual evolutionary theory, for that matter. It is not based on theory or an interpretation of the fossil record, but rather on long-established laboratory instruments and procedures in calorimetry, mass spectroscopy and so on. The only way to disprove cold fusion is to find technical errors in the techniques that are applied by specific cold fusion researchers.”

Only highly trained scientists using expensive equipment are in a position to validate cold fusion claims. We read their papers and form our own opinion. This fact should be recognized; the situation was very different one hundred years ago. Neither editors of Scientific American, nor we, physics teachers, can perform experiments with sophisticated mass spectrometers in ultra-clean labs. In this new situation the role of a journal like Scientific American becomes even more important than in the past. I have no idea why Storms’ letter was not published. The author is a recognized authority in nuclear chemistry, a research veteran from Los Alamos, one of the best nuclear technology laboratories in the world. Why was he silenced by John Rennie?

Responding to Jed Rothwell the editor of Scientific American wrote “the people you need to convince about the scientific credibility of cold fusion aren't journalists. They're professional physicists who review submissions for respectable technical journals. If you can convince mainstream scientists that LENR-CANR is real and significant, magazines like Scientific American will drop into line.” In other words, he is saying that Scientific American is not a technical journal; its decision to silence a high caliber scientists was bureaucratic rather than scientific. I can understand this. But I do not think that Storms’ letter would do any harm to the general public. On the contrary, it would promote interest in science.

63) Jed Rothwell's publication

Ludwik Kowalski (May 23, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

1) Jed Rothwell is one of those who manage the lenr-canr.org list. Last night I sent him a message making the following suggestion: ". . . My sabbatical project devoted to cold fusion will culminate just before the beginning of the academic year. It will be my participation at the 10th ICCF. During that conference I would like to have a chance to meet and speak with major CF researchers. I also want to write an article about that conference. Perhaps it will be published somewhere; if not it will be shared as another item on my web site. With this in mind I would like to suggest that conference organizers collect statistical information about participants. How many of them (percentage) hold Ph.D. degrees in science and technology? How many . . . I think that information of this kind is worth collecting and sharing. It will show how cold fusion proponents differ from pseudo-scientists. The best way to collect such information, I think, is to prepare an anonymous form and to send it to each person who registers. . . .

Responding to the above Jed wrote: "There will be few people at the conference. Most researchers have retired and are too old or too poor to attend. How many of them (percentage) hold Ph.D. degrees in science and technology? 100%, I expect. I do not know any who do not have a Ph.D.. How many of them have published at least ten papers in their specialties? All of them, I expect. All the ones I know have. People like Bockris and Fleischmann literally wrote the book on the subject. I mean the authoritative textbooks. They are all senior people, because young people would never be allowed to do CF. How many were affiliated with national labs? Not so many. Storms, Miles, Srinivasan and a few others. Most are from universities. How many were university professors? Nearly all, including Miles, who also did a stint at China Lake. How many were research project directors? etc. etc. I wouldn't know. Fleischmann and Bockris were.

2) Jed also referred to a paper he presented at the 1999 conference, and modified this year. It can be seen at http://www.lenr-canr.org/acrobat/RothwellJcomparison.pdf. Let me comment on some points of that paper.

a) Problem of age: Jed wrote: [in the past] "young scientists have made most new discoveries.....They have the instinct to explore, and strike out for new territory. This is considered the natural order of things, and perhaps it is, but it is also a cultural construct. Unfortunately, the culture of science has changed. We punish failure. Research is too formal. Fun in the laboratory is discouraged. Young people have grown up with this system and know no other. Nowadays, old scientists are in the vanguard. They have tenure. They came of age in a more dynamic, liberal era when mistakes and adventures were encouraged, and progress was in full flood. Young scientists are afraid to step out of line. Controversial research will jeopardize their careers. Too much scientific funding is controlled by policymakers in Washington and science journal editors who demand allegiance to established theory."

It is true that exploring cold fusion is a risky business for a young scientists. Who wants to be branded a pseudo-scientist after investing several years in serious investigation of an abnormal phenomenon? Who wants to enter a field in which research grants are not available? Only people with tenure, or retired, can afford to be active in an officially condemned field. That is why another official evaluation of cold fusion is urgently needed.

b) Problem of demonstration device: Jed wrote: "[Eugene Mallove] and I tell scientists to put aside their theories, stop trying to improve their calorimeters, stop trying to improve reproducibility for the time being, and concentrate on a public demonstration instead.....Many scientists respond to our suggestions with hostility, because they do not understand our strategy. They think we are denigrating theory, and belittling the need for rigorous experiments and better calorimeters. We say first things first: get the funding, and then go back to your research. Many scientists dismiss

this as grandstanding or a publicity stunt."

I agree that it would be extremely useful if, instead of exploring many different aspects of cold fusion, the effort of many could be focused on one aspect, such as accumulation of tritium, or emission of totally unexpected alpha particles. A reliable working device demonstrating a single abnormality would convince skeptics that at least one claim of cold fusion researchers is real. Why is it that no such device has been produced in the thirteen years since the original announcement? Limited financial support in the US is only a small part of the answer, I think. Somebody will answer this question in the future.

My trip to Salt Lake City (see items 44 and 45 on this list) was triggered by a desire to produce such a demonstration, at least for physics teachers and students. Unfortunately, the attempt was not successful. At least one claim made under the cold fusion banner was shown (by the initial investigators themselves, with my participation) to be premature. This claim, as far as I know, did not undergo the scrutiny of the peer-review process. Would I be able to construct a device based on a claim made in a peer reviewed article? Which claim should have been chosen if chices were available? How many "failures to qualitatively confirm a claim" would be sufficient to discredit the entire field? Is it too late to ask such questions at the next cold fusion conference? It depends on how many active cold fusion researchers will participate. Not too many, according to Jed.

c) On cycles in support for science: Jed wrote: "generational role reversal is one reason we got into this mess. Another is that science happens to be at a low ebb. It is going through a conservative, uncreative phase in which theory overrules experiments, talented young people ignore science, and experts go around saying this is the twilight of the scientific age. I think science is cyclical, like the stock market. An upsurge begins when a dramatic improvement comes along. Success follows success; excitement causes more excitement. Society rewards the enterprise with bigger budgets, more money. Eventually the process gets out of hand. Too much success carries the seeds of future failure, breeding smug satisfaction, hubris, bloated budgets in science, and irrational exuberance in the stock market. Giant projects like the hot fusion program and the supercollider are botched; the public loses faith, budgets are cut, morale plunges. We reach a low ebb, a crisis. The crisis leads to self-examination, house cleaning, renewal and revitalization, and the cycle begins again."

That is an interesting observation. But is it correct? In the last two hundred years scientific progress was gradual, not cyclical. It was nothing like stock market fluctuations which tend to repeat themselves every ten years or so. I am not aware of similar cycles in physics. But perhaps it has to do with the scale of operations in science; in the past experiments were much less expensive than they are now. How long will scientific progress cycles be? Jed ends on an optimistic note; he writes: "I hope we succeed in my lifetime. Regardless, I have faith that science will recover, and mankind's adventures will begin anew." What is the basis for such optimism? It seems that a generation of cold fusion pioneers is leaving the stage without producing natural successors. What could have been done in ten years may take a century to accomplish in the future. One good thing is that a large fraction of reports describing what has been done is gathered in one place -- the library at the http://lenr-canr.org site.

64) Two kinds of excommunication

Ludwik Kowalski (May 24, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

William Beatty, a subscriber to Phys-L (a discussion list of physics teachers) sent me personal comments on recently published < http://lenr-canr.org/AppealandSciAm.pdf > correspondence with editors of Scientific American. William added: “feel free to use my message for anything you wish.” I decided to show it below as an appendix. In my opinion the issue of cold fusion can be solved only by competent scientists who perform experiments and discuss their meaning. Political statements, like William’s comments, and like some of my own items, are significant in the context of the issue of “science and society” rather than in the context of “validity of claims.”

But science and society topics are profound and worth addressing. One of them attracted my attention recently; it was the “excommunication of genetics” by Stalinists. At first I simply wanted to compare two kinds of excommunication, that of cold fusion in the US and that of genetics in the Soviet Union. But then I started reading about mechanisms of control of science by ideologically motivated “state apparatus.” I think I will continue writing about this in the future. (Even cybernetics was at one time condemed in the Soviet Union as pseudo-science: “psevdo-nauka na uslugakch americanskovo imperialisma”). Here is a very interesting Internet reference (authored by a Russian researcher, Kirill Rossiyanov):

http://eserver.org/cyber/stalin.txt

I did not know that Stalin was personally involved in editing Lysenko’s pseudo- scientific publications. By the way, those accusing geneticists of being pseudo- scientists (and class enemies) are now universally condemned as charlatans. Here is an intersting quote about genetics from the Soviet Encyclopedia (1950).:"...gene is mythical part of living structure which in reactionary theories like Mendelism-Veysmanism-Morganism determines heredity. Soviet scientists under leadership of Academician Lysenko proved scientifically that genes don't exist in nature."

Appendix (message from William Beatty):
[Correspondence with Scientific American is] VERY interesting. He [the current editor of the journal] seems to base his opinion of LENR only upon what others think; others who very probably have never read the papers. He should be basing his opinion on his own examination of *both* sides of the controversy... and yet he won't go and read the papers himself? Bizarre. Perhaps this a case of "my mind is made up, so don't bother me with evidence found later!" Or perhaps he's waiting for OTHER magazine editors to publish articles about the positive evidence before even questioning his own position. If so, it's bizarre for a journalist to have such an attitude, and triply bizarre for anyone associated with science.

Well, New Scientist had their short article out in March. Heh. Perhaps this just proves that New Scientist staff is incompetent? If so, then that's a classic example of the "experimenter's regress" problem. If we become certain that LENR doesn't exist, then when Schwinger and Storms and McCubre later present positive evidence for it, this is not evidence, instead it is "evidence." In other words, it just proves their own incompetence. Since we know that LENR is bogus, all the papers supporting the phenomenon are seen as powerful evidence of experimenter incompetence. In that case the reliability of the labs reporting a replication mean nothing. Since we know that LENR is bogus, then positive replications are demonstrations that those labs are incompetent. Note that no amount of positive evidence can *ever* be convincing. A pre-existing conviction that LENR is bogus acts as a mental filter. All positive evidence is seen as corrupt, and then is rejected unread. This causes the negative evidence to build up and reinforce the initial judgement, but the positive evidence does not.

But where did such a pre-existing conviction come from? In science it's wrong to first adopt a viewpoint and then to use the selection of evidence in order to support that viewpoint. Politicians do it. The legal system is based on it. Science is totally different: a bend-over-backwards search for the truth rather than a defense of a an existing position during a debate. If one claims to be scientific, yet also adopts a position not based on evidence, then that is pseudoscience. It is a particular form of pseudoscience known widely as "Cargo Cult Science." One essential element is missing: the no-holds-barred search for truth.

This illustrates that it's enormously important for science workers to remain tenative and unprejudiced. If they fail to do this, then they'll start using self-persuasion tactics. To read only the material which supports their position, while at the same time refusing to read material written by opponents, that's a blatent example of self-persuasion in action. Mr. Rennie has apparently fallen into this trap. I could be mistaken though. Has he read the several books which support LENR? Or does he only read material which supports the anti-LENR position? If the latter, then he's involved with Cargo Cult Science.

Why would anyone ever adopt a firm position and start selecting evidence? One reason is ridicule. It's a known phenomenon in sociology. Once a person has ridiculed a particular concept, that person is trapped. They've surrendered their objectivity and their self-image is on the line. A huge conflict of interest arises because, if their ridicule was wrong, it's an embarrassing error of major proportion, and they've opened *themselves* up as a target for ridicule. Once such a conflict of interest exists, only an overwhelming amount of contrary evidence can ever sway them into reexamining their position. The practice of ridicule very often leads to a firmly closed mind, so scientists should avoid such behavior at all costs.

One major mistake he made: saying that he needs no justification for his position. Totally wrong. His position is not proper science; he's not reviewing both sides of the evidence while calmly revising his opinion when new evidence comes in. Instead he takes a stance of *active disbelief*, even hostility, then refuses to examine evidence which might damage this position. Strong levels of belief and disbelief BOTH require detailed justification. The only position which doesn't require justification is the scientific one: refusing to make judgements when evidence is lacking. He certainly hasn't refused to make judgements. Yes, it is up to the LENR researchers to present evidence, it is not up to the scientific community to disprove unsupported claims. But his position is nothing like that of a scientist. Instead he mysteriously "knows" that LENR is bogus, and when LENR researchers present evidence, he bad-mouths it and refuses to inspect it. I wish he had simply cleared up the mystery in his letters to Jed. On what is his judgement based? Perhaps he wants to hide his reasoning because it will fall apart in the light of day. Perhaps it's from the following. If we're to actively disbelieve the LENR papers, on what should we base our disbelief?

1. We all know that only Pons and Fleichman presented positive results, and none of the attempted replications produced any similar effects. (Wrong, as shown by the briefest inspection of the long list of research papers.)

2. The rest of the scientific community knows that LENR doesn't exist. That many smart people can't possibly be wrong. This includes the editors of other major journals. (Bad move. This is like reviewing a book by talking to lots of other people who never read it either. T. Gold at Cornell calls this "the sharpening of opinion in a field, leading to the apperance that the problem is solved." Where is the large group of experts who have actually read any of the positive results? Do they even know that the papers exist? R. Feynman had harsh words to say about this sort of pseudoscience, re. the parable of the Emperor's Nose.)

3. Nobody offered a mechanism whereby fusion can occur at such low energy. (Bad reasoning. Galileo's whispered response shows the great flaw in the above thinking: "and yet it moves." Galileo didn't propose a mechanism. Science doesn't insist on knowing mechanisms before accepting evidence! What if this wasn't the case? This would mean that the scientific community of the time should rightly have turned their backs on Galileo, only to embrace the heliocentric viewpoint after Newton proposed a mechanism fifty years later. No! Observations don't magically become real only after a theory is later developed to explain them.)

4. Pons and Fleichman spent all that money, yet where's the fusion- powered home furnace? (Bad reasoning. Here's an analogy to illustrate. What if the scientific community had ridicule Becquerel's crazy claim that mysterious rays were

emitted by a common mineral called pitchblende? Ridicule was a danger, since he's proposing an instance of a perpetual motion machine. Fortunately his claim was trivial to reproduce. But imagine what might have happened if it wasn't. In that case, should his colleagues reject evidence on the grounds that nobody is unable to build a uranium- powered furnace in 1910 or 1920? Obviously not. We shouldn't reject LENR claims while while requiring that all new phenomena be easy to harness and engineer. And also note that Bequerel committed a high crime: he proposed no airtight theory nor identified a sensible mechanism when reporting his evidence. His evidence triggered a decades-long search for a mechanism. The LENR papers did not. Ask yourself why, then go out and find a solid answer.)

6. Only crackpots come out in support of LENR. (Wrong. Before his death, Julian Schwinger was a supporter on the theory side. SRI and NRL reproduced the phenomenon and recommended that studies continue. So did one of the country's top electrochemists J. O. Bockris. And on the public information side, Sir Arthur C. Clarke has come out as a major supporter. Ah. But because of "experimenter regress", if we decide that LENR is bogus, this just means that these people are all fools. #6 above is circular reasoning: only crackpots support LENR because anyone who supports LENR is defined as being a crackpot.)

7. If LENR is real, then Alchemy really exists! We'd have to rewrite everything we know about chemistry in the everyday world! (Alchemy is blasphemy, and LENR supporters are heretics? In science, ever it was thus: most revolutionary discoveries were blasphemy. Continental drift is the poster child for this. The above isn't an argument against LENR, instead it's a complaint that LENR, if real, will trigger the next major scientific revolution. Yes, we all knew this.)

8. Pons and Fleichman saw neutrons. Then they didn't. And the neutron output was vastly too low to explain the excess heat as having nuclear origin. Then they saw gammas at one energy. When someone showed that the energy was wrong for that sort of reaction, their next paper showed the curves moved to the right place. Doesn't this prove their incompetence? (Maybe, but maybe also it demonstrates the pressures and rushed publication of the times, and demonstrates a trial and error process of discovery which always exists but is usually hidden behind a polished research paper. Only their initial results, the thermal results, stood the test of time, and it was only later that other 'nuclear ash' such as He4 and Tritium were measured and found.)

9. Major labs showed that LENR doesn't exist. That's what led to the ERAB report which condemned the whole affair. (Yes, but this falls into the "experimenter's regress" problem: if we know that LENR is real, then when major labs cannot replicate yet a few individuals succeed, then perhaps it means that the major labs didn't call up Pons/Fleichman and ask about the various techniques needed for success. Yet if LENR *is* bogus, then it means that the major labs did perform the experiment correctly after all, and anyone announcing a successful replication has made a major error. Which position is right? We cannot know, since we would first have to know in advance if LENR is real! In other words, in order to properly judge evidence, in order to know if LENR is real, we have to first know whether LENR is real. That's the experimenters' regress.)

10. The Japanese poured huge amounts of money into LENR research. Then they gave up. If LENR is so real, why didn't a well-funded program demonstrate this? (Good question. It had better not be rhetorical. Why did the Japanese effort fail? I'm not familiar with the issue myself. There could be many answers, so we'd better investigate and not simply take it as proof that LENR is bogus. Perhaps the project was bogged down by politics? Strapped with the sort of active hostile disbelief so prevalent in the USA? Bad luck in using palladium from sources later proved to contain unknown contaminants? Refusal to contact Pons/Fleichman or other successful experimenters to find out the needed techniques? Or perhaps it was a competent demonstration that LENR doesn't exist. Further info is needed.)

11. If LENR is real, where is all the evidence in support of this position? (It's at http://lenr-canr.org Ah, but anyone who finds positive evicence for LENR has simply revealed themselves to be a crackpot? By definition, that website contains papers written by crackpots with scientific credentials? So it would seem, but only if we adopt the initial bias that LENR is bogus.)

OK, so far I see no reason for adopting a stance of active and hostile disbelief. Perhaps Mr. Rennie will wish to submit some info which will cause me to take his position. Jed's article is now in a public place. In my opinion it looks pretty bad that Mr. Rennie can't instantly give clear and convincing reasons why he has made such a firm judgement that

LENR is nothing but a mistake. If he reads this, perhaps he can replace my above list with something sound.

Voodoo science in Russia today

Ludwik Kowalski (May 26, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Kruglyakov's book about pseudo-science in Russia today has been mentioned in one of my earlier items. I read it in Russian, after the book was sent to me by Karabut. Today I found a good English summary on the subject at:

http://www.csicop.org/si/2002-07/dangerous.html

It is a paper published by Edward Kruglyakov in the July/August 2002 issue of Skeptical Inquirer. I think that many people are aware of pseudo-scientists; several illustrations are presented by Robert Park in his recent "Voodoo Science; the Road from Foolishness to Fraud" book. I would not be surprised to learn that pseudo-scientists exists in the cold fusion community. But I have no evidence that major contributors to that field are pseudo-scientists. Here is a quote from Kruglyakov's article:

"In Russia, even research institutes with pseudoscientific tendencies have appeared. I'll give only two examples: the International Institute of Space Anthropecology and the International Institute of Theoretical and Applied Physics. The first has even managed to attain state accreditation with the help of the Russian Ministry of Science. The second has received financial support both from the Ministry of Science and the Ministry of Defense for the well-known swindle of torsion fields. Peaceful coexistence between science and pseudoscience is impossible. From time to time, science attempts to unmask pseudoscience. The latter fights back with fierce hatred. Pseudoscientists are anxious to settle accounts with the Academy of Science, because the Academy is a great obstacle to these newly half-baked 'scientists'."

To what extent is the growth of pseudo-science facilitated by what happens in real science? To what extent is it influenced by what happens in education?

66) Cybernetics as Voodoo science

Ludwik Kowalski (May 26, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

An example of excommunication of the entire field of science (genetics) in the Soviet Union was mentioned in item 64. This reminded me of another example; cybernetics was also initially branded pseudo-science in the Soviet Union. To refresh my memory I went to the Internet and found some interesting quotations. According to

http://web.mit.edu/slava/homepage/disint.htm

"No other scientific or engineering discipline underwent such frequent and profound changes of attitude in the Soviet Union as cybernetics. In 1954, the Short Philosophical Dictionary defined cybernetics as a 'reactionary pseudo-science, an ideological weapon of imperialist reaction.' In the late 1950s, cybernetics was portrayed as an innocent victim of political oppression and 'rehabilitated,' along with political prisoners of the Stalinist regime. The Soviet lag in computing was blamed on the earlier rejection of cybernetics. In the 1960s, cybernetics was canonized in a new Party Program and hailed as a 'science of communism'."

And according to:

http://www.pact.sscc.ru/history/early.html

“Norbert Wiener’s book ‘Cybernetics or Control and Communication in the Animal and the Machine’ published in 1948 was actually banned in the USSR, because some ideas expressed by Wiener did not agree to the official Soviet doctrines. In 1953, the leading ideological journal ‘Problems of Philosophy’ published a notorious article ‘In whose service is Cybernetics?’ [3]. The author who hid himself under a pseudonym ‘Materialist’ wrote, in particular: ‘The theory of Cybernetics, trying to extend the principles of modern computing machines to a broad variety of natural and social phenomena without due regard for their qualitative peculiarities, is mechanicism turning into idealism. It is a sterile flower of the tree of knowledge resulting from a one-sided and exaggerated blowing of a particular trait of epistemology’. And further: ‘The imperialists are unable to resolve the contradictions splitting the capitalists’ world. They cannot prevent the approaching inexorable economical crisis. They try to find salvation not only in the frenzied arms drive but in the ideological weapon as well. In the depth of their despair they resort to the help of pseudo-sciences giving them some shadow of expectation to lengthen their survival.’

In the article ‘Cybernetics,’ in the 4th edition (1954) of ‘Concise Dictionary of Philosophy’ [4] this science was defined as a ‘reactionary pseudo-science which appeared in the USA after the World War II and became also wide spread in other capitalist countries; a kind of modern mechanicism’. One can easily imagine what it meant to defend and disseminate a ‘reactionary pseudo-science’ at those times in the Soviet Union!” Nevertheless, some scientists (described on the same web site) were brave enough to defend the field excommunicated by ideologically motivated officials. These scientists are now honored as pioneers of new technology. The two quoted references are:

3. "Voprosy Filisofii", 1953, No.5, pp.210-219.
4. “Kratkiy Filosofskiy Slovar”. Moscow, 1954, pp.236-237.

P.S.
Naturally, Stalin’s persecution of genetics was very different from the withdrawal of support for cold fusion in the US; nobody was imprisoned or killed here for promoting heretical ideas of cold fusion. But the phenomenon of pseudoscience is very real and society should be protected from those who exploit ignorance in order to benefit from

unscientific claims and manipulations. Making money on therapeutic magnets, for example, is a scam; the healing effects of such gadgets have not been validated, as far as I know. The same applies to devices delivering electric energy from a so-called “vacuum.” How can society be protected from con artists without confusing charlatans with honest scientists addressing non-conventional topics?

In my opinion **cold fusion researchers should be as active in exposing pseudoscience as those who do so under the banner of mainstream science.** How actively have they done this? How often do cold fusion researchers criticize each other? I suspect that this does not happen too often. I noticed, for example, that journals publishing cold fusion papers also publish papers devoted to topics of more questionable validity, such as perpetual motion devices, antigravity or hydrinos. Many cold fusion researchers probably disagree with such articles. But how often do they express this openly? I do not know.

67) Experiments in Texas

Ludwik Kowalski (May 28, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

What follows is another testimony about cold fusion experiments performed in Texas A&M University by Professor Bockris and his associates. Like Fleischmann, Bockris, (who retired in 1997) was a recognized expert in electrochemistry. He is the author of a 1993 textbook entitled "*Surface Electrochemistry: A Molecular Level Approach*." Was he lying about what has been observed? In my opinion, funds should have been made available to continue investigations of unexplained data. The quote below is an extract from his 2000 paper (*Accountability in Research,* 2000, vol. 8: p. 103). The entire paper, with references, can be downloaded from the library of the www.lent-canr.org web site.

"A quick start was made by my own group (in the Chemistry Department) partly due to my personal knowledge of Martin Fleischmann, who readily told me on the telephone some aspects of the technique he and his collaborators had used. The intense period of work at Texas A&M lasted about one year [ending in 1990]. Work in my own group continued until 1994. The following results from it have been published in refereed journals.

1. Multiple observations of the formation of tritium from deuterium; the tritium production turns on for several hours, then ceases. It can be started up again by means of an increase of the cathodic electrode potential. K. Wolf in the Cyclotron Institute also reported tritium in high concentrations in his own independent experiments. Later, he claimed that this must have been due to tritium present as an impurity in the palladium.

2. We observed significant amounts of excess heat in a few runs. The excess heat was observed in experiments of Appleby and Srinivasan in the TEES laboratories at Texas A&M.

3. In one run we observed heat and tritium together (we had not sought this relation in our other runs). The amount of tritium produced was about 0.1% of that necessary to explain the heat.

4. We found ^{4}He in the Pd lattice after prolonged electrolysis, the difficult analysis being done at North American Aircraft. The helium was about 100 times above background. (Melvin Miles subsequently found ^{4}He in the gas phase equal to around 1/4 that necessary to explain the heat.

5. We carried out about 20 experiments on the detonation of a mixture of solids. We found between 10 and 300 ppm of noble metals, in particular gold, in several experiments. However, the results were not reproducible.

6. In work on damage inside Pd electrodes we found that the impurities deposited on the electrode surface matched those in solution but that new nuclei (of species not present in the solution) developed inside the electrode after it had been saturated with deuterium or hydrogen. We also found Fe produced from spectroscopically pure carbon rods, arced under water of O_2 were present.

All these results have been subsequently verified in many independent labs (the detonation experiments by only two other labs)."

68) Two meanings of “impossible”

Ludwik Kowalski (May 30, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

In an essay devoted to the Second Law of thermodynamics, downloadable from http://philsci-archive.pitt.edu/archive/00000313/00/engtot.pdf, one finds a section dealing with the concept of “impossibility.” The author, J. Uffink, wrote: “. . . As we have seen, the basis of the second law is a claim that certain processes are impossible. But there are various senses in which one can understand the term

(i) ‘Possible’ may mean: ‘allowed by some given theory’. That is, the criterium for calling a process possible is whether one can specify a model of the theory in which it occurs. This is the sense which is favored by modern philosophers of science, and it also seems to be the most fruitful way of analyzing this notion. However, thermodynamics has a history of more than 150 years in which it did not always have the insights of modern philosophy of science at hand to guide it. So, one should be prepared to meet other construals of this term in the work of our main protagonists.

(ii) The term ‘possible’ may be taken to mean: ‘available in the actual world’ (or in ‘Nature’). This is the view that Planck and many other nineteenth century physicists adopted. For them, e.g. the statement that it is possible to build a system which exhibits a particular kind of perpetual motion means that we can actually build one. An important aspect of reading ‘possibility’ in this way is that the question of whether a process is possible or not, is not decided by the theory, but by ‘the furniture of the world’, i.e. the kinds of systems and interactions there actually are. This includes the systems and forms of interactions which we have not even discovered and for which we lack an appropriate theory. So, the claim that such a process is impossible, becomes a statement that transcends theoretical boundaries. It is not a claim to be judged by a theory, but a constraint on all physical theories, even those to be developed in the future. Clearly, the idea that the second law is such a claim helps
explaining why it inspired such feelings of awe..... ”

Those who say that cold fusion is impossible because experimental data have not been explained by an accepted theory should wait for the theory to be developed. Skeptics who think that cold fusion is not possible because it has never been observed in nature are probably not familiar with papers describing experimental data collected in the last ten years. I am referring to data on excess heat, and on unusual nuclear phenomena associated with it, as described in papers downloadable from the library at the www.lenr-canr.com web site. Some of them are summarized on my web site, for example, in items 55 and 60. Skeptics familiar with recent experimental data probably suspect that cold fusion claims are fraudulent. What evidence do they have to support accusations of fraud? The issue of poor reproducibility has already been addressed in the item 54 on my list. Here how it was described by B. Bush and J. Lagowski at *the Seventh International Conference on Cold Fusion* in 1998.

“Many laboratories have reported generating excess heat during deuterium oxide electrolysis at palladium cathodes, many of these reports being extremely convincing. The major difficulty with the topic of excess heat generation is not reproducibility, but rather control. The ability to control the circumstances of the electrolysis so that the excess heat can be ‘turned on, and turned up or down’ has eluded us as yet. Generally, generating excess heat remains unpredictable.”

69) International conspiracy?

Ludwik Kowalski (May 30, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

The item 68 ended with a quote from two electrochemists from Texas A&M, Bush and Lagowski. Their 1998 paper can be downloaded from the library at www.lenr-canr.org web site. Let me also quote from a paper of M. McKubre, F. Tanzella, P. Tripodi and P. Hagelstein. Their paper can also be downloaded from the above web site; its title is "The Emergence of a Coherent Explanation for Anomalies Observed in D/Pd and H/Pd System: Evidence for ^{4}He and ^{3}He Production." The paper was presented at the 8th International Conference on Cold Fusion (Italy, 2000); the first three authors are from Stanford Research Institute, the last is from MIT.

After describing the apparatus used, and after showing several convincing graphs, the authors concluded: "There exists a strong time correlation between the rates of heat and helium production measured using on-line high-resolution mass spectrometry. In experiments performed using three different metal sealed cells, three different calorimetric methods, by electrochemical and gas loading means and with ^{4}He analyses made at three different institutional laboratories, there is observed a quantitative or near-quantitative correlation between heat and ^{4}He production consistent with the reaction:

d + d - -> ^{4}He + 24 MeV *(lattice)*

Evidence for near-surface retention of ^{4}He in the lattice can be used to accommodate the discrepancy between measured and expected yields of ^{4}He. Evidence was obtained for excess heat production in the electrolysis of D_2O using "double structured" cathodes, supporting original claims by Arata and Zhang (6). Associated with this result, although not quantitatively correlated to it, is the production of a significant amount of ^{3}He within the cathode void volume, suggesting the presence of a second nuclear reaction. The origins of this ^{3}He and its theoretical implications are being explored."

Why are these authors accused of being voodoo scientists? Are they trying to deceive us by presenting fraudulent data? I do not think so. Their papers are not different from those published by mainstream scientists. The instruments they use are highly specialized and not available to typical teachers. That is why a panel of experts should be appointed to evaluate major cold fusion claims.

70) To petition AAPT?

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, NJ, 07055 (5/31/2003)

Cold fusion was mentioned in a message I received two days ago. The author of the extracted quote (see below) is a physics teacher; he often posts messages on our Internet discussion list, Phys-L.

> We have several list members who are genuinely and probably
> appropriately interested in issues considered by some as "fringe
> science"-- cold fusion comes immediately to my mind. I think we
> can and should entertain some of this inquiry, while recognizing
> that it isn't mainstream and likely is a blind alley. We all have room
> for growth by examining blind alleys. Certainly our students will
> encounter these fields and we need to know something of them
> as physics educators ourselves.

I think that this is a typical attitude toward cold fusion among physics teachers. The “room for growth” aspect is worth emphasizing; one can learn a lot via debates about variuous claims But let us face it, most of us are not equipped with sophisticated instruments, and with the expertise needed to use them properly. We know that only experimental data can show whether or not cold fusion claims are valid but we cannot collect such data in our laboratories. That is why a second official evaluation of cold fusion claims is needed at this time. To help students we must be helped by the scientific establishment.

The report from the first evaluation, initiated by the Department of Energy, and conducted by a panel of appointed experts, was released in November 1989, only nine months after the discovery of cold fusion was announced. It was based on what was known at that time. What should teachers think about new experimental data, such as accumulation of helium in cold fusion cells, or highly unusual isotopic ratios among heavier byproducts of cold fusion reactions? Several groups of researchers (from Japan, Russia, Italy and US) published articles about these phenomena. Are the authors of these publications incompetent? Are experimental data published by them fraudulent? Why are they often compared to voodoo scientists? Unable to answer such questions by ourselves we teachers expect to be guided by experts.

Many of us are familiar with convincing arguments that cold fusion could not possibly be dominated by the same nuclear reactions those occuring in hot plasma fusion. That conclusion, as far as I know, has been accepted by all scientists, including those from the cold fusion community. After criticizing the circumstances under which the discovery of excess heat was prematurely announced, and after emphasizing the need for controllable and reproducible data, the old report ended with the following: “However, there remain unresolved issues which may have interesting implications. [We are], therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system. “ I find the last sentence very significant; it indicates a desire to examine the outcome of better experiments, if they become available in the future. This was fourteen years ago; new experimental data are now available and they should be evaluated. (I already wrote about this in item 21 at html://blake.montclair.edu/~kowalskil/cf)

Would it be appropriate to formulate a petition asking the American Association of Physics Teachers (to which most of us belong) to initiate a second evaluation of cold fusion? Should I draft a petition and start circulating it on Phys-L? I have no experience with something like this. My note to The Physics Teacher, asking for a reevaluation of cold fusion,

was rejected. My letter to the editor of Physics Today, asking for the same thing, was ignored. Will my letter to the editor of The Physics Teacher, submitted several weeks ago, also be ignored? I do not know what else I can do. Who would suffer from another formal evaluation of cold fusion claims? Why is the scientific establishment unresponsive?

Here is what I wrote in a recent Phys-L thread: "We must accept data coming from real reproducible experiments, no matter how many theories they disagree with. But so-called 'gedanken experiments' are very different in that respect; we accept their conclusions only when these conclusions do not conflict with accepted theories." Cold fusion experiments are real, their results should not be rejected on the basis of desagreements with existing theories. Confirming that ^{4}He is produced in a hydrogen cell, for example, would be highly significant, even if the reproducibility were as low as 10%. The same would be true for highly unnatural isotopic ratios. If it were up to me I would focus on these two claims; they were made by several groups of recognized scientists and, if confirmed, would open new avenues of officially supported research. Lack of 100% reproducibility is always an indication that some important parameters are not yet under control and that additional work is needed.

To see what Schwinger (who shared Nobel Prize with Feynman) wrote on the subject of irreproducibility of cold fusion experiments see item 33 on my list. Very good descriptions of the current status of cold fusion, by three top scientists, can be found in item 24. If what you are reading now is printed on paper then you might not know that my cold fusion items are available over the Internet. The address is:

71) Josephson about voodoo science

Ludwik Kowalski
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ
(June 1,2003)

R. Park's "Voodoo Science" book has been referred to several times. A review of that book by Brian Josephson, a Nobel Laureate and a professor of physics at the University of Cambridge, can be seen at:

http://www.tcm.phy.cam.ac.uk/~bdj10/articles/park.html

Josephson wrote: "We find in Park's book the official story regarding a number of "mistaken beliefs". What one will not find -- and is hard to find anywhere if one does not know where to look to bypass censorship -- is the additional information that might lead one to conclude that the official view does not tell the whole story. Regarding the paranormal, Park follows others in quoting a lecture on "pathological science", given by noted chemist Irving Langmuir, concerned with claimed phenomena that are difficult to reproduce. In a number of cases this was because the observed effects were clearly shown to be caused by a flaw and went away when a properly designed experiment was done. But Langmuir then went on to make the dangerous generalisation that if any effect is weak or difficult to reproduce then the effect is not a real one. This does not logically follow; an effect may be weak or difficult to reproduce simply because it is weak or difficult to reproduce. It is not easy, for example, to detect neutrinos from the Sun, and different laboratories tend to get different results in this research. . . .

It is interesting to look both at Park's account of the history of cold fusion and at that of the protagonists, presented in a video documentary *Cold Fusion: fire from water* (available from www.infinite-energy.com). Park impresses on the reader the fact that if the process that generates the heat is really fusion then one would expect to see fusion products. He fails to mention here, as the video does, that the small amount of such products anticipated, given the amount of energy generated, was eventually observed, and in just the right quantity. All mention of positive results, such as the experiment where, by what appears to be a sound method, it was found that the energy generated was considerably in excess of anything that could be explained conventionally, is collapsed into a paragraph where Park notes that many claims are soon withdrawn because of errors being found (as also happens in ordinary science).

This device legitimises the dismissal of all positive results, and so also the corollary 'cold fusion is no closer to being proven than it was the day when it was announced'. This is a seriously misleading statement. There *are* scientific arguments against cold fusion, but equally there were arguments against continental drift. ..... Despite its faults, *Voodoo Science* is an interesting book, with many stories about the kinds of mistakes made by people who believe they have made an important discovery. But it should carry a disclaimer that is the converse of the one with which Park ends his 'What's New' column on the American Institute of Physics website: 'the opinions in this book are unquestioningly shared by many scientists, but they should not be'."

72) Anecdotal Evidence ?

Ludwik Kowalski (June 27, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

The fragments below were extracted from the Introduction to Tadahiko Muzino's book "Nuclear Transmutation: The Reality of Cold Fusion." The book, published in 2000, can be ordered from Amazon.com. The introduction was written by Jed Rothwell; it can be downloaded as "MizunoTnucleartra.pdf" file from the library at html://www.lenr-canr.org

* * *

. . . Mizuno wrote this short book about his work and personal experiences. It is the best informal account yet written about the daily life of a cold fusion researcher. It gives you a sense of what the job feels like. It is not intended to be technical. For technical details, the reader is invited to examine Mizuno's numerous scientific papers, some of which are listed in the references. One event described here which is not described in the technical literature is an extraordinary 10-day long heat-after-death incident that occurred in 1991. News of this appeared in the popular press, but a formal description was never published in a scientific paper.

Mizuno says this is because he does not have carefully established calorimetric data to prove the event occurred, but I think he does not need it. The cell went out of control. Mizuno cooled it over 10 days by placing it in a large bucket of water. During this period, more than 37 liters of water evaporated from the bucket, which means the cell produced more than 84 megajoules of energy during this period alone, and 114 megajoules during the entire experiment. The only active material in the cell was 100 grams of palladium. It produced 27 times more energy than an equivalent mass of the best chemical fuel, gasoline, can produce. I think the 36 liters of evaporated water constitute better scientific evidence than the most carefully calibrated high precision instrument could produce. This is first-principle proof of heat. A bucket left by itself for 10 days in a university laboratory will not lose any measurable level of water to evaporation. . . .

It is a terrible shame that Mizuno did not call in a dozen other scientists to see and feel the hot cell. I would have set up a 24-hour vigil with graduate students and video cameras to observe the cell and measure the evaporated water carefully. This is one of history's heartbreaking lost opportunities. News of this event, properly documented and attested to by many people, might have convinced thousands of scientists worldwide that cold fusion is real. This might have been one of the most effective scientific demonstrations in history. Unfortunately, it occurred during an extended national holiday, and Mizuno decided to disconnect the cell from the recording equipment and hide it in his laboratory. He placed it behind a steel sheet because he was afraid it might explode. He told me he was not anxious to have the cell certified by many other people because he thought that he would soon replicate the effect in another experiment. Alas, in the seven years since, neither he nor any other scientist has ever seen such dramatic, inarguable proof of massive excess energy.
Here is a chronology of the heat-after-death event:

March 1991. A new experiment with the closed cell begins.
April 1991. Cell shows small but significant excess heat.
April 22, 1991. Electrolysis stopped.
April 25. Mizuno and Akimoto note that temperature is elevated. It has produced 1.2 H 107 joules since April 22, in heat-after-death. F. Nakano, "Mohaya hitei dekinai jyouon kakuyuugou [The reality of cold fusion can no longer be

denied],” Bungei Shunju, September 1991
The cell is removed from the underground lab and transferred to Mizuno’s lab. Cell temperature is >100 deg C.
April 26. Cell temperature has not declined. Cell transferred to a 15-liter bucket, where it is partially submerged in water.
April 27. Most of the water in the bucket, ~10 liters, has evaporated.
The cell is transferred to a larger, 20 liter bucket. It is fully submerged in 15 liters of water.
April 30. Most of the water has evaporated; ~10 liters.
More water is added to the bucket, bringing the total to 15 liters again.
May 1. 5 liters of water are added to the bucket.
May 2. 5 more liters are added to the bucket.
May 7. The cell is finally cool. 7.5 liters of water remain in the bucket.
Total evaporation equals:
April 27 10 liters evaporated. Water level set at 15 liters in a new bucket.
April 30 10 liters evaporated. Water replenished to 15 liters
May 1 5 liters replenished.
May 2 5 liters replenished
May 7 7.5 liters remaining.

Thus, evaporation since April 30 is: 15+5+5-7.5=17.5 liters. Total evaporation is 37.5 liters. The heat of vaporization of water is 540 calories per gram (2,268 joules per gram), so vaporization alone accounts for 85 megajoules. One aspect of the heat-after-death event seems particularly strange. It is as if the cathode is trying to maintain stasis inside the cell. After the external 60 watt heater was turned off, the heat-after-death reaction increased just about enough to compensate for the loss of external heat. This sounds like an instrument error. It prompted Mizuno to double check all instrument readings with meters attached directly to the sensors. As unbelievable as this sounds, it is a real phenomenon which others have observed. Stanley Pons noted that the cold fusion effect has a kind of “memory.” After a perturbation, temperature tends to return to a fixed level. Perhaps this is not so strange. The physical configuration of deuterons in the metal controls the power level.

. . . Mizuno has often talked about the prehistory of cold fusion. Most great discoveries are visited and revisited many times before someone stakes a permanent claim. People sometimes stumble over a new discovery without even realizing what they see. Mizuno did his graduate and post graduate work on corrosion using highly loaded metal hydrides. His experiments were almost exactly like those of cold fusion, but they were performed for a different purpose. In retrospect, he realized that he saw anomalous events that may have been cold fusion. At the time he could not determine the cause, he did not imagine it might be fusion, and he had to leave the mystery unsolved. No scientist has time to track down every anomaly.

. . . Recently, Mizuno, Bockris and others have increasingly focused on so-called “host metal transmutations,” that is, nuclear reactions of the cathode metal itself. The cathode metal was inexplicably neglected for many years. The term “host metal” is misleading. It was an unfortunate choice of words. It implies that the metal acts as a passive structure, holding the hydrogen in place, cramming the deuterons or protons together. The metal is a host, not a participant. The hydrogen does the work. Now, it appears the metal itself is as active as the hydrogen. The metal apparently fissions and fusions in complex reactions. Now the task is to think about the metal, and not just the hydrogen. Theory must explain how palladium can turn part of itself into copper and other elements with peculiar isotopes. One of the few “Eureka!” events in this book is the moment when Mizuno and Ohmori saw the scanning electron microscope images of the beautiful lily-shaped eruptions on the surface of Ohmori’s gold cathodes. This was visual proof that a violent reaction takes place under the surface of the metal, vaporizing the metal and spewing it out. Later, these vaporized spots were found to be the locus of transmutation. Around them are gathered elements with an isotopic distribution that does not exist in nature. The only likely explanation is that these isotopes are the product of a nuclear transmutation.

* * *

What might skeptics say about recent cold fusion data?

1) Muzino and others in Japan are liars, like Karabut and others in Russia, like Bressani and others in Italy, like Lonchampt and others in France, like Bockris and others in the US. The data are fraudulent.

2) These people only pretend to be scientists. Their Ph.D.diplomas were counterfeit; their professorships at famous universities were bought; the books and hundreds of articles they published were produced by somebody else. They are members of an international "mutual support society."

3) We already know everything about nuclear phenomena; facts which disagree with existing theories are not acceptable. Absence of commensurate amounts of neutrons and protons is a sufficient reason to ignore claims about unusual nuclear processes.

4) Cold fusion researchers were often wrong in 1989. Therefore what they are finding now must also be wrong. They should never be forgiven for announcing a discovery via a press release, or for claiming that excess heat experiments are very simple.

5) Claims made under the banner of cold fusion were not described in articles published in leading journals. Therefore they cannot be accepted. The editors of these journals refuse to publish cold fusion articles; they know better what is right and what is wrong.

6) Neither the Department of Energy nor the National Science Fundation support research in the area of cold fusion. Therefore such research is not worth taking seriously. Those who perform experiments cannot be objective about their own research.

7) Practical applications of cold fusion have not been demonstrated; therefore the underlying phenomena cannot be real.

8) We know nothing about recent cold fusion findings; therefore they must not be correct. The entire field was declared pseudoscientific in 1989 by a panel of experts. The opinion of experts must be respected; it can not be challenged by new findings.

9) Experiments should be 100% reproducible before they can be accepted.

I agree with the last reservation. Lack of reproducibility is a clear indication that some important parameters are still not under control by experimentallists, and that conclusions are tentative. I elaborated on this in item # 54. Electrostatic experiments used to be called "irreproducible" before the effect of humidity was recognized. I do not think that it is appropriate to identify "irreproducibility" with "not being real;" Irreproducibility is typical in all areas of emerging science. I see nothing unusual when a competent cold fusion scientist is successful only eight or nine times out of ten to demonstrate a new phenomenon. As far as i know, this is typical in only some types of cold fusion experiments. The situation is no longer as bad as it was in 1989.

That is why I think that the time is right for a new investigation of the entire cold fusion field by a panel of experts. They should focus on experiments which are nearly always
reproducible, not on observations which were reported only once or twice. If you, a reader of this item, do not accept my suggestion, then please explain your position on the Phys-L list. Perhaps your message will influence our thinking. Or write to me at : <kowalskil@mail.montclair.edu>, if you prefer. Thanks in advance.

73) Reproducible Excess Heat

Ludwik Kowalski (June 29, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

What a coincidence. Yesterday I posted an item about Mizuno's work in Japan. Today I found a very recent French report confirming Mizuno's results. I have no idea who the author (Jean-Louis Naudin from JLN-Labs) is. I will assume that he is a student because in one place he writes: "I am very grateful to Professor Pierre Clauzon for his contribution to the CFR project and his help during some CFR tests runs and also to Professor Jean-François Fauvarque and Gérard Lallevé from the " Laboratoire d'Electrochimie Industrielle" of the CNAM (Conservatoire National des Arts et Métiers) from Paris, for their scientific support and their contribution to this project." At his website at:

http://jlnlabs.online.fr/cfr/html/cfrdatas.htm

Jean-Louis summarizes results of 33 runs of excess heat experiments completed only four days ago (on June 25, 2003). He writes: "Today, I can say that the Mizuno-Ohomori's Cold Fusion Reactor is fully replaceable and that it works very well as described in their papers. You will find below the latest measurements results that I have performed since May 7th, 2003"

I was not able to follow details but conclusions are very impressive. In run 28, for example, when 170 grams of water were evaporated, the electric energy was supplied to the setup at the rate of 1200W while heat was generated at the rate of 3093 W. The blue line in the last figure, showing what would happen if there were no excess heat, is significantly different from the red line representing the results of real calorimetric measurements. See http://jlnlabs.imars.com/cfr/html/cfrpd.htm for additional details.

In my opinion the results are reasonably reproducible, as far as reported data from 33 runs are concerned. But will they be reproduced by other researchers? The blank run seems to indicate the absence of a systematic error. This reminded me Karabut's data (item 13 on my list). Naturally, skeptical accusations raised about Mizuno data (see item 72 on my list) can also be raised about Naudin's data.

P.S.
After posting the above I sent an email message to Jean-Louis. The reply was: "Thanks for putting a link to my Cold Fusion replication experiment... For your information, I am not a student as you have supposed (I am 45 years old...), I work in my own and private lab and some French physicists work closely with me in this field of research..."

74) Reproducible Excess Heat, part 2.

Ludwik Kowalski (June 30, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Here is how the experiment of Mizuno, replicated by Naudin (see item #73 on this list), was described by Mallowe. Dr. Eugene F. Mallove is the Editor-in-Chief of the "Infinite Energy Magazine Cold Fusion Technology." He is also the author of "Fire from Ice," a book about cold fusion published by John Wiley & Sons, Inc. (in 1991). I am surprised that hydrinos are mentioned at the end Mallowe's description of topics to be investigated. Linking hydrinos with cold fusion is not desirable, I think. My item #57 is about hydrinos. I would like to hear arguments showing that excess heat can not possibly result from chemical reaction taking place in experiments quoted by Mallowe. I like situations in which different teams work on similar experiments. The experiments which I was invited to participate in Salt Lake City was similar but it was focused on transmutations rather than on excess heat. No evidence of transmutations was found.

****
A word of WARNING right up front: This is potentially VERY DANGEROUS work and must not be done without maximum, safety precautions and supervision by those thoroughly versed in laboratory safety! It involves high-temperatures, high-voltages, explosive mi xtures of oxygen and hydrogen, caustic solutions, and steam generation that if improperly contained could cause a deadly explosion. These are just the beginning hazards. This is unknown territory. Drs. Ohmori and Mizuno measured the transmutation of elem ents in this experiment. Thus, until further notice, and despite your possible skepticism about their claim of transmutation, this work must be considered, by definition, nuclear experimentation. With that said, we encourage every thoughtful group who can do this experiment safely to attempt it. Infinite Energy and Cold Fusion Technology, Inc. take no responsibility for the known or unknown radiation or other hazards that are associated this experiment.
****

Dear Colleagues:

After much work we now have what appears to be a marvelous do-it-yourself "cold fusion" experiment. Any reasonably equipped chem/physics lab can see the effect within days to a week -- if they get their act together. The experiment has the following qualities:

1. It is visually and audibly spectacular -- brilliant glowing, pink, purple, lavender with white flashes on an underwater tungsten (W) electrode (e.g. 2 mm x 5 mm W foil or 1 cm x 1.6 mm diameter tungsten welding rod). A plasma-like underwater discharge on the electrode that often manages to disintegrate or melt tungsten underwater with only about 50 to 80 watts of power over a short period. (Tungsten's melting point is 3680 K or thereabouts.) The sound of the underwater "explosions" on the cathode -- brilliant white flashes on the purple background plasma -- is very impressive.

2. It is *totally reproducible* -- at will -- with no loading time as in the Pd/heavy water experiments

3. Calorimetry is simple to do because there is so much steam energy evolved from the reaction that by simply tallying the amount of water vaporized as steam, one gets over-unity every time (so far). Three groups have already gotten *preliminary* over-unity results: 1. Ohmori and Mizuno in Japan, who introduced the phenomenon at ICCF-7 (O/U estimated at 2.6/1); 2. Gene Mallove and FAA engineer Ed Wall here in Bow, NH during the past ten days -- work continuing -- (CONSERVATIVELY 1.4/1); 3. Engineer Mark Hugo of Northern States Power in Minnesota (but his affiliation has nothing to do with his home experiment) -- (CONSERVATIVELY 1.5/1), but owrk still continuing to check for errors. Chemist John Thompson in the Bahamas, who attended ICCF-7, was the first person outside of Japan to reproduce the effect and will do calorimetry on it soon. This will be in IE #20 out on July 22.

4. No one has patents or may be able to get them since the effect was noticed in other forms (1916!) and reported extensively in the Journal of the Electrochemical Society, April, 1950, p.133 in an article titled "The Anode Effect in Aqueous Electrolysis," by Herbert Kellogg of the School of Mines, Columbia University. New York -- Hal Fox found this marvelous article, since it relates to some of the work his Trenergy Company is doing weith charge clustgers and radioactivity reduction. This may, indeed, be related to the underwater electrolysis ability to remediate nuclear waste. But -- OF COURSE! -- NO *calorimetry* was done in 1950. No one had any idea that such simple systems could be O/U. The systems were studied for other reasons. Further: the present tungsten effect is seen mainly on the cathode, but it can make the Pt anode incandescent too at lower water temperature (say 50 C) -- we normally work over 80 C. It is very mysterious -- was so to Kellogg in 1950 and remains so.

5. Ohmori and Mizuno found major evidence for transmutation of elements and volcanic ejection of metals from the tungsten surface -- these SEM photos were reproduced in their article. They find Hg, Os, Kr, Zn, Cu, Ni, Fe, Cr, Si, and Mg -- with anomalous isotopic content. Just as I said, in IE #15/16, this subject is more properly called ©¯Electro-Alchemy"

6. WARNING: Ohomori and Mizuno experienced significant apparent electromagnetic effects on their instruments. They were unsure whether some of the effect on their neutron counter were evidence of neutrons -- I doubt the latter, as did Srinivasan of BARC at ICCF7. I have kept a Geiger counter on during our experiments -- absolutely no sign of major ionizing radiation, but of course it could be localized within the cell.

Ohmori and Mizuno's paper at ICCF7: " Strong Excess Energy Evolution, New Element Production, and Electromagnetic Wave And/Or Neutron Emission in the Light Water Electrolysis with a Tungsten Cathode." T. Ohmori and T. Mizuno, Catalysis Research Center, H okkaido University

Here is my recommended recipe for an experiment to demonstrate the effect:

1. Take a 250 ml glass beaker, fill to about 200 ml level with 0.5 molar (0.5 M) K_2CO_3 -- potassium carbonate solution

2. Get 0.5 mm diameter Pt wire for both anode and cathode leads -- about 15 cm for each lead is adequate length. Shield them with teflon tubing down to the connection point with the Pt or W.

3. Use a small piece of Pt foil -- about 2 mm x 5mm on the anode (positive lead) crimped mechanically to the Pt wire -- no welding is needed.

4. Use a 2 mm x 5 mm size W foil on the cathode - negative side. It is tricky to attach the W foil (we used 0.1 mm thickness, which can be pierced with difficulty and the Pt lead wired through). Or, if W welding rod 1/16-inch diameter is available, wrap the Pt wire around the W piece about 0.5 to 1 cm long. Warning: The reaction is so violent that it is hard to get the cathode piece in rod form not to fall out of its Pt wire cage! Runs up to 10 minutes or so are usually OK. Mark Hugo has run for up to 75 minutes, condunsing steam from the reaction -- but he has put other ingredients into the brew such as Li, and he has used a thicker cathode of 1/8-inch W rod.

5. Get a DC power supply up to 5 amps capacity and up to 200 volts. (I am eager to try beyond 180 volts, but we may need a concrete bunker before we try that! Eager also to try heavy water!) You can use a variac AC source to make DC power-- use a bridge rectifier and capacitor to make DC from the AC output. Install voltage and current metering devices -- digital display preferred, data acquisition system if you want to get fancy on the calorimetry later. I'm sure Scott Little and Mitch Swartz could do this soon if they put their equipment into this specialized service. This is an excellent experiment for Barry Merriman too!

6. Heat up the beaker solution to 80 C either by electrolysis at low DC input power -- e.g. 20 V, 1.8 to 2 amps -- or with an external hot plate. (Turn off the hot plate and **remove it** if calorimetry is being used.) At about 80 deg -- sometimes at a lower temperature -- crank up the volts to 120 to 180. The effect changes appearance as voltage increases. Current will drop substantially to 0.2 to 0.4 amps as the sheath of steam surrounds the glowiing plasma-

sheathed cathode. Keep an alcohol thermometer suspended in the solution to measure the temperature. I would *initially* avoid thermocouples because of the threat of violent electromagnetic interference in this unknown phenomena.

In calorimetric assessment: Heating credit should be taken for the full mass of water in the cell from the initial temperature of say 80 C to the boiling point. However, you may find it difficult to push the average solution temperature up to 100C (we were only in the low to mid 90s), because the steam ejected cools the solution so rapidly. The boiling point is elevated -- McKubre estimated to me in aprivate communciation by only 0.25 deg C for such a solution). This is wonderful, because we WANT steam. It will be no problem at all to power steam engines with this, if pending thorough verification of excess energy (This *is* work in progress that must be confirmed!) we figure out how to get the power ratio high enough, if it is not there already. The main source of the excess is the amount boiled off: water vaporized requires about 2260 J/gm.

Why was this missed by other cold fusion people? Simple: everyone was looking for a sedate reaction that P&F had started with when the real pay off was in these higher voltage systems that trigger with metals like tungsten. W is recommended due to its temperature resistance, but John Thompson has found that other metals such as Al, Cu, Ni, and Zr also work -- as far as the *visible* effect. The colors of the emissions are different -- different hot plasma near the cathode surface.

Other parameters that need to be explored:

* Higher voltage

* Can energy be extracted from the recycled water after steam condensation or if Mills-type hydrinos are formed, do they become "inert"?

* Other electrolytes -- KCl also works, according to Thompson, try higher molarity values

* Other metals

* Pressurized systems -- BE CAREFUL!!!

* Recombine oxygen and hydrogen -- but a very small part of the effect, undoubtedly -- to get extra energy in the output

* Try heavy water in various mixtures with light water

* Detect electromagnetic pulse from the device -- if it is there as they found in Japan

* Examine the element production and non-natural isotope ratios formed

* Scanning Electron Microscopy imaging for morphology of craters

* Look for radiation -- use film fogging techniques, CR-39 plastic detectors, etc.

This will keep a lot of people busy for a long time. As soon as we pin down the thermal characteristics a bit more, we and others well be hell-bent to scale up to larger power-producing units -- with SAFETY FIRST as our motto.

****

This is a typical, very brief O/U investigation run that Ed Wall and I performed here recently in an uninsulated glass beaker on a metal surface -- VERY rough calculation, conservative, we think. Among other factors reducing effect apart from ZERO insulation is the recondensation and re-boiling of material -- we had a plastic cover on the beaker with holes drilled in it. A distillation recondensation device would be preferred to observe water evolved as steam.

Input: 0.7 to 0.8 amps, average 0.75 A input at 168 volts => 26,590 J

Duration: 3 minutes, 31 seconds

Solution reduced from 183 ml to 173 ml due to boil-off

Output = 10 x 2260 J/gm H_2O + 183 x (about 15 C rise during heating to full boiling at about 92 C) x 4.18 J/gm C = 34,060

output/input = 1.28

Credit for uninsulated vessel and re-bailing of condnsed liquid could easily push this to 1.40 and beyond. Much more work needs to be done.

I hope that other Vortexians will try this -- CAREFULLY, please!

****

Ohmori and Mizuno did calorimatry on the last few mintues BEFORE boiling and compared the rate of temperature rise to that of a joule heater's effect on the same volume of electrolyte. That's how they got their 2.6/1. See Infinite Energy #20 for more information in late July.

75) Do not mix science with fiction

Ludwik Kowalski (July 5, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

One thing that often discredits the cold fusion field is the premature rush toward speculations about its technological applications. Those who promote such speculations are supplying skeptics with arguments used against cold fusion. I know that some technological inventions were made long before the underlying science was understood. But in the area of cold fusion, at this stage, the emphasis should be on basic science, not on science fiction and on unverified commercial claims. I saw many very good articles in "Infinite Energy Magazine" of Eugene Mallowe, and in "Journal of New Energy" of Hal Fox, but some articles appear to be junk. The cold fusion field is controversial enough; what is the purpose of mixing its topics with even more controversial topics, such as Edison engine, Mills' engine, hydrinos, or antigravity?

To illustrate premature technological speculations let me show extracts from the "Cold Fusion Goes Commercial" editorial. The entire piece (from the Infinite Energy Magazine, vol. 1, No 2. 1995) can be seen at the following Internet web site:

http://www.planetarymysteries.com/energy/ie.html

"As it stands now, 'cold fusion' and allied 'new energy' technologies, in which energy appears to materialize perhaps literally from the vacuum quantum fluctuations of space or from subtle mass conversion to energy - are possibly the greatest commercial opportunities of this century..... Now for an incredible commercial bombshell -a water-fuel device that did not originate from the mainline cold fusion field at all, but which is very definitely penetrating the marketplace already in eastern Europe. We have learned that in a former region of the Soviet Union, now the country of Moldova (known also as Moldavia), the VIZOR Corporation in Kishinev has already sold thousands of heating units to homes and industries!..... But what is most important is that hundreds upon hundreds of satisfied customers have ratified the technology in the marketplace!..... "

Here is how this device was described, after being tested by a US research team from Texas. "A water-heating device developed in Kishinev, Moldavia by Dr. Yu. S. Potapov has been reported to produce a heat output up to 3 times greater than the energy required to drive it. A Russian physicist, Lev G. Sapogin, has offered a theory to explain this phenomena in his paper entitled, 'On One of Energy Generation Mechanism in Unitary Quantum Theory'. We obtained a Potapov device and conducted a series of energy balance measurements on it. No evidence of over-unity performance was observed." The entire test report is available at the following Internet web site:

http://www.earthtech.org/experiments/yusmar/potapov.txt

A TV show can also be used to promote science fiction. Here is an illustration; it is one part of a transcript of the ABC's program "Good Morning America," shown on June 11, 1997.

"**MG** (voice over): During the last year, Patterson's little beads have led to a huge surprise. Not only do they produce heat. It turns out, they also neutralize radioactivity.

JP: (Patterson) This is the cell system down here . . .

MG It sounds like such an amazing development, the company is attracting big name scientists, like Norm Olsen. He

traveled all the way from Hanford, Washington, where the government stores billions of gallons of high level radioactive waste.

NO (Olsen): If this technology works out as advertised, it means we could significantly reduce the radioactivity of nuclear waste in the United States, and the world.

MG: But does it work as advertised? We decided to put it to the test.

JP: What I have in this cup is radioactive uranium in a water medium.

MG: And that's what's sending that Geiger going crazy, right?

JP: Yes.

MG: So the idea is that the radioactive material will then flow through your device, and actually remove the radioactivity?

JP: Yes.

MG: I don't believe it. Go ahead and push the button. Let's see if it works. (Laughs.)

MG: The experiment began at high noon, with the Geiger counter registering well over 300. But by speeding up the video, you can see that after a couple of hours, the radioactivity was cut down by more than half -- a reduction that would take billions of years to happen naturally.

NO: I am really encouraged by what I have just seen. Our plan now would be to take it back to Hanford Labs, test it out under controlled circumstances, and fully prove it. And go as far as we can go with it. ....."

If I were in Norm Olsen's position I would ask some questions. Is it not possible that the distribution of radioactivity withing the cell changes during the electrolysis thus reducing the count rate? Is it possible that the reduction of radioactivity is due to the fact that some of it is escaping from the cell? I would not take the cell to Hanford Labs before answering such questions for the existing setup. As far as I know, even now, six years later, no accepted evidence exists that radiactivity can be reduces by a process taking place in an electrolytic cell.

For more about this see; http://www.altenergy.org/3/new_energy/cold_fusion/workers/workers.html

76) Secrecy in cold fusion research

Ludwik Kowalski (July 6, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Secrecy in science and technology is a big issue; I am not trying to address it in general. But that issue was brought to my attention several times while I was reading cold fusion materials, especially the writing of two scientists: George Miley (see item 36) and Benjamin Bush. In a section entitled "Scientific Integrity and Openness." Miley wrote: "Integrity in science has been a 'hot issue' throughout the saga of CF. This issue has sometimes been confused with the problem of 'openness' of discussion. [Integrity] has been seriously hampered by the dominance of various companies and entrepreneurs in CF who hope to gain advantage through patents and proprietary information. Integrity and openness are, in fact, entirely different issues. Integrity must be maintained at all costs; openness is highly desirable, but is not always possible. In order to succeed, companies must often protect their base intellectual property. . ."

He also wrote: " 'Stopping wasteful funding on CF' [became an official policy in the US]. Thus, small companies and individuals end up, by default being the main funding source for CF. As a result, they in turn, rightly feel that their investment is entitled to protection via patents and secrecy. Normally, in other fields, government funded research provides a balance of funding that leads to a flow of open publications covering the basic science underlying the field, while the practical technology funded by companies remains proprietary. In CF, 'open' science only comes from a very few academics or others who can undertake research without 'strings' attached. A majority of the work is more guarded."

B. Bush, interviewed about his research (Infinite Energy Magazine, January-February, 1997, page 32) was not willing to provide a clear answer because , "at this juncture, [the answer] does involve proprietary aspects." Then he elaborated by saying that "there is no question that 'secrecy' tends to hurt the general development and dissemination of science. On the other hand, funding is necessary for equipment, lab supplies, release time from teaching, etc. In an atmosphere where the government is providing no funding, as in the case of CF research, private funding becomes extremely important. Private investors want a return on their money, and patents containing proprietary materials are essential. Thus, in the present atmosphere of no government funding,'proprietary aspect' becomes a 'necessary evil' relative to the development of the Science." At one time I contacted a cold fusion researcher and asked him to write an item about cold fusion patents for this list. He declined on the basis of the "proprietary aspect" of the issue. His pending patents could possibly be threatened, he wrote, by a description of what is going on in the US Patent Bureau. I was surprised.

77) More evidence of nuclear reactions

Ludwik Kowalski (July 7, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Motivation for this item was provided by the 2000 paper of G. Miley et al. entitled "On the Reaction Products and Heat Correlation for LENRs." The rest of this paragraph is the abstract of their paper. " 'Low Energy Nuclear Reactions', or LENRs, typically involve electrolytes containing light water along with electrodes made of metals such as Ni, Ti and Pd. In these experiments a variety of reaction products (isotopes), with masses both higher and lower than that of the host electrode material, have been observed at the University of Illinois (U of IL). Related results, often termed "transmutation" studies, have been reported by other researchers. These observations suggest that proton-metal initiated reactions occur in such LENR cells. This paper discusses evidence that the production of these reaction products is correlated with the excess heat also frequently observed in LENR cells. Such a correlation for LENR reactions would be equivalent, in principle, to the correlation of He-4 with excess heat that is reported for heavy water-Pd experiments where a D-D reaction is postulated."

The entire paper, a presentation at the 8th International Cold Fusion Conference, can be downloaded from the < http://www.lenr-canr.org > web site; the name of the file is <MilesMradiationm.pdf>. George Miley is a prominent American experimental scientist in the area of cold fusion. (He also wrote on social aspects of scientific research, as illustrated in item #36 at my cold fusion web site.) The paper begins by reminding us about experiments in which accumulation of ^{4}He, presumably resulting from D+D encouters, was observed in experiments with palladium cathodes in heavy water cells. Then the paper displays a figure listing reaction products identified in Miley's cathodes. I was impressed by the number of displayed products, and by the fact that their atomic masses cover a wide range (from lless than 10 to more than 210). The average reaction rate, in terms of [atoms/(cc*sec)], is specified for each product. The authors focus on high yield products (production rates exceeding 10^{13}) because their presence can not possibly be attributed to contamination. Most of the products are not radioactive. Isotopic ratios are often significantly different from those found in nature.

Such products have been reported by many research teams and their presence is a strong indication that something highly unusual is going on. This has already been discussed in earlier publications. Miley and his team go beyond this point; they focus interpretations. The hypothesis is that nuclear reactions are somehow induced when protons (nuclei of hydrogen) interact with the cathode material. Knowing the amount of excess heat generated, and the number of atoms produced, authors are able to calculate the average energy released. The result, 0.15 MeV per reaction, is by many orders of magnitude higher than energies released in most exothermic chemical reactions. But it is about 25 smaller than in common hot fusion reactions. Note that the reported reaction rates were calculated by dividing measured numbers of atoms by the time of operation. The numbers would be much larger if atoms where produced in short bursts (rather than continousely).

I am not a chemist and I take it for granted that the excess heat measured can not possibly be due to chemical reactions. I know, however, that only a nuclear reaction can transform one chemical element into another. The authors report that "a striking pattern [in the mass distribution] consistently observed in these measurements is that the high-yield reaction products occur in four mass ranges, roughly A = 20-30, 50-80, 110-130, and 190-210 [4]. Statistically significant shifts in isotope ratios from natural abundance are also observed for many of the products [2, 3]. Numerous precautions were taken to guard against impurities in these measurements (see references 2, 3). This includes use of special "clean" systems, blank runs, and precision diagnostics prior to and following runs.

Other evidence of the nuclear basis for these results included the observation of low energy X-ray and/or beta emission from electrodes after a run and statistically significant shifts in isotope ratios for key elements. The general trends from these results are reasonably consistent with reaction product measurements by other workers (see the discussion and references in references 4, 5). However, others have often termed their work “transmutation studies” as opposed to “reaction product studies”. For that reason, other studies have not generally focused on the total product yields or on correlations with heat.” Note that abnormal isotopic compositions could not result for contamination.

Is Professor Miley incompetent? Is he a liar? Why is his report, and similar reports of other researchers, are not taken seriously by leaders of our scientific establishment? Why are all cold fusion investigators accused of practicing pseudo science? How does Miley’s cold fusion report differ from reports presented by the so-called “true scientists?” The situation is not good. I tried to do something about this but Physics Today, rejected my “letter to the editor.” My hope was that the letter would trigger a discussion about the way to restaure normality. Why should cold fusion be treated differently than other areas of science?

78) An older fight for acceptance

Ludwik Kowalski (July 12, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

It is well known that neither pure water nor table salt are good electrical conductors. But the resistance of a solution of salt in water is relatively low. How can it be? This was a dilemma puzzling 19th century scientists. It was brilliantly solved by Svante Arrhenius, a Swedish scientist (1859-1927). According to C.G. Beaudette, the grand daughter of this scientist was a researcher at Utah University when cold fusion discovery was announced in 1989. After the press conference she spoke with Fleischmann and Pons. She said “Well, when my grandfather proposed electrolytic dissociation, he was dismissed from the University. At least that won’t happen to you.” She was mistaken, both scientists were dismissed.

The history of Arrhenius’s model of molecular dissociation is being presented by Beaudette as an example of difficulties encountered by those who promote new ideas. Let me quote from the Chapter 11 of his interesting book: “Excess Heat: Why Cold Fusion Research Prevailed,” Oak Grow Press, LLC, South Bristol, Maine, USA, 2000. I strongly recommend this book for a school library. Arrhenius’s “story bridged the turn of the twentieth century. His breach with the orthodox scientific community of twenty years duration, his intellectual survival in a small group with his scientific fellows, and the argument whether his discovery was one of chemistry or physics, all parallel the instance of the Fleischmann and Pons controversy.

Arrhenius finally achieved collegiality between himself and the scientific world by persistently teaching his discoveries. His story is almost prophetic of what happened in "cold fusion" research during its first ten years. He was banished from both his university and the Swedish scientific establishment. He overcame that affliction and went on to great acclaim as a revered elder statesman within the European scientific community. He accomplished much of this by attaching himself to a foreign scientist of recognized integrity.

Arrhenius's principal scientific discovery asserted that when a salt is dissolved in water, each molecule of the salt separates into electrically charged electrolyte particles that had been named ions fifty years earlier. It was ions that interacted chemically with other ions in solution rather than with atoms or molecules. He asserted that these ions carried an electrical charge as they moved about and were the mechanism by which the solution conducted electrical current.

There was open and often bitter controversy during the two decades after he announced the discovery. The distinguished German chemist Wilhelm Ostwald stood at his side as a foreign savior and mentor during Arrhenius's most difficult times. Ostwald attested to the correctness of Arrhenius's thesis and he started a new technical publication as a vehicle for spreading and defending the ionic theory. They traveled the world of science arguing Arrhenius' theory. The two of them made a major presentation and defense of his theories in London in 1890.

Arrhenius's redemption at home began when the University of Stockholm's predecessor institution offered him a position as professor. The offer was made under somewhat humiliating conditions, which he bore with grace. He was quickly accepted by his colleagues and in two years was elected to the presidency of the school. In 1903, he became the first Swede to be awarded the Nobel Prize and it was in chemistry. He enjoyed the considerable recognition of other scientists continuously until his death in 1927.

It is necessary to look back further to understand the nature of Arrhenius' fall from scientific grace. Scientists had struggled to understand electrical conduction in liquids for the previous one hundred years. Svante August Arrhenius grew up near the world-famous State University of Upsala, Upsala, Sweden. As a bright youth, he turned his attention

early to experimenting with electrical conduction through salt solutions. When he entered the University, Professor Robert Thalen, the professor for physics, did not take him seriously and refused him the use of the physics laboratory. He did his experiments in the laboratory of Erik Edlund, Academy physicist.

Arrhenius made the fateful decision to continue with his interest in conductive solutions when he enrolled to study for his doctorate degree. He records the exact moment when he came to his principal discovery about conductivity in solutions. It was on May 17, 1883, that he entered a period of feverish work to write it down. He claimed that the salt molecules in solution divided into electrically polarized particles called ions. He confirmed for himself that he understood what was happening in salt solutions. His full statement of discovery claimed that these ions became the reactive elements for chemical behavior in solution and were also the agents for electrical conduction.

The relationship between theory and experiment was not well understood at this time in the development of modern science. Arrhenius had conceived a theory of ion formation and action. Professor Per Teodor Cleve, his doctoral advisor, was a distinguished scientist and the discoverer of the two metals: holmium (holmio was the Latin name for Stockholm) and thulium. Cleve considered theory to be something like Henry Ford's history, that is "bunk." Arrhenius's thesis dissertation was closely fought, and the outcome was only a partial victory for him. He received his doctorate degree of the fourth class, the lowest of four possible grades, and designated non sine laude approhatur, approved not without praise. He could not pursue an academic career at the university.

He responded to the setback by sending copies of his thesis to several prominent scientists outside of Sweden. One went to Wilhelm Ostwald, professor of chemistry at the Polytechnical School at Riga, in the Russian provence of Livonia, later Latvia. Ostwald found his thesis compelling and decided to help him. He traveled by train to Stockholm to meet and befriend Arrhenius. The result of Ostwald's mediation was the offer of a teaching position for Arrhenius in the Stockholm Technical High School (the Hogskola, later part of Stockholm University). The world of science was focused at that time entirely in Europe and North America. Ostwald's continued patronage of Arrhenius and his thesis gradually brought the world of science to terms with the existence of ions in solution.

Arrhenius gained the respect and fellowship of his colleagues in the Hogskola, a result of his increasing international renown. During this time, Arrhenius married Sofia Rudbeck, one of his pupils. The marriage lasted only two years and produced a son, Olav Vilhelm. Later he became deeply involved in the establishment of the Nobel Prize awards after the death of Alfred Bernhard Nobel in 1896 and in the adjudication of his will." His principal contribution to the establishment of the Nobel Academy was his insistence that the nomination and award selection procedures be international in their vision. The Academy elected him a member of both the chemistry and physics award selection committees. J. H. van't Hoff, a colleague in Holland, received the prize in chemistry in 1901, the first year of the chemistry awards. Arrhenius received it in 1903 after a thoroughly contentious candidacY His discovery of ionic disassociation in solution raised the significant question whether it was a physical or chemical discovery.

The physics award committee included Professor Thalen, from Upsala. It had no members from the Hogskola other than Arrhenius. The Upsala University members looked down on the Hogskola as an inferior institution. Thalen, who strongly influenced the physics committee's position concerning Arrhenius's candidacy, successfully persuaded the committee that Arrhenius's discovery was more properly assigned to chemistry thus absolving the physics committee of his candidacY Cleve, who had once refused any interest in the young Arrhenius's theories, now advanced Arrhenius's cause effectively in the chemistry award committee and was successful in achieving for him the chemistry award.

79) Calorimetry of beta decay in 1930's

Ludwik Kowalski (July 13, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

The book of C.B. Beaudette ("Excess Heat: Why Cold Fusion Research Prevailed," Oak Grow Press, LLC, South Bristol, Maine, USA, 2000) has already been used to quote an interesting story (see item 78). Another story from that book refers to the dilemma of beta decay energy which confronted physicists in 1930's. Calorimetry played an important role in that dilemma, as in cold fusion. Another similarity was in the apparent violation of the energy conservation law. The atomic masses of elements involved in beta decay were known and scientists calculated the amount of energy released in each transformation. The energy obtained from calorimetric experiments, however, turned out to be about three time smaller than expected.

According to Beaudette. "While those involved in the measurements thought this conflict meant that the missing energy got transported away by a particle presently unkown, most of physics refused the hypothesis and simply waited. They did this on a supposition that there might yet be an error in the heat measurements. In about twenty years, instruments were invented that were able to detect the neutrino. In proved to be the new particle that carried away the 'missing' energy. The calorimetric measurements and their corresponding hypothesis of a new particle were vindicated. This pattern of disbelief may be what is happening in cold fusion research where the measurements will be held in abeyance untill the nuclear answers are in."

Analogies, of course, have limited validity. The beta decay dilemma resulted from difficulties associated with detection of theoretically anticipated neutrinos, the cold fusion dilemma, on the other hand, resulted from the absence of an accepted theory. Calorimetric measurements of beta decay energy were always reproducible but calorimetric measurments of cold fusion are not always reproducible. This, according to Beaudette, shows "that the determining variables were under control" in beta decay experiments but not in the initial cold fusion experiments. Irreproducibility (see item 54 on my list) is not necessarily an indication that an experimental procedure is faulty. Fleischmann and Pons were the most qualified scientists in the world to perform electrochemical experiments for testing the hypothesis of excess heat.

Describing Fleischmann Beaudette wrote: "When he arrived [from Imperial College to Durham University], most electrochemistry was done by measuringthe current and voltage applied to the electrolytic cell. Fleischmann brought to the laboratory much more in the way of instrumentation. This improvement was widely recognized, and led to a rejuvenation of the field..... In 1967, Hills [chairman of chemistry department at Southampton University] invited Fleischmann to accept the position of Faraday Professor of Electrochemistry. His charge, when he arrived at Southampton, was to build a world class electrochemistry group. . . .

From 1970 to 1972 Fleischmann was president of the International Society of Electrochemists. In 1985.....he bacame a Fellow of the Royal Society of London, the most prestigeous honor for a scientist that England had to offer." What is the basis for accusing him to be a voodoo scientist? He came to the University of Utah to work with his former student, Pons. According to Beaudette "they published eight major papers on their measurements of anomalous power in scientific journals between July 1990 and 1995, and these have easily withstood the published criticism. ..... At Southampton, Fleischmann had gothered together components for an experiment in the early 1970s wherin hydrogen gas would be loaded into palladium metal in extreme amount. He had chosen the deuterium form of hydrogen for this experiment to see if nuclear fusion might be triggered." That was the hypothesis he came to test in Utah.

80) Secular Theology?

Ludwik Kowalski (July 14, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

As I wrote in item 3, criticism of CF was mostly focused on a speculative hypothesis (nuclear origin of excess heat) and not on the essential experimental fact (existence of excess heat) and on the methodology used by scientists who discovered it. In the Preliminary CF Note (1989) Pons and Fleischmann wrote: "It is inconceivable that this [excess heat] could be due to anything but a nuclear process. . . It is evident that [chemical] reactions are only a small part of the overall reaction scheme and that other nuclear processes must by involved. .....The bulk of the energy release is due to an hitherto unknown nuclear process." CF was declared to be pathological science (also in 1989) because reality of suspected nuclear processes has not yet been demonstrated. This is not very different from a situation in which critics rejected Galileo's findings because they conflicted with the existing view. The theory of circular orbiting was formulated (by I. Newton) long after Galileo's death.

According to (1), "to discard a well made observation is to violate modern protocol [accepted scientific methodology]. If widely practiced, such a course would quickly undo science. The most interesting and perplexing observations, though accurately measured, would have to be refused by the scientific community because their cause was obscure. Does this mean that any claim of observation must be accepted as worthy of scientific study? Certainly not. It means something quite different. It means that the controversy must center about the quality of the measurements and not about source or cause of the phenomenon. Karl Popper provides an escape from the difficulty of accepting into science an observation that went contrary to established theory. He asserts that science advances, not by proving theories correct or by defending them to the ends of the Earth, rather, by accepting (not adopting) experimental outcomes that contend with theory. His example was that the observation of a thousand white swans does not prove that all swans are white, but the observation of a single black swan undoes forever a theory that says all swans are white. ..... If conflicting data is prohibited from contention, then theories are no longer falsifible. Were it to enable such practice, **science would evolve into secular theology."**

Beaudette's book has many interesting observations, and quotes, pertinent to this important subject. That is why I recommend it to all those who are interested in history of science, and in philosophical aspects of its methodology. Another thing that impressed me was Chapter 14 describing work of those scientists who confirmed the initial excess heat findings of Fleischmann and Pons. The ERAB report, resulting in the blacklisting of cold fusion, was published only seven months after the discovery of excess heat was announced. This was unfortunate; many projects described in Beaudette's book, were far from being completed, or even conceived. What was the reason for not waiting another year or two before finishing the investigation? Was it a fear that producing a devastating report could become more difficult later because high caliber scientists started to be involved? Was it a rush to discredit the cold fusion field as soon as possible? Was it an attempt to protect science from charlatans? Was the ERAB panel trying to protect society from spending too much money on fraudulent projects? Such questions naturally come to mind in reading Chapter 14, especially about background and credentials of involved scientists.

81) Where are Theories ?

Ludwik Kowalski (July 18, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

This is another expiration based on Beaudette's book (1). In Chapter 16 he speculates about possible mechanisms of cold fusion. First he quote P. Hegelstein who wrote, in 1998, "that major outstanding theoretical problem is not how to elude the Coulomb barrier; and it is not how to account for anomalously low neutron emission rate. The big issue is, and always has been, whether a large energy quantum can be transferred efficiently from a nuclear reaction to new degrees of freedom associated with the surrounding environment."

Then he muses about a mechanism involving coherent phonons. Such phonons (quanta of thermal oscillation energy) excite atomic nuclei to energy levels at which reactions become possible. The process of excitation (accumulation of energy) is slow, presumably lasting several minutes or so. Beaudette writes: "The theorists suggested that the prolonged period when the nucleus is in an under-excited state makes the formation of stable reaction products possible." Personally. I can not take such speculations seriously; they conflict with what I know about nuclear processes. Only experimental findings of qualified scientists can be taken seriously, even when they conflict with accepted theoretical models. That is the essence of our scientific methodology, as emphasized in unit #80.

Later in the chapter Beaudette wrote;" It appears, at the time of writing, that the excess heat reaction is one that joins together two deutron atoms to make a single helium-four atom. In this process an energy of 23.8 MeV is released and transferred to the metal lattice as heat. What sort of 'joining' this reaction might be, is not known yet. It cannot be fusion as known by the high energy physicists, because that reaction generates lethal radiation and fast neutron particles that are not present in the excess heat data. It can not be the reaction of muon-induced (catalyzed) fission, because that reaction generates strong radiation not present in excess heat data. Several theorists suggest that the process might be the result of a multibody reaction, one that brings together more than two particles into the reaction process."

It is important to keep in mind that Beaudette is not a theoretical physicist; he is a retired electrical engineer interested in cold fusion. Earlier in the book he described a cold fusion experiment in which he participated as an observer. That experiment, at Stanford Research Institute, convinced him that generation of excess heat is real. He met with many cold fusion researchers at one of their international conferences. In my opinion his overall description of the cold fusion field is excellent and his book deserves a place in libraries, especially at high schools and universities. The level is appropriate for a person whose background is limited to an introductory physical science course.

In the Chapter 17 Beaudette summarizes the most interesting and puzzling data about nuclear transmutations taking place in cold fusion experiments. Once again he returns to the issue "secular theology." He quotes what John Huizenga wrote (2) about Fleischmann's mentioning of "fission of palladium." Fleischmann was, no doubt, unfamiliar with the fact I had researched nuclear fission for decades and had coauthored a book . . . on the subject. Knowing that the energy threshold for palladium fission was several tens of millions of electron volts, I had to conclude that Fleischmann was either joking . . . or exposing gaping holes in his knowledge of nuclear physics."

Let me mention that I personally know Huizenga and that the book he coauthored with R. Vandenbosch was a major reference in my own research. Huizenga was also the chairman of ERAB which produced the negative report about cold fusion in 1989. This report, well documented in (2), will remain an important historical event, no matter what the final verdict about cold fusion. Commenting on the above, Beaudette wrote: "That is the kind of comment that is skeptical rather than critical. Huizenga was not sufficiently intrigued to ask to see the data that had led Fleischmann to his supposition." Would my reaction to Fleischmann's claim be the same as that of Huizenga? It probably would. But I

agree with Beaudette that rejecting a claim (made by an experimentalist) because it did not agree with theory was not appropriate. Experimental findings conflicting with accepted models of reality should be scrutinized more carefully that other findings but conflicts with theories are not sufficient causes for rejections.

I do not know how Huizenga would have reacted to Muzino's findings if he had known about them. Would he have reacted as scientist, which I know he was, or would he have reacted as a politician? Should I contact him and ask what he thinks about new findings today? I do not think this would be appropriate; the last time we talked was more than twenty years ago. In the field of nuclear chemistry he was my teacher, not a personal friend.

82) Speculations of a retired physicist

Ludwik Kowalski (July 15, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

[P.S. On August 20 his paper became item #103 of this list]

A retired physicist (RP) sent me an essay in which he reflects on excess heat from thermonuclear reactions. He speculates that "cold fusion" takes place in tiny spots at which a crystal material (loaded with hydrogen) might be compressed to very high temperatures (millions K) by electromagnetic shock waves. In a letter accompanying the essay RP wrote: "Enclosed is a synthesis of my studies on problems associated with development of practical nuclear fusion. It contains elements of both 'hot' and 'cold' research. I hope that it can bring together these two feuding camps that jointly provide the research to bring, fusion energy reactors to reality. It is too important a goal for us to waste time and energy on a Hatfield-McCoy feud among physicists."

RP does not believe that cold fusion is basically different from hot fusion. He speculates that "data from cold fusion experimental reports indicate that nuclear fusion of atoms trapped in microstructures may be due to the imposition of external forces that generate compression waves. These waves compress lattice cells and heat the trapped deuterium atoms to fusion energy levels." In solid environments conditions are such that the energy released in thermonuclear fusion goes into random lattice oscillations rather than into radiation. Excess heat cannot be generated unless the Lawson criterion is satisfied. The essay elaborates on conditions under which that criterion can be satisfied in nanoparticles.

According to RP, who takes findings of cold fusion researchers seriously, it will be possible, at least in principle, to build a fusion reactor with the following properties:

a) It does not emit gamma rays and nucleons during its operation.
b) It does not produce radioactive residuals.
c) It is completely controllable and safe.
d) It is simple to build and operate.
e) It has high net power to weight ratio.
f) It can be scaled over a wide range in size and power.

A research program for achieving the goal is outlined; it refers to nanoparticles, to stabilization of electric arc with electromagnetic waves, to sonoluminescence, to plasma-acoustic shock waves and to other topics with which I am not familiar. To motivate inventors RP tells them that fusion reactors might exist on the sun surface. Referring to solar prominances he writes: "Solar loops rise from the surface of the sun [flares] to altitudes of 100,000 km. It would be expected that the temperature of the loop would decrease with altitude. Some loops have been observed to have their temperatures rise from 4500 K at the base to several million K at an altitude of about 10,000 km. This phenomenon has not been satisfactory explained." RP speculates that very high temperatures observed might be due to thermonuclear reactions. Nanoparticles, such as Carbon 60 (first discovered in solar spectrum), can possibly play an essential role in generation of excess heat. They are also essential in the conceptual description of his anticipated terrestrial reactor.

****

After writing the above I emailed it to RP. I also asked about the date at which his paper will be posted on his web site. He said that will try to do this before August 15. The URL of the web site, and the real name of RP will be inserted into this item later. His reply also contained comments shown below; I hope they will be useful. These comments are added with his permission. The RP wrote: " Your synopsis does not express central points of my paper as I would have presented them.

1. Hot fusion and cold fusion are closely related.

2. Neither approach, as now conceived, will produce a practical nuclear power device.

3. Knowledge gained from amalgamation of these two approaches suggests a new reactor concept that satisfies the "practicality" requirements.

a. no gamma or neutron emission
b. no radioactive byproducts
c. completely controllable and safe
d. simple to build and operate using current commercial components
e. high net power to weight ratio
f. scalable in size and power

4. Explanations are proffered for natural phenomena and experimental observations currently described as "anomalous"
.
5. Nanoparticles (uni-element molecules composed of 10 to 100s of atoms) that trap hydrogen are essential to this design. These products are produced commercially.

6. A schematic drawing of a conceptual design for a nuclear fusion device is presented and possible developmental experiments are described.

7. It would be practical for stationary, mobile, airborne and space vehicles.

8. This concept is particularly suitable for inclusion in scientific and technical courses.

9. The fundamental stabilized arc device (without nanoparticles) was built and operated by J. Yenser of Grumman Aircraft in the late 1950s.

Note: I think that putting items in the synopsis out of context may deter some people who are not well versed in the subject from reading the paper.

83) Disassociate cold fusion from unscientific claims

Ludwik Kowalski (July 22, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

On July 21, 2003 I posted the follwing Phys-L message about the cold fusion conferennce in Boston.

= = = = = = = = = =

Today, 7/21/03, is the last day to register for the ICCF10 (The 10th International Conference on Cold Fusion at MIT, August 24 to 29) at a reduced price. Go to the http://www.lenr-canr.org site, if you are interested. The list of submitted papers can also be seen there. Fleischmann himself is making two presentations. I am going because I want to meet him and others who contributed to an important scientific controversy. I also want to see cold fusion demonstrations; unfortunately, the list of demos has not yet been posted.

Contrary to what the leaders of our scientific establishment claim I no longer think that qualified cold fusion researchers are practicing voodoo science. Nor have I definitely concluded that chemically induced nuclear proceses are real. That is why I am going to the conference. Perhaps I will have something new to share after my return. But in September my priorities will shift back to teaching.

The phenomenon of pseudoscience is very real and society should be protected from those who exploit ignorance in order to benefit from unscientific claims and manipulations. Making money on therapeutic magnets, for example, is a scam; the healing effects of such gadgets have not been validated, as far as I know. The same applies to devices delivering electric energy from a so-called “vacuum.” How can society be protected from con artists without confusing charlatans with honest scientists addressing non-conventional topics? I hope this difficult issue will be addressed at the conference.

In my opinion cold fusion researchers should be as active in exposing pseudoscience as those who do so under the banner of mainstream science. How actively have they done this? How often do cold fusion researchers criticize each other? I suspect that this does not happen too often. I noticed, for example, that journals publishing cold fusion papers also publish papers devoted to topics of more questionable validity, such as perpetual motion devices, antigravity or hydrinos. Many cold fusion researchers probably disagree with such articles. But how often do they express this openly?

= = = = = = = = = =

The above message was also sent to two conference organizers. One of them responded in length and gave me permission to share what he wrote. The reply (in blue), is shown below; my comments (in red) are shown at the end.

= = = = = = = = = =

1) You asked: “What do you think about this issue?”

I do not think much of it.

2) You wrote: “In my opinion cold fusion researchers should be as active in exposing pseudoscience as those who do so

under the banner of mainstream science."

Why? They are not policemen. They are busy. Frankly, I don't see much point to spending a lot of time trying to judge what is pseudoscience and what isn't. People doing pseudoscience cause little harm, especially compared to people doing some types of conventional science such as plasma fusion.

3) You asked: "How actively have they done this?"

Not at all, as far as I know. I would advise them not to associate themselves with pseudoscience in either a positive or negative way. In fact, I do not think anyone should try to judge research he has not carefully investigated, for months or years. Cold fusion scientists are no more qualified to investigate something like "magnetic healing" than anyone else is. Only a medical researcher who has made a careful, honest, serious study of this topic has any business passing judgement on it. If no medical researchers have taken up this topic and performed experiments, then we have no way of knowing whether it is pseudoscience or real science. Experiments are the only standard of truth. You can never tell, a priori, whether a claim is true or false. Theory may predict a likely outcome, but only an experiment can produce an outcome (if you are lucky).

4) You asked; "How often do cold fusion researchers criticize each other?"

Always. Vociferously.

5) You wrote: "I suspect that this does not happen too often."

You couldn't be more wrong. I do not think you have any basis for this suspicion.

6) You wrote: "I noticed, for example, that journals publishing cold fusion papers also publish papers devoted to topics of more questionable validity, such as perpetual motion devices, antigravity or hydrinos."

Which journals? Infinite Energy perhaps, but not the Japanese Journal of Applied Physics. I do not think you can generalize. And how do you know whether hydrinos are pseudoscience or not? Unless and until someone tries to replicate the hydrino experimental results no one can judge that issue.

7) You wrote: "Many cold fusion researchers probably disagree with such articles. But how often do they express this openly?

Very often.

8) You wrote "The phenomenon of pseudoscience is very real and society should be protected from those who exploit ignorance in order to benefit from unscientific claims and manipulations. Making money on therapeutic magnets, for example, is a scam; the healing effects of such gadgets have not been validated, as far as I know."

You may be incorrect about that. There have been some surprising positive results from valid studies. See The New York Times SCIENCE, December 9, 1997, "Study on Using Magnets to Test Pain Surprises Skeptics. A small trial raises hope, but it is not the last word." by L.K. Altman, M.D.

Quote: "No one was more skeptical about using magnets for pain relief than Dr. Carlos Vallbona, former chairman of the department of community medicine at Baylor College of Medicine in Houston. So Dr. Vallbona was amazed when a study he did found that small, low intensity magnets worked, at least for patients experiencing symptoms that can develop years after polio. . ."

However, it is extremely unlikely these results will be replicated or confirmed because there is such rabid opposition to unorthodox ideas these days, so we will probably never know.

* * * * *

I agree with some of the above. In 5, for example, the word “guess” would be more appropriate than “suspect.” And in 6 I should have said “marginal journals.” I suppose that all cold fusion papers in JJAP were published because they passed the rigor of the strict “peer review” scrutiny. I was happy to read that cold fusion people often criticize each other work. That is a sign of health in science. The article you atached made me more receptive to the claims of Dr. Vallbona who said that magnets did reduce pain of many postpolio patients. I was not familiar with statistical studies conducted to verify the effect. To illustrate my point I should have chosen a less controversial example.

And what about item 2? My guess, based on some reading, is that con artists and charlatans do exist in every society. They often try to exploit simple people by asking them to buy things or to invest in projects. In that sense pseudoscience can be harmful. If I were involved in cold fusion research, and if my article were published in the same journal as an article about “hydrinos,” “quantum heeling” or “antigravity,” I would try to disassociate myself from these claims publicly. I would do this to protect my own image, not to be a policement.

Item 3 refers to validation of scientific claims. That is a big issue. To validate some textbook claims teachers often perform demonstrations. In addition students may be asked to validate things via laboratory work. But most claims are accepted on the basis of authoruty of textbooks and articles published in scientific journals. (In practice students accept what teachers say and teachers accept what scientists say.) Nobody has means and qualifications to verify everything by the way of experimenting. Existence of quarks, for example, can not verified in a typical university lab. That is why most of us wait untill experiments become 100% reproducible, as declared by recognized experts, before accepting new findings. You will see this issue addressed at my ICCF10 presentation.

84) From Physics Teachers on Phys-L

Ludwik Kowalski (July 30, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Let me share two URLs, and messages they generated in the “Hidden side of science” thread. Authors are physics professors at three universities, two from the US and one from Australia. All three belong to Phys-L, an Internet discussion list for science teachers. The list has about 700 subscribers, mostly physics teachers from 35 countries. I think that what Teacher 2 wrote about cold fusion is typical among educated observers.

Teacher #1 (JULY 24, 2003):

A Phys-L teacher, XXX, who occasionally comments on my cold fusion items (in private) shared interesting Internet resources about the often-ignored aspect of science.

1) The abstract from the first essay, by Brian Martin, is shown below.
The entire piece is at:

http://www.scientificexploration.org/jse/articles/martin/1.html

“**ABSTRACT:** Those who challenge conventional view or vested interests in science are likely to encounter difficulties. A scientific dissenter should first realize that science is a system of power as well as of knowledge, in which interest groups play a key role and insiders have an extra advantage. Dissenters are likely to be ignored or dismissed. If dissenters gain some recognition or outside support, they may be attacked. In the face of such obstacles, several strategies are available, which include mimicking science, aiming at lower status outlets, enlisting patrons, seeking a different audience, exposing suppression of dissent, and building a social movement.”

2) The second essay, by Daniel Drasin is entitled
"Zen and the Art of Debunkery." It can be fetched from:

http://members.aol.com/ddrasin/zen.html

Both are worth reading and thinking about. That is why I am sharing these URLs with the list. Any comments?

Teacher #2

I would say that anyone who is advising someone proposing an unpopular theory to scientists to "mimic science" is not coming at the problem from a scientific perspective.

And to argue that science has an "entrenched power structure," is only looking at half the situation, and then from a very jaundiced perspective. Science is conservative, as well it should be. New, revolutionary ideas need to be well established before they take over. If scientists ran after every chimera that came down the pike, they would seldom get anything done. But when something looks promising, even if it isn't likely, then lots of people will get active in "checking it out." That happened in the case of cold fusion, and what happened then is entirely characteristic of what happens in these cases. It happened in the case of the fifth force flap as well. That is, many labs try to reproduce the experiment, or design their own to test the idea, and at first many get corroborating results, but a few don't. Gradually the experiments are more and more carefully done and as that happens the number of corroborating results starts to decrease until only a few holdouts remain.

In the case of high T superconductivity, just the opposite happened, as time passed more and more of the verifying experiments were successful, as people learned the techniques better, and before long, the phenomenon entered mainstream science.

On the other hand, cold fusion has shown several of the characteristics of Langmuir's "pathological science." In addition to decreasing numbers of corroborating experiments, and a lack of alternative experiments (neutron flux measurements, etc.), there were lots of ad hoc explanations from the originators as to why this or that other experiment didn't work. The originators became more and more secretive and withdrawn. They refused to make their raw data available for examination, or to conduct their experiments in the presence of others, and everyone who got different results "weren't doing it right." It seems there was only one right way to do the experiment--change the slightest thing and it won't work, and they were not very forthcoming on the ways to fix the experiments.

It is seldom the case that some phenomenon can be detected by only one type of experiment and the circumstances have to be "just right" for it to work. It's not unheard of, but when it happens it puts and extra burden on the discoverers to be as open as possible in helping others to make their experiments work.

It is also crucially important for the discoverers to make every effort to find ways they could be wrong. Feynman's dictum applied here--first, don't fool yourself. If you aren't fooling yourself, you will not likely fool others. I don't think Pons and Fleischmann carried out this part of the "new science" regimen very well.

Of course, the "established" scientists are going to be reluctant to give up their pet theories, but, for the most part, not "unto the death." When something new is shown to work, scientists accept it quickly. Only a small rear guard might hang back or resist to the end. Something as revolutionary as cold fusion, with its incredible potential, is not going to be suppressed for long, if it is real. There is too much at stake. I doubt the folks in the high-energy fusion game will be too happy to see it come, but they are a relatively small part of the physics community, and if it worked, others would have flocked to the fold and we would be getting energy into our homes from that source by now, and the fusion research program at Princeton would have been shut down by now.

The argument that "establishment science" will do its damnedest to suppress any new ideas in order to protect its own "turf" is just nonsense put forth by the voodoo practitioners who are on the outside looking in. They are outside because they refuse to practice science as it should be done, instead insisting that they are a "little guy" being kept from success by "big science" and their monied backers.

Given the economic potential of this phenomenon if it exists, the "monied backers" would have flocked to the cause of cold fusion if there was any hope that it was real. In fact, I understand the Sony did provide some funding for Pons & Fleischmann at their lab in France for a few years, until they finally tired of ever seeing a return on their investment.

Obviously, many things that are presently thought to be not possible will be found to be possible in the future. I am not an expert on cold fusion and I cannot say with total confidence that it will never be proven to exist, but if it does, at some point someone will come up with the repeatable experiment that P&F apparently didn't have, will demonstrate it so others can repeat and redesign the setups and it will be shown to be real, and soon thereafter will enter mainstream science and within a short time after that will become a viable part of the world power grid.

But it's been, what, fifteen years since P&F burst on the scene? In that time they have gone from front page news to a scientific backwater. If they, or others have something, let them show it, with papers in the archival journals of record, and not backwater publications that might be more interested in publicity than scientific integrity.

That's my $0.02 worth. I have better things to do with my time than to read the ranting of an outsider, who, if your quoting of him is characteristic, has little if any understanding or appreciation of how science works. Its shades of Joe Newman all over again.

Teatcher #3

Teacher 1 quoted:

> the problem from a scientific perspective.

It is a pity that before writing your scathing reply you didn't take some time out to peruse Martin's paper (it probably would have taken less time than formulating your reply). Let's look at what Martin is getting at when he advises "mimicking or thodox science": Since mainstream scientists expect contributions to be in a certain standard format, then writing articles in this format may increase chances of success. Since submissions from institutional addresses are usually treated more seriously than those from home addresses, it may be useful to set up an institute even if it contains only one person! Alternatively, it might be possible to obtain an honorary position at an established institution, such as a university. There are a few open-minded departments that may be willing to provide a haven for dissenters." Whether or not that is "a scientific perspective", it's pretty good advice.

You continued:
> And to argue that science has an "entrenched power structure," is
> only looking at half the situation, and then from a very jaundiced
> perspective. Science is conservative, as well it should be.

You write "entrenched power structure"; Martin wrote "science is a system of power" which is not quite the same thing. Let's look at a little of what Martin wrote here. "Some types of interests are corporate, government, bureaucratic, professional, career, and psychological. In each case they can exert strong pressures on the direction of research and shape the response to challengers. Note that interests influence science without the necessity of conscious bias, since interests shape people 89s world views."

Certainly true, almost a motherhood statement. There's much more of interest as he develops this theme, with plenty of references given, but I won't overload this e-mail. For most of rest of your reply you go on about cold fusion: the points you make are certainly of interest but they are not relevant to your dismissal of Martin's paper, since he nowhere mentions cold fusion in that paper. So I'll snip a lot of your reply and preserve your final paragraph, which really got up my nose.

<snip>

> That's my $0.02 worth. I have better things to do with my time than
> to read the ranting of an outsider, who, if your quoting of him is
> characteristic, has little if any understanding or appreciation of
> how science works. Its shades of Joe Newman all over again.

Now, Hugh, Martin is a physicist; he is not an outsider. His paper is not a rant; it presents a well-argued and well-sourced argument. One may or may not agree with what he writes but he deserves to be read and not dismissed so cavalierly and with such scorn. I admit to a personal interest in this matter. Brain Martin did some teaching for me almost 30 years ago when he was a post-graduate student. That teaching was unconventional and successful. Since than he had spent many years understanding and appreciating how science works. Would that more of us had done the same.

Message #2

I plead guilty to not looking at the article. But the phrase "mimicking science" so turned me off that I couldn't resist the cheap shot. My perhaps misdirected arrows at Martin's article aside, I still think that my assessment of the cold fusion

scenario is accurate. That had nothing to do with Martin's article. I see CF as classic pathological science, as described by Langmuir (reprinted in Physics Today, October 1939, p. 36). I cannot say for certain that CF isn't real. I suspect nobody can. But I would guess, based on the number of the characteristics of pathological science it has exhibited, the odds against it are pretty long, and that was the main thrust of my rant. The quotation from Martin's article that Ludwik posted seemed cut directly from that mold. Yes, I probably should have looked at the article, but I was using a few spare minutes I had while waiting for a long printing job to complete, and didn't feel like taking on a major research operation, just in venting some spleen. If I have spattered some unjustified blood on Martin, I apologize.

85) From Mizuno's book.

Ludwik Kowalski (August 1, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Mizuno' s book "Nuclear Transmutation: The Reality of Cold Fusion" (Infinite Energy Press, Concord, New Hampshire, 1998) has already been referred to in my notes. It was translated and introduced by Jed Rothwell. I am going to summarize the book to capture what is worth remembering. Here is a general observation of this Japanese scientist. "The researcher must be sincerely interested and enthusiastic. Enthusiasm is what makes him willing to throw himself into work wholeheartedly. The key to good university research is to find the right topic and then concentrate on it. The university's job is to ensure an environment in which scientists can concentrate on their work, and ultimately return the benefit of their research to society. "

I think that Tadahiko was lucky to be well positioned (in terms of his experience at the Nuclear Engineering Department at Hokkaido University) to focus on cold fusion research as soon as the discovery was announced in 1989. He was working on targets used to produce neutrons. These were metallic foils saturated with deuterium. My own experience with such foils was limited but I remember how they were used. They were bombarded with accelerated ions to sustain nuclear reactions producing neutrons. The number of neutrons was proportional to the magnitude of the ionic current and to the concentration of deuterium atoms in the foil. Mizuno became an expert in preparing such targets. Such targets were made via electrolysis of heavy water solutions; the cold fusion technique used by Fleischmann and Ponds.

In 1971 he observed "excess heat" and speculated on its nuclear origin. Mizuno writes: "I had been performing exactly the same kind of experiments for more than twenty years, but I had completely overlooked the reported phenomenon." He is referring to what occurred in August 1978. The amount of water evaporated from an electrolytic cell in two weeks of continuos operation. was several times larger than what would be possible with the amount of electric energy received. In trying to explain what happened Mizuno was left with "only two possibilities: the electric current might has increased, rapidly electrolyzing all the liquid, or a large amount of [unexplained] heat caused the liquid to boil away. But at that time we could not imagine either of those scenarios, so we finally wrote off the incident as a mystery with no solution."

Mizuno became one of those who have studied various aspects of cold fusion for many years after the announcement of Fleischmann and Pons. Together with Akimoto he observed 2.45 MeV neutrons "at a level 10 - 20 times greater than background" but the rate of emission was much less than one per minute. Together with Azumi he observed tritium; the rate of production of that product was several orders of magnitude higher that production of neutrons. This alone was a good indication that a nuclear process responsible for neutrons and tritium must be very different from taking place in thermonuclear collisions (in hot plasma). The rate of generation of heat, calculated from the rate of tritium production, was shown to be too small to be observable. This was a good indication that the unexplained excess heat was not coming from reactions producing tritium.

In reading Mizuno's book one becomes aware that measuring excess heat was not the main priority; he and his colleagues were trying to demonstrate occurrence of nuclear processes in an electrolytic cell. But in one case the excess heat was extremely large; gallons of water evaporated in relatively short time would require more electric energy than was actually supplied to the cell. In 1994 Mizuno started using so-called "proton conductors." These are ceramic materials placed into hydrogen gas heated up to 1000 C. The electric field applied to a ceramic cylinder (via metallic contacts at the opposite faces) makes the protons (ions of hydrogen) drift through the material. Generation of excess heat was observed but the most interesting was production of new elements (alchemy).

Such observations have already been reported by other scientists but Mizuno and Ohmori were probably the first to

report on highly abnormal isotopic ratios. In 1996 similar reports were made, at a conference in Texas, by George Miley and John Bockris. Karabut's findings, described in the item 13 on my web site, confirmed these early observations. A discovery of new chemicals at a very low level of concentration always brings the issue of possible contamination; a discovery of highly abnormal isotopic ratios, on the other hand, can not be explained without accepting a nuclear process of some kind. In my opinion, isotopic shifts are the strongest arguments to support claims of nuclear transmutations. Asked what should a panel of experts (appointed again to investigate cold fusion) do I would answer "start by focusing on researchers reporting abnormal isotopic compositions." Competent mass spectrometrists should compare isotopic ratios from cathodes "before" and "after" the experiments.

Mizuno writes: "I immediately wrote up my results in a paper which I submitted to a number of journals. The submissions I sent overseas came back before long with referee comments turning them down. The reasons were: 1)Nuclear changes caused by chemical reactions cannot be accepted; 2) There is no theoretical explanation in the paper; 3) The writing and grammar were poor. I rewrote the paper and sent it again, but it was again rejected. In response to journals that had said there was no theoretical explanation, I wrote a theory, adding the proviso that it was strictly deductive (derived from data). They responded by rejecting the paper because the theory was too strange. In short, the policy was that no paper about cold fusion would be accepted under any circumstances, as I well understood." The paper was eventually accepted in Japan, after it was revised to satisfy comments made by the referees.

Much later Mizuno makes this interesting observation: " . . .it is not necessarily the case heat production means a [nuclear] reaction, an no heat means no reaction. There may be endothermic reactions that absorb heat instead of producing it. This is an important clue to understand the reaction mechanism. In many experiments until now, samples that did not produce heat were put aside and not analyzed. I believe important data may well have been overlooked when these samples were ignored." A panel of appointed experts (se above) should collect as many old samples as possible and measure isotopic ratios of all elements. A confirmation of abnormality could mean only one of two things; 1) Samples were deliberately fabricated to deceive; 2) Some nuclear processes were indeed taking place during cold fusion experiments. Recognition of chemically activated nuclear processes would mark the beginning of a new phase of investigation. In that phase cold fusion research would be treated like any other scientific field; it would no longer be labeled as pathological science.

Near the end of the book the author describes the 1996 theory of an Italian physicist E. Conte. Mizuno writes: "Up to now many theories to explain the mechanism of cold fusion have been proposed, but they have been inadequate. First came the ordinary D-D reaction hypothesis, then cracking (fractofusion), muon catalyzed, multibody, and neutron catalyzed fusion hypothesis. With each of them it was difficult to thoroughly explain all aspects of the phenomenon. Each of these hypotheses addressed a different aspect of the problem in an ad hoc fashion. Compared to the others up until now, Conte's theory is both simpler and more powerful because, by introducing a simple extension of the conventional quantum mechanical wave function, the theory accounts for all observed effects directly from the first principle. ....."

The theory is based on the assumption that, under right conditions, atomic electrons are able to get enough energy "to tunnel into the nucleus" and "combine with protons to form neutrons." The observed transmutations result from nuclear reactions induced by escaping neutrons. It is not clear to me what the word "tunneling" means in the context of electrons; the conventional wisdom is that an excess of energy leads to excitations or to ionization of atoms. As far as I know, a generally accepted theory of transmutations remains to be developed. On the other hand I am familiar with the K shell capture mentioned by Mizuno. It is "a form of radioactive decay in which one proton from inside the nucleus captures one electron from an orbit of the same atom to form a neutron." This process competes with the so-called "beta plus" decay; as a student I had a lot of difficulties with the theory of beta decay. The entire cold fusion field is still at the embryonic stage. Will it ever reach a stage at which at least one nuclear transmutation is 100% reproducible? (By this I mean a stage at which a competent scientist is able to demonstrate the effect in any well equipped lab.)

Appendix 1 and 2 contain two publications of Mizuno et al. In the second publication the authors report unusual isotopic composition among many transmutation products found on the cathode of their electrochemical cell. They write: "The anomalous isotopic distribution of these elements shows they do not come from contamination. For example, natural copper is 70% ^{63}Cu and 30% ^{65}Cu. But the copper found in the cathode was 100% of ^{63}Cu, with no detectable levels of

Cu. Natural isotopic distribution varies by less than 0.001% for copper." Either their data were fabricated to deceive or they are real. What else can it be? My own experience in working with a mass spectrometer tells me that such instruments cannot possibly be responsible for "an honest error" of confusing 30% with 0%. In the book Mizuno tells us that samples were examined in several laboratories specializing in mass spectrometry.

86) Pseudoscience in Russia

Ludwik Kowalski (August 1, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

In unit 56 and 57 I shared what I read about con artists pretending to be scientists in America. It seems they have been much more aggressive in the former Soviet Union, and in the new Russia. I am rereading Kruglyakov's 2001 book "The Highwaymen of Science." The author has already been introduced in unit #10. What follows is my own translation of a letter sent by Kruglyakov to the president of the country V.V. Putin . The Russian text with signatures of three physicists (Alexandrov, Ginzburg and Kruglyakov, representing the Russian Academy of Science) can be found on pages 301 to 303 of the book.

"Dear Vladimir Vladimirovich:
Your goal, as you stated, is to recreate a strong and flourishing Russia. You know that the country's existing scientific potential must be used to accomplish the task. We want to assure you that the Russian Academy of Science is ready to contribute. At the same time we want you to know that the influence of pseudoscience is growing in our country. This is so dangerous that the Russian Academy of Science had to create a special commission to oppose pseudoscience and falsification of research. Democracy and freedom of speech, great successes of the post-Soviet period, in the absence of feedback control mechanisms, started to produce some negative results..... "

It occurred to me, after typing the above, that an English translation of this important letter probably exists somewhere. The Internet search engine, Google, was used to find what Kruglyakov wrote (in Skeptical Inquirer magazine Volume 26, Number 4, July/August 2002) about pseudoscience in Russia. The article can be found at:

http://www.csicop.org/si/2002-07/dangerous.html

It is a good summary of Kruglyakov's book; the letter to Putin is mentioned at the end. The letter is essentially a short version of what is written in the article. After realizing this I stopped translating and decided to use quotations extracted from the Skeptical Inquirer article. My own comment is added at the end.

****

"The end of the twentieth century was marked by a boom of astrology, mysticism, and occultism in many countries. In the USSR (during the last years of its existence) and then in Russia the situation was even worse in a sense. The system's collapse and the wreck of old ideals-along with the absence of new ones-caused many people to hope for some kind of miracle. The mass media contributed to this tendency. Through their irresponsibility, pseudoscience has filled newspapers, magazines, radio, and TV.

In recent years a new phenomenon has arisen. Pseudoscience has become a powerful, well-organized force. Over the last decade in Russia, about 120 academies have appeared, many of which don't deserve the name 'academy.'

Some of them give their stamp of approval to professionally inadequate doctors of science in various fields. Others do the same in pseudoscientific disciplines, giving diplomas to astrologers, UFOlogists, and others of the sort.

In Russia, even research institutes with pseudoscientific tendencies have appeared. I'll give only two examples: the International Institute of Space Anthropecology and the International Institute of Theoretical and Applied Physics. The

first has even managed to attain state accreditation with the help of the Russian Ministry of Science. The second has received financial support both from the Ministry of Science and the Ministry of Defense for the well-known swindle of torsion fields.

Peaceful coexistence between science and pseudoscience is impossible. From time to time, science attempts to unmask pseudoscience. The latter fights back with fierce hatred. Pseudoscientists are anxious to settle accounts with the Academy of Science, because the Academy is a great obstacle to these newly half-baked 'scientists.' Here are a few quoted statements of such people: . . . Thus pseudoscience predicts the full breakdown of science unless the scientific paradigm is changed. Meanwhile, according to a statement of academician Z.I. Alferov, recently awarded the Nobel Prize, '. . . the crisis in quantum physics is not observed. For the most part in the physics kingdom, it is calm now.'

Here is what one of the main theorists of the so-called science of torsion fields, 'academician' G. Shipov said: 'Now there is no doubt in the existence of telepathy, levitation, clairvoyance, retrovision, or that energy of consciousness plays some certain role in physical processes.' And since science does not recognize this, therefore, 'official science lags behind the new developments.' . . . Here is another case, involving M.D. Maley, chairman of the Interdepartmental Commission on Scientific and Technical Problems of the Industry of Defense of Security Council of the Russian Federation. The purpose he pursued looked rather reasonable: 'From the viewpoint of the Security Council, our task is to filter correctly the basic directions and orient the present and future management of the country with respect to a launching position of Russia in this scientific-technical revolution.'

To prepare for scientific breakthroughs, Mr. Maley created a 'Large State Research Center.' This is praiseworthy in itself; a high-ranking government official facilitates the development of a science. Alas, when one hears the purposes, you can't help being horrified at the ignorance of the official: 'Replacement of the concepts of quantum physics by neutron physics, vacuum as emptiness by the concept of neutrino fields is in prospect for us..... We have some works at the R&D [research and development] stages that contradict common sense and cannot be described by any equation.' . . . Astrologers, claimants of extrasensory powers, and newly appeared 'scientists' of other 'professions' more and more actively push themselves through into the State Duma, ministries, and even into the President's circle. Here are recent examples: This entire swindle is apparent to any physicist at once. Nevertheless, I had to carry out the official investigation. It revealed that Mr. Grabovoy never took part in tests of nuclear weapons in Semipalatinsk. Therefore, he did not test 'a crystalline module' there. At the same time, it was revealed that this 'doctor of technical and phys-math. science' has never defended any theses. In lists of the Italian Academy of Science, 'academician' Gravovoy was never mentioned. It is sad that the governmental Rossiyskaya Gazeta misled its readers; alas, not for the first time. . . .

Alternative medicine has dramatically developed. It is attracting numerous unscrupulous swindlers, robbing sick people who cannot find help from traditional medicine. New medical devices claiming to cure patients of any illness are appearing on the market. A device called 'New Cardiomag' recently became available at a price of only 500 rubles (about $16). It supposedly helps with hypertonia, ischemia, arterial hypertension, stenocardia, and headaches. One might question the honesty of developers of the device since one of them, doctor of medical science A.P. Naumov, has written in an advertisement for the 'Cardiomag' the following: 'This is an ecologically pure autonomous source of gravitation field, pulse bipolar current, and direct magnetic field with special energy characteristics (Isvestiya, March 14, 2001).'

It is incomprehensible why the Academy of Medical Sciences keeps silent about such fraud. It is time to express its opinion about that. The ever-growing activities of pseudoscience attempt to get money from the government, consumers, and industry while avoiding the standard procedures of review by experts. There are many examples of pseudoscientists managing to get money from state sources. The most well known is the swindle based on so-called torsion fields. In addition, there are some 'studies' on anti-gravity, and on transmutation of elements with an attempt to obtain gold (not involving the known method of nuclear reactions but instead a modern version of alchemy).

In such an atmosphere, at the end of 1998 the President of the Russian Academy of Science, academician Yu. W. Osipov, arranged a special Commission Against Pseudoscience and the Falsifications of Scientific Studies. One of the commission's very first actions was to prepare a special appeal that was considered and accepted by the Presidium of the Russian Academy of Sciences. This appeal was published in many Russian mass media outlets.

Members of the commission appeared many times in newspapers and magazines and on radio and TV, addressing the government with suggestions. I think I can say that this commission and its work with the mass media resulted in some corrections of the situation. Some allies appeared among journalists, astrological forecasts vanished from some newspapers, and some science sections appeared. In addition, scientists more frequently were asked to be guests on TV programs. However, these are only small steps. A victory over pseudoscience is still far away."

****

Kruglyakov's book contains his March 16, 1999 paper entitled "On Problems of Opposing Pseudoscience." That paper was read and discussed at the meeting of the presidium of Russian Academy of Science. One of the academicians said: "It is true that wild and hard to accept hypotheses are sometimes published today; for example, that our planet is hollow inside. Such ideas should not be published. I am referring to existing but not yet understood phenomena; they might be erroneously characterized as false." In reading this observation, made by academician A.L. Jashin, I thought about some cold fusion reports. Kruglyakov's commission work is badly needed in Russia and I hope it will be successful. But his book categorizes cold fusion as pseudoscience. That is a big mistake, in my opinion. As a nuclear physicist the author is probably aware that the cold fusion situation is no longer the same as it was in 1990. But he writes as if cold fusion researchers still believed that excess heat is produced from conventional thermonuclear collisions.

In a review of Russian cold fusion conferences (pages 306 to 310) he prefers to ridicule rather than address the claims made by several researchers. What I have in mind is generation of helium (commensurable with excess heat) and unnatural isotopic ratios among the reaction byproducts. Instead of apriori dismissing such claims a physicist should examine the evidenceand ask for a demonstration. What was the basis for saying that Sovvatimova was "inspired by Bazhutov's model?" She presumably reported experimental data. Instead of being ridiculed she should have been invited to repeat the experiment in the presence of qualified scientists. Her work should either be dismissed or accepted on the basis of what was observed. The same applies to the claim made by Kaldomasov. What is wrong with trying another liquid? Several American workers reported excess heat and transmutations from an electrolytic cell based on common water.

What does cold fusion research have in common with astrology, mysticism and occultism? By the way, Edward Kruglyakov is laboratory head and deputy director of the largest institute of the Russian Academy of Sciences (Budker Institute of Nuclear Physics). Academician Kruglyakov is the State Prize (1986) and Artsimovich award (2001) winner. Born in 1934 he is a graduate of Moscow Institute of Physics and Technology. He is certainly not a pseudoscientists. But his attitude toward cold fusion does not look very scientific to me.

87) Targeting a “straw man”

Ludwik Kowalski (August 5, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07055

My first opinion about cold fusion was based on Huizenga’s famous ERAB report and on what was written about the phenomenon in 1989 or 1990. Only recently did I realize that the criticism of Fleischmann and Pons was, in part, an attack on a straw man. Who was the first to introduce the term “cold fusion?” The essence of the initial announcement was the existence of unexplained excess heat; and the idea that it can not possibly be caused by a chemical reaction. But the scientists were attacked as if their main claim was observation of a conventional thermonuclear reactions at ordinary temperatures. That claim became the proverbial straw man. How can such reactions happen despite the coulomb barrier? Where are neutrons and protons always accompanying thermonuclear reactions? Where is tritium? Absence of such byproduct was then used to discredit the real discovery.

I knew Huizenga personally and I respected him as a scientist. But by leading the attack on a straw man he was acting more as a politician than as a scientist. Is he aware that a large number of researchers have now confirmed accumulation of helium in heat-generating experiments? And that the rate at which helium is produced is roughly commensurable with what would be expected from any kind of D+D fusion. Would he reject such findings because we still do not have a theory? Unfortunately, I do not know how to answer such questions. I was tempted to contact him recently but decided against it; Huizenga is probably very old now. His “successor,” Robert Park, seems to ignore new findings; who appointed him to be a spokesman for APS? Park uses the same arguments against cold fusion as Huizenga used 13 years ago.

The term cold fusion was partially responsible for the staw man arguments. My own attempts to stop using this term failed; this is reflected in essays posted at my web site. Last night I learned that Edmund Storms also thinks that the term cold fusion will eventually prevail. Here is what I wrote to him and how my e-mail message was answered:

Dear Dr. Storms:
I agree that the term “cold fusion” was partially responsible for bad reception of the discovery of excess heat in 1989. The alternative, LENR-CANR, is gradually replacing the undesirable phrase. But it is difficult to use this acronym in a lecture or in a conversation. First it is hard to pronounce, second, it is awkward to use. if it was up to me I would use an alternative. Suppose that the LECAN acronym is used as a single adjective, as in LECAN field, LECAN reactions, LECAN phenomena, LECAN opponents, etc. This is less rigid and easier to pronounce. Formally LECAN would stand for a long adjective: “Low-Energy-Chemically-Activated-Nuclear.”

I am just sharing an idea; it is probably too late to make a change. Am I the only one who is not happy with LENR-CANR? (You probably know that about 40 years ago the term “low energy nuclear reactions” was used to describe transmutations induced by projectiles whose energies were up to about 20 MeV. Later it became 200 MeV, or something close to it.) I am looking forward to meeting you in person at the ICCF-10 conference. Best regards, Ludwik Kowalski

Dear Ludwik,
The long form, LENR-CANR, is not intended to be used in conversation, only as the name of the web site. I frequently just use LENR, which is adequate. However, everyone knows what "cold fusion" means and it will cease to have the bad
connotation as the idea is accepted. I suspect, "cold fusion" will be the name most people will use in the future. See you at ICCF-10. Ed

88) Rejections of cold fusion publications

Ludwik Kowalski (August 5, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

On November 30, 2002 a nuclear scientist, E. Storms (1) sent a letter to the editor of Scientific American. Here is the content of that letter (2).

Dear Sir:
Your analysis in the December issue about why science is neither respected nor understood by the general public I found to be very much to the point. Those occasions when science accepts claims that are later found to be false clearly give science a black mark. Unfortunately, in an effort to avoid such embarrassment, science also rejects claims that are later found to be true. I ask you, which is the greater threat to science and mankind, accepting a claim that can have no possible benefit or rejecting a claim that can have great benefit?

I could offer many examples of how good ideas have been rejected in the past, but I would like you to consider one very important claim that now has almost universal rejection, yet is supported by a growing body of data. As a scientist, I was trained to judge the reality of nature from good data based on replicated experiments. Yet, I find that the scientific community increasingly bases what is real on the opinions of a few respected journals and academics using theoretical arguments, regardless of what is being discovered by other scientists operating in the real world. How is the general public expected to respect science when it does not follow its own stated rules of evidence?

The discovery I would like to use as an example of this double standard is what is called LENR or low energy nuclear reactions. This has also been given the very inaccurate name of cold fusion, a name that now causes rejection and ridicule. This ridicule comes from people who have no understanding about what is now known, yet their opinions are accepted as fact. Is this the way science is supposed to operate?

If you wish to be true to your stated wish to make science more respected, I suggest you educate yourself about this important phenomenon by reading information available at www.lenr-canr.org. There you will find over a thousand publications that support the reality of such anomalous nuclear reactions, as well as several reviews in full text that answer important questions raised by skeptics in the past. Serious scientists rejected "cold fusion" in the past for good reason. These reasons no longer apply. If science cannot correct a past rejection, then what good is the scientific method? Can anyone respect a scientist who cannot change his/her mind after being presented with better data? Respectfully, Edmund Storms, Ph.D.

Why was this letter not published in Scientific American? To understand it one must be familiar with the highly unusual polarization of the scientific community on the issue of LENR that occurred after 1989. In my opinion, claims made by prominent scientists should be presented to the general public, even when such claims are questioned by other prominent scientists. Scientific American has been doing this for over one hundred years. But the current editor of that journal, John Rennie, decided not to publish the letter. Here is the reply:

Dear Dr. Storms:
Thank you for your e-mail proposing that Scientific American reevaluate the status of LENR-CANR research and consider publishing an article on the subject. As you suggested, I did look over a number of the offerings at www.lenr-canr.org. Unfortunately, I still don't see evidence in those papers, or in the mainstream physics literature, that LENR-CANR has achieved any significantly new level of credibility in the eyes of the general

physics community. The site does point to a large number of publications that ostensibly offer evidence of the phenomenon, but sheer numbers of papers is not sufficiently compelling--as I'm sure you know, even the creationists can point to thousands of "publications" and "scientists" seemingly supporting their position.

I noticed that the LENR-CANR site, on its page appealing to readers to "help spread the word" about the phenomenon, described Scientific American as having "gone far out on a limb opposing cold fusion. They, along with the leaders of the American Physical Society and the Department of Energy, have made their institutions into bastions of opposition to cold fusion." We at Scientific American don't feel that we've gone out on a limb in criticizing cold fusion harshly in the past. As for our being a bastion of opposition to it, I don't think we have an intractably committed position. If LENR-CANR can be demonstrated satisfactorily for acceptance by the physics mainstream, we would be more than happy to publish more favorable articles about it. Your problem starts with establishing more credibility in their eyes, not ours. Sincerely, John Rennie

Referring to the above, Jed Rothwell (the manager of the LENR-CANR web site) wrote:

Rennie has dismissed 2,000 papers, including research from laboratories such Los Alamos, the Naval Research Laboratory and Mitsubishi Heavy Industries, mainly by equating these papers with creationism. Waving your hand and saying that "X is like creationism" does not make X resemble creationism. Cold fusion is an experimental finding, which is completely unlike creationism, or actual evolutionary theory, for that matter. It is not based on theory or an interpretation of the fossil record, but rather on long-established laboratory instruments and procedures in calorimetry, mass spectroscopy and so on. The only way to disprove cold fusion is to find technical errors in the techniques that are applied by specific cold fusion researchers.

The editor of Scientific American responded:

The people you need to convince about the scientific credibility of cold fusion aren't journalists. They're professional physicists who review submissions for respectable technical journals. If you can convince mainstream scientists that LENR-CANR is real and significant, magazines like Scientific American will drop into line.

In other words, he is saying that Scientific American is not a technical journal; its decision to silence a high caliber scientist was bureaucratic rather than scientific. I can understand this. But I do not think that Storms' letter would do any harm to the general public. On the contrary, it would promote interest in science. I can see the dilemma of the editor. He thinks that it is not his job to evaluate experimental findings; his own scientific background is likely to be different from what is needed. The editor would not publish an article on a LENR-CANR phenomenon unless it had been validated in purely scientific journals. But editors of leading scientific journals in the US also reject LENR-CANR papers. Let me illustrate this. In 2001 E. Storms wrote a review of the entire field (4) and tried to publish it in four journals: Physical Review, Review of Modern Physics, Chemical Review and Journal of Electroanalytical Chemistry. He was not successful. The disappointed author wrote:

The editor of the first journal said the Phys. Rev. does not publish reviews, although this is not true if the subject is to their liking. The editor of the second journal rejected the paper with the comment 'Cold fusion is a classic example of pathological science. I will certainly not publish articles supporting its disproven claims.' Three of four reviewers of the third journal rejected the paper because they did not think cold fusion is real and could not trust me to be unbiased in arguing this belief. The fourth journal rejected it because 'the subject was not appropriate for the journal.' Submission was done in series, with a new journal chosen after a rejection.

What is my own position on the situation in the cold fusion field? I used to say that the field is pseudoscientific. This was based on what I read from books, such as (6), and articles published shortly after the discovery of excess heat was announced by Fleischmann and Pons. But I am no longer comfortable with this position; recent reviews of the field, and numerous publications, seem to be very scientific to me. But I am still not convinced that the phenomena are real. Being an outsider I am waiting for a new evaluation of cold fusion phenomena by a competent panel of appointed scientists. I am also waiting for a single 100% reproducible demonstration of a nuclear effect resulting from a chemical process. Most physics teachers, like myself, are not equipped to conduct sophisticated research; that is why leaders of our

scientific establishment (scientists at APS, editors of major scientific journals and administrators of research granting agencies, such as NSF) should support calls for a new evaluation of the controversial field. My own call for a new evaluation, expressed in a letter to the editor of Physics Today, has not been published. That letter was prompted by the APS ethical guidelines article published in Physics Today. I wrote:

....As a physics teacher I am confused by the situation. What should we tell students when they ask about the discovery of Fleischmann and Pons? Most teachers have no time and no means to validate claims made in the area of "cold fusion," and need guidance. An objective summary of what has been done in that field, in the last ten years, would help us to describe it correctly. The issue is not only scientific; it is a topic of general interest. Most educated people know about the "cold fusion episode" and opinions about it are divided. Some say it was "a fiasco" while others say it was an "important discovery." How should teachers address this topic in the context of "public affairs between science and society," or in the context of discussing "institutional support for new ideas and innovations?"

After waiting several months I asked the editor about the status of my letter. The reply was: "So far, I have a split decision on the possible publication of your letter. I expect soon to have a tie-breaking input from a third reviewer. I will let you know as soon as I have a firm decision. Thank you for your patience." I was encouraged. But several days later I was informed about the rejection of my letter. On July 3, 2003, the editor, Dr. Hanna, wrote: "Our decision, after some valuable discussion, is not to publish your letter. Thank you for writing and for your interest in Physics Today." Curious about the rejection arguments I asked for the copies of reviewers' reports. Here is the reply to that request:

Thank you for your inquiry. Please let me explain. I know that scientists who submit articles to peer-reviewed scientific journals expect reviewers to give them a critique of their letters. Physics Today is not, in the strictest sense, a peer-reviewed scientific journal; it is, instead, a special-interest magazine for physicists. Generally, my reviewers are staff writers and editors (all physicists) who may give me little more than 'thumbs up' or 'thumbs down' on a letter. As a rule, we do not give out the specific comments of the reviewers, because we consider them to be internal business. Thank you for your inquiry. I hope my explanation has helped.

Likewise, my short note about the new situation in the LENR-CANR field was rejected by The Physics Teacher. The editor, Karl Mamola, wrote me:

Our editorial staff has completed its review of your manuscript 'On Reproducibility of Data in Cold Fusion Experiments.' The process included consultation with two of our referees. I regret to inform you of our decision not to publish the paper. The first referee offered only brief comments: 'I don't think The Physics Teacher is the right journal for this paper. Most readers of this journal are in no position to judge these rather esoteric matters. Indeed, most teachers wouldn't know what the fuss is all about.' In the light of the referees' comments and of our own careful reexamination of the manuscript, we believe that TPT readers would not be able to make sufficient use of the paper to warrant its publication. While we are not able to use the manuscript you submitted, we appreciate having had the opportunity to read it and we are grateful for your continued interest in The Physics Teacher.

The second referee wrote:

I must recommend against publication of this paper in *The Physics Teacher*. Despite the claim of 'helping us teachers,' the paper seems actually to be an attempt to have a serious journal endorse cold fusion as a research field to be taken seriously. The pages of *The Physics Teacher* are not the appropriate place to make such arguments. ..... Even if there were some validity to the now 14 years' worth of attempts at cold fusion (I haven't heard of any), *TPT* is about the last place in the world for this to be published.

I do not know why a person not familiar with new findings, such as abnormal isotopic ratios and commensurable accumulation of helium, was chosen to referee my note. How should rejections of LENR-CANR publications be interpreted? They reflect the situation in which, as observed by a friend (5), biasing prevents people from being objective readers of the book of nature. This, however, does not refer to the editor of Scientific American; I consider him to be a journalist with s scientific background. Only scientists read and interpret the book of nature. The friend

wrote: “If we become certain that LENR doesn't exist, then when Schwinger and Storms and McCubre later present positive evidence for it . . . it just proves their incompetence. Since we know that LENR is bogus, then positive replications are demonstrations that those labs are incompetent. Note that no amount of positive evidence can *ever* be convincing. A preexisting conviction acts as a mental filter.

But where did such a preexisting conviction come from? In science it's wrong to first adopt a viewpoint and then to use the selection of evidence in order to support that viewpoint. Politicians do it. The legal system is based on it. Science is totally different: a bend-over-backwards search for the truth rather than a defense of a an existing position during a debate. If one claims to be scientific, yet also adopts a position not based on evidence, then that is pseudoscience. It is a particular form of pseudoscience known widely as ‘Cargo Cult Science.’ One essential element is missing: the no-holds-barred search for truth.

Why would anyone ever adopt a firm position and start selecting evidence? One reason is ridicule. It's a known phenomenon in sociology. Once a person has ridiculed a particular concept, that person is trapped. They've surrendered their objectivity and their self-image is on the line. A huge conflict of interest arises because, if their ridicule was wrong, it's an embarrassing error of major proportion, and they've opened *themselves* up as a target for ridicule. Once such a conflict of interest exists, only an overwhelming amount of contrary evidence can ever sway them into reexamining their position. The practice of ridicule very often leads to a firmly closed mind, so scientists should avoid such behavior at all costs.”

I find these observations interesting; ridiculing political opponents is commonly used to avoid real issues. Robert Park and Edward Kruglyakov also use this trick in writing about cold fusion. They lean on arguments that were convincing in 1993 but not convincing in the context of recent findings. People like Park and Kruglyakov are spokesmen for the bureaucratic component of mainstream science. The editors of many journals find it safe not to be in conflict bureaucrats. It is significant, for example, that John Rennies wrote: “I did not see evidence . . . of the level of credibility;” he did not write: “I do not see evidence supporting the existence of cold fusion phenomena.” Why would anybody look at the LENR-CANR web site for the evidence of “credibility?” It is a site to look for the evidence of “existence” of cold fusion. Instead of ridiculing cold fusion its opponents should have a web site criticizing new findings in that field.
Such site would be very useful to those who are not able to read the book of nature in sophisticated laboratories.

Only highly trained scientists using expensive equipment are in a position to validate cold fusion claims. We read their papers and form our own opinion. This fact should be recognized; the situation was very different one hundred years ago. Neither editors of Scientific American, nor we, physics teachers, can perform experiments with sophisticated mass spectrometers in ultra-clean labs. In this new situation the role of a journal like Scientific American becomes even more important than in the past. I have no idea why Storms’ letter was not published. The author is a recognized authority in nuclear chemistry, a research veteran from Los Alamos, one of the best nuclear technology laboratories in the world. Why was he silenced by John Rennie?

P.S. Let me end with a positive indication. This morning I was informed that my letter to the editor of The Physics Teacher has been published (6).

89) Hydrinos again:

Ludwik Kowalski, <kowalskiL@mail.montclair.edu>
Montclair State University, Upper Montclair, NJ, 07043, (8/11/03)

Norm Winningstad, a retired engineer and businessman, probably read what I composed about hydrinos in unit 57. That is why, I suppose, he sent me an e-mail message with an attached pdf file. That file contained a recent article from Journal of Physics published by R. Mills and P. Ray (J Phys. D: Appl. Phys. 36, 2003, pages 1535 to 1542). The title of the article is "Extreme ultraviolet spectroscopy of helium-hydrogen plasma." I see that the authors do not use the term “hydrino,” the term “fractional Rydberg states of atomic hydrogen” is used instead. Am I right on this? Did the authors really demonstrate the existence of such states?" Unfortunately, I can not answer this question by myself; my background in spectroscopy is limited. The topic is likely to be familiar to astrophysicists; sun is made from a mixture of hot hydrogen and helium. Hopefully, some experts will evaluate the paper for people like myself. By the way, the role of authority in science is not at all minor; we depend on each others expertise.

The unit #57 on my list was triggered by a theory presented by Mills. That is why I wrote that existence of hydrinos is based on theoretical arguments rather than on confirmed experimental data. Was I wrong? It depends on how the new article will be evaluated by experts. My guess is that raw data will be confirmed but the interpretation will be challenged. Perhaps competent spectroscopists will find less exotic explanations of lines observed by Mills and Ray. In any case, I see no reason to associate hydrinos with cold fusion. Mills himself wrote (in a recent article on excess heat) a “hitherto unknown exothermic chemical reaction“ is responsible. In other words, he does not think a nuclear process is involved.

****

Journal of Physics, as one can see at http://www.iop.org , is an electronic journal in which articles are said to be peer-reviewed. But what does this mean in practice?
To answer this question look at the following e-mail message. BLP stands for the research lab headed by R. Mills. Their web site

http://www.blacklightpower.com/theory.shtml

has links to published papers. Explaining how to search this site the author writes:

“Ludwik, I did a little digging, and I would recommend you go to the BLP web site, and click on the left on Technical Papers. Then at 2nd from the top, click on Abstracts. Then go to #1, about the NASA report. Go to # 45, which has a Journal of Applied Physics peer-reviewed article (2002) Vol. 92, No. 12, pgs. 7008-7022. #49, Journal of Molecular Structure. #62, IEEE Transactions on Plasma Science, Vol. 30, No. 2 (2002) Pgs. 639-653.

I will be the first to admit that it is frustrating to have most of the new articles listed as ‘submitted’ or ‘in Press.’ I assume the first means it is **not peer-reviewed yet**, and the second, that it is **peer-reviewed, but not yet printed**. You will note the list is long, largely because of the crescendo of writing lately at BLP as a result of their experimental work being fruitful, due to years of optimizing. I suspect the reason that they do not name the journals where the papers were ‘submitted,’ or where they are ‘in press,’ is because BLP experienced having papers through the peer-review process, only to have **the editor over-rule his own peer-review panel**, just before printing, because it was leaked to Park and/or Zimmerman, who blew into the editor's ear about how foolish he will look, if he publishes some thing contrary to Schroedinger's Equations.”

I do not know what “printing” means for the Journal of Physics; it an an electronic journal. What would prevent an

author from posting an article which was submitted but not yet reviewed? Or what would prevent an author from posting an article which was peer-reviewed but not approved by the editor? I wish the article of Mills and Roy were published in Physical Review, or another traditional journal. In that case seeing it on paper would mean that both the referees and the editor decided that the paper is reliable.

****

Browsing the Internet I found this web page: < http://www.phact.org/e/blp.htm >. The title is "BlackLight Power - do they have something significant?" Let me quote some pieces. Referring to Mills' theory somebody wrote:

Eric, I have a Ph.D. in physics and I have went through the mathematical and theoretical derivations of Mills in the book he published. In summary his results are incorrect. This is what he does.

1) He starts out with the 3-D shroedinger equation to make things look respectable.

2) Then he solves the z, theta, portions by separation of variables the usual way to make it look even more believable.

3) Then a miracle happens and he assumes that he can solve the radial, r, portion by assuming that r is continues and not quantized.

4) He uses this solution to rewrite all of his Quasi Quantum Mechanics and obtain all of his wacky results.

In summary, Mills got a hold of some undergraduate quantum mechanics books and rederived everything assuming that the radial part of the equation is continuous and not quantized. His results are BS

This resonates with what somebody else wrote about Mills' theory.

I have examined Mills's work, as posted on the BLP web site, in some detail. Since I haven't been to BLP I can't claim any knowledge of what's going on in his labs. However, I can say with total confidence that the theoretical aspects of Mills's work are utter rubbish. The "theory" of hydrinos is completely full of mathematical mistakes, from start to finish. As a work of theoretical physics, it's totally meaningless, and it's so badly flawed that there really is no way to "repair" it. For those of you who complain that the theory is often dismissed out of hand by professional scientists who do not give it due consideration, here's a bit of explanation for why the theory is so totally incorrect.

This is followed by a long point-by-point elaboration. Referring to published experimental results somebody else wrote:

Dear Eric:
I put another hour into blacklightpower.com. So far it seems that there are no papers in peer-reviewed journals on the website. The technical papers available seem to have no journal reference. The "papers" presented at ACS meetings are talks, not papers, and are not peer-reviewed. Technically, there is not much I can follow, but they say in the first "technical paper" that conversion of a hydrogen atom (whose existence as a free species is doubtful, but is on a metal surface apparently) to a hydride ion makes it smaller. The sizes on my big laboratory chart say the opposite. There was no obvious source of electron to make the negative hydride ion. A statement is made in the first technical "paper" that "Alkali nitrates are extraordinarily volatile, and can be distilled at 350-500 deg. C. This sounded wrong, so I looked up all the ones I could find in the CRC Handbook. Lithium nitrate decomposes at 600° C, sodium nitrate at 380°, potassium nitrate at 400° and cesium nitrate at over 400°. So two blunders were found, making the whole business suspect.

And here is the quoted abstract from the February 1996 NASA technical report
Document ID: 19960016952 N (96N22559) File Series: NASA Technical Reports Report Number: NASA-TM-107167 E-10118 NAS 1.15:107167
(NASA Lewis Research Center). Authors: Niedra, Janis M. et al.

Replication of the Apparent Excess Heat Effect in a Light Water-Potassium Carbonate-Nickel Electrolytic Cell

Replication of experiments claiming to demonstrate excess heat production in light water-Ni-K2CO3 electrolytic cells was found to produce an apparent excess heat of 11 W maximum, for 60 W electrical power into the cell. Power gains range from 1.06 to 1.68. The cell was operated at four different dc current levels plus one pulsed current run at 1 Hz, 10% duty cycle. The 28 liter cell used in these verification tests was on loan from a private corporation whose own tests with similar cells are documented to produce 50 W steady excess heat for a continuous period exceeding hundreds of days. The apparent excess heat can not be readily explained either in terms of nonlinearity of the cell's thermal conductance at a low temperature differential or by thermoelectric heat pumping. However, the present data do admit efficient recombination of dissolved hydrogen-oxygen as an ordinary explanation. Calorimetry methods and heat balance calculations for the verification tests are described. Considering the large magnitude of benefit if this effect is found to be a genuine new energy source, a more thorough investigation of evolved heat in the nickel-hydrogen system in both electrolytic and gaseous loading cells remains warranted.

90) My talk at the 10th International Cold Fusion Conference

Ludwik Kowalski (August 10, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

The 10th International Cold Fusion Conference (ICCF-10, Boston) begins in two weeks. It is time start describing it. I am a nominal coauthor of a speculative theoretical paper presentation. The real author is Engvild, Kjeld Christensen; he is from Risoe National Laboratory in Denmark. Knowing that I am going to the conference he asked me to submit the poster as a coauthor. It was one day before the deadline. My own presentation, also submitted as a poster, was turned into a 25 minute talk. Instead of repeating what is in the poster (voices from Phys-L about cold fusion) I decided to share personal reflections based on what I learned about cold fusion. The view of an outsider, I suppose, may of some interest to researchers.

[#1] A preliminary comment on irreproducibility
Physics teachers know that electrostatic demos are highly irreproducible.

This must have been frustrating before the surface effects of humidity were recognized.

[#2] Another preliminary comment
Suppose that four probes were deposited on our planet by creatures living somewhere else in the universe. Conditions on their planet are totally different from ours. The probes landed in the same spot but several days apart. The first showed a wind of 50 mi/hr blowing north, the second and the third showed no significant wind while the fourth showed a wind of 30 mi/hr blowing to the west. Should the investigators conclude that the idea of moving air, formulated after the first reading, is erroneous? Certainly not. They should keep experimenting.

[#3] Last preliminary observation
Cold fusion is highly controversial. **What should a confused physics teacher do?**
(a) Avoid the topic because authorities declared cold fusion to be non scientific 13 years ago?
(b) Risk his or her reputation and discuss the issues?
(c) Play it safe and support official pronouncements?
Those invited to look into **Galileo's telescope** were in a similar situation**.**

[#4] I am Ludwik Kowalski,
a physics teacher from Montclair State University, Upper Montclair, NJ, 07043

The synopsis of this talk is available on my web site devoted to cold fusion.
To see it click on item #90 at **http://csam.montclair.edu/~kowalski/cf/**

[#5] Why am I here?
(a) I am interested in cold fusion. (b) I want to meet active researchers. (c) Are cold fusion phenomena real or not? I want to know the truth. Finding the truth is very difficult for an outsider. Let me show you a letter from a student **-->**

[#6] A letter from a student:
Dear Mr. Kowalski,
Help! My name is Maggie Johnson and I am a sophomore at Saratoga High School. In my chemistry class, I am doing a project on Cold Fusion. I was looking on the Internet for web sites on Cold Fusion, and I came across links to your Cold Fusion items. I was wondering if you could give me some advice or information?. . .

[#7] How to answer such requests?

A year ago I would reply that cold fusion is pseudoscience. But I am no longer comfortable with this kind of reply.

[#8] Why am I not comfortable?
My first opinion about cold fusion was based on Huizenga's famous ERAB report. I knew the author personally and I respected him. His criticism of cold fusion was convincing because it was based on the **"straw man,"** that is, on the idea that cold fusion is a thermonuclear reaction between two colliding hydrogen ions. Did he create this straw man or was it done for him by the unfortunate name "cold fusion?" Was he aware that he was fighting a straw man? I do not know.

[#9] Old arguments.
Those who criticize cold fusion today, Park in the US and Kruglyakov in Russia, essentially repeat Huizenga's arguments. What was convincing in 1989 is no longer convincing today. (a) Why do they ignore generation of helium? (b) Why do they ignore more sophisticated calorimetry? (c) Why do they ignore unnatural isotopic ratios? (d) Why are they not here learning about such findings?

[#10] I am still questioning.
After becoming aware of the "straw man" aspect of critical arguments I started questioning my own position. I am still not convinced that cold fusion is real but I no longer say that it is voodoo science. My reply to Maggie was limited to giving her references: Mallowe and Beaudette. I kept reading and learning.

[#11] Sharing what I know.
I decided to share what I learned about CF with other teachers. I did this on my web site: , http://csam.montclair.edu/~kowalski/cf/ Feel free to explore my short essays and to share them with others.

[#12] Why am I still puzzled?
(a) I am not able to perform experiments in school. This is likely to be typical.
(b) How comes that hundreds of sophisticated research scientists, trying to convince skeptics, have not developed a 100% reliable demo in 13 years? This is very indicative; windows of opportunity did exist in several countries.

[#13] What kind of evidence would convince a teacher?
(a) Not **calorimetry** in an electrolytic cell, unless the excess heat is very large (both in absolute value and percentage wise). Only experts can interpret very small effects.
(b) **Induced radioactivity** measurable with a Geiger counter, or with a gamma rays spectrometer, or with CR39? Oh yes, we are ready to test for radioactivity.
(c) **Reduced radioactivity**? Not very convincing; how can one be sure that the effect is not due to redistribution of materials within a cell? It can also be due to a removal of a layer of filtering material. Only experts can answer such questions.
(d) **Isotopic abnormalities?** Oh yes! This would be very convincing if sophisticated equipment were available in our schools.

[#14] How do we become convinced?
(a) Students learn from teachers and textbooks.
(b) Teachers learn from textbooks and journals.
(c) Scientists learn by performing experiments in the areas of their expertise.
(d) Bureaucrats follow administrative directives.
Which of these methods convinced you that neutrons and protons are made from quarks and gluons? Most likely you accepted a published consensus reached by experts.

[#15] Strategy for success?
(a) Convince **science teachers** by offering a reliable demo. Even a 70% reproducible demo would be useful.
(b) Convince **experts** with abnormal isotopic ratios. Convince **experts** with excess heat and with generation of 'ashes.'
(c) Demonstrate to **general public** that your most active opponents use 'straw man tactics' and that they ignore recent findings.
(d) **Do not make unrealistic promises** to general public. Keep making your papers available over the Internet.

(e) Openly criticize voodoo science.
(f) Publicize unfair practices of editors, and other bureaucrats.

[#16] Deplorable practice
Cold fusion papers are often published in journals which also publish papers dealing with antigravity, hydrinos, quantum healing devices, practical energy from zero point fluctuations etc. etc. Your papers are mostly experimental, they are not based on speculative extrapolations or on wishful thinking. But a reader may be left with such impression. The idea of having an electronic journal devoted only to cold fusion topics is very good, IMHO.

[#17] A new appointed panel to investigate cold fusion?
Most teachers are waiting for a consensus on cold fusion. They would welcome an official evaluation of new cold fusion findings. NSF first, DOE later! In other words, the primary focus should be on scientific findings and not on possible practical benefits. The evaluation should not be rushed, as the ERAB report was in 1989.

[#18] Trying to publish
Two times I failed to publish an appeal for the second evaluation of the cold fusion field. It was something like this: Can a nuclear process be triggered by a chemical process? The answer, based on what we know about nuclear phenomena, is negative. On the other hand many experiments seem to indicate the opposite. These experiments were performed many years after the first evaluation of "cold fusion" was made by our Department of Energy. As a teacher I would very much appreciate a second evaluation of the field by a panel of competent investigators.

[#19] Rejections
But my calls for the evaluation of new cold fusion claims were defeated by journal editors, and by their referees. I am referring to my jornals: Physics Today and The Physics Teacher.

[#20] From the rejection letter:
"The first referee offered only brief comments: 'I don't think The Physics Teacher is the right journal for this paper. Most readers of this journal are in no position to judge these rather esoteric matters. Indeed, most teachers wouldn't know what the fuss is all about.' The second referee's comments are attached [see below]. In the light of the referees' comments and of our own careful reexamination of the manuscript, we believe that TPT readers would not be able to make sufficient use of the paper to warrant its publication."

[#21] The second referee wrote:
"I must recommend against publication of this paper in *The Physics Teacher*. Despite the claim of 'helping teachers,' the paper seems actually to be an attempt to have a serious journal endorse cold fusion as a research field to be taken seriously. The pages of *The Physics Teacher* are not the appropriate place to make such arguments. . . .
[#22] The second referee continues:
" ..... Even if there were some validity to the now 14 years' worth of attempts at cold fusion (I haven't heard of any), *TPT* is about the last place in the world for this to be published." **Why was this individual chosen to be a referee?** S/he is not aware of progress made since the discovery of CF was announced in 1989.

[#23] From the Editor of Physics Today:
"So far, I have a split decision on the possible publication of your letter. I expect soon to have a tie-breaking input from a third reviewer. I will let you know as soon as I have a firm decision. Thank you for your patience."

[#24] What is next?
Sending my letter to referees was seen as an indication of objectivity. But two days later I was informed that Physics Today will not publish my letter. I asked for the comments made by referees.

[#25] From the Editor of Physics Today
". ....Please let me explain. I know that scientists who submit articles to peer-reviewed scientific journals expect reviewers to give them a critique of their letters. Physics Today is not, in the strictest sense, a peer-reviewed scientific journal; it is, instead, a special-interest magazine for physicists. Generally, my reviewers are staff writers and editors (all physicists) who may give me little more than 'thumbs up' or 'thumbs down' on a letter. As a rule, we do not give out

the specific comments of the reviewers, because we consider them to be internal business.

[#26] Predicting reconciliation
In my opinion, reconciliation between cold fusion and mainstream science is possible. But can this be achieved by a loose collection of individuals working on separate experiments? Those who ridicule you rely on a bureaucratic structure. Try to bypass them.

[#27] Reason for optimism?
"The scientific process is self-corrective. This unique attribute sets science apart from most other activities. The scientific process may on some occasions move slowly, sometimes even along a circuitous path. The significant characteristic of the scientific method, however, is that in the end it can be relied upon to sort out the valid experimental results from background noise and error." Who wrote this? Your critic, John Huizenga.

[#28] From the 1989 ERAB report
"The Panel recommends against the establishment of special programs or research centers to develop cold fusion. However, there remain unresolved issues which may have interesting implications. The Panel is, therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system."

[29] What will the history verdict be?
(a) Sooner or later, perhaps in 50 years, the cold fusion puzzle will be resolved.
(Like the "puzzle of cybernetics," or the "puzzle of genetics," both in USSR.)

(b) There are only two possibilities: cold fusion phenomena are real or they are not real. But this will not be the end of the story. The social aspects of scientific progress should be addressed.

[#31] If confirmed
If the reality of cold fusion is confirmed then causes of its condemnation by the scientific establishment must be studied. How to make sure that **a bureaucratic barrier is never again used** to slow down research?

[#32] If not confirmed
On the other hand, if cold fusion is shown to be fictitious then the long-lasting self-delusion, involving hundreds of recognized scientists in several countries, must be explained. **How do we know that such self-delusion does not happen more often than we think?** In any case, Cold fusion has been a significant event in the history of science; it will not be forgotten. It will be like the opposition to Galileo, several centuries ago.

#[33] What is "an impossible phenomenon?"
(a) A phenomenon not accountable by our current conceptual model (theory).
(b) A phenomenon that does not exist in the real world (it is a product of imagination).
Do not confuse these two meanings in a debate.

[#34] Nobel laureates
J. Schwinger and E. Teller, Nobel laureates, are often mentioned in cold fusion debates. But I did not know about a very critical review of R. Park's "Voodoo Science" book by another laureate, B. Josephson at:
http://www.tcm.phy.cam.ac.uk/ ~bdj10/articles/park.html

Teachers debate cold fusion

http://blake.montclair.edu/cf/poster.html

Ludwik Kowalski
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

What follows is a collection of messages about cold fusion from teachers. The messages were posted on the Internet discussion list, Phys-L, or were sent to me in private. They illustrate a wide range of opinion. PHYS-L is a list dedicated to learning and teaching physics with 700 subscribers from over 35 countries, the majority of whom are physics educators. To search in the archive of messages posted on Phys-L go to:
http://lists.nau.edu/archives/phys-l.html

Teacher 1:

The topic of cold fusion is most interesting but I'm surprised that it is still a topic of current debate on this list-server. **I recall that someone reported that cold fusion had been achieved a few years ago but no one has been able to reproduce the effect to this date. However, I thought that most scientists now agree that cold fusion can never be achieved.** Is there any new evidence to the contrary .....or is it like the alchemists who spent many fruitless decades trying to turn lead into gold?

Teacher 2:

I think there exists **new evidence for three things**:
1) Anomalous heat is now more reproducible, and not only via electrolytic loading. It has been observed in a deuterium gas discharge tube with a palladium cathode, and in a vessel containing palladium and hot deuterium gas at high pressure. But success depends on factors which were not known when cold fusion was announced.

2) Unusual nuclear processes (transmutations, emission of nuclear particles and electromagnetic radiation) accompany generation of excess heat. This happens in electrolytic cells, in gas discharge tubes and in high pressure vessels.

3) These puzzling processes do not resemble familiar thermonuclear fusion taking place in very high temperature plasma. The ratio of tritons over neutrons, for example, is highly skewed (by many orders of magnitude) in favor of charged particles. Another dramatic difference is that the reported production of 4He is not associated with the emission of 23.8 MeV photons; the released energy appears as heat.

Most of us are not able to verify these findings. That is why I think that i**t would be desirable if a new panel of experts** (physicists, chemists and material scientists) were created by our scientific establishment to evaluate the validity of recent findings and claims. I do not want to be like those who refused to look at what Galileo was showing because, according to Aristotle, such things were not possible.

Teacher 3:

The whole atmosphere around CF has been filled with **poisonous material**, some valid and some emotional. One must be very careful, on entry into such an atmosphere, to be protected by a useful theoretical proposal or at least a plausible explanation that can be subjected to experimental tests. **On the basic level there are two obvious questions:(1) How could hydrogen atoms fuse at such a low temperature? (2) If they do fuse,** how is the energy released (if not in gamma rays, then how) i.e. what reaction occurred?

If one has no proposed answer or proposed experiment to get an answer, then one is **in a state of massive weakness.** Your message seems to be that there is new evidence for an interesting mystery, and the early workers were not fairly treated. **The author of such a message will be classified as an apologist or defender, no matter how he qualifies such words.** If, however, he has a plausible proposal, it could possibly be different. I infer that the major skepticism in the mainstream nuclear science community stems from the silence on the basic two questions above. Such skepticism seems to me to be justified until something reasonable is proposed or, better yet, demonstrated. Until then, essentially all responses will be "impurities or errors".

Teacher 4:

First of all, just because someone says 'a new result is only accepted if there is at least a plausibility argument advanced to support it' doesn't make it so. **You don't have to look any further back than the announcement of high-Tc superconductors to see that such is not the case.**

Teacher 5:

When **challenging the "laws" of physics** there's a right way and a wrong way to go about it. (The same applies to any other activity.)

A1) The rules need changing, and the scientific community handles it well.
A2) The rules don't need changing, and it is handled well. Example: The null results of Eötvös.
B1) The rules need changing, and it is handled poorly.
B2) The rules don't need changing, and it is handled poorly. Examples: N-rays, cold fusion.

And there is a fifth class, where the scientific community responds scientifically but fails to bring the broader society along. Examples: copper bracelet therapy, magnetic bracelet therapy, homeopathic medicines. The task of challenging established ideas is not assigned only to giants like Michelson and Rumford and Rutherford, but also to every worker-bee in the scientific community. To summarize:

-- Primarily we should discuss the right way to challenge the established rules. And the necessity for doing so.
-- Secondarily we should discuss N-rays, cold fusion, homeopathy, etc. as counterexamples, as perversions. We shouldn't call them "positive".

Teacher 6:

The skepticism about "cold fusion" arises not because of any "conspiracy" on the part of "orthodox" science, but rather because literally **hundreds of competent scientists have attempted to reproduce the effect without success.** The nuclear reactions associated with fusion are well understood, and have well known signatures (reaction products such as neutrons and gamma rays). These have been looked for with the most sensitive of detectors, and have not been found.

Teacher 7:

I believe that it is nigh-impossible to change people's opinions regarding "Cold Fusion," so I usually am not tempted to dive in and argue about it. When any reversal of opinion requires the losing of face, then reversals of opinion cannot occur in public. Therefore why even try? If "CF" is eventually shown to be valid, then everyone will leap on the bandwagon, but there will be no detailed investigations of the ones who spent years ridiculing the topic. "Who, me? I was always a supporter!"

Teacher 8:

I enter this discussion with great fear, but I can't help getting this out of my system.
(1) Can we agree that there can be a small amount of **muon induced fusion** in a tabletop experiment, but not enough to make significant temperature changes?
(2) Can we agree that the other types of cold fusion that are being discussed **require us to violate Coulomb's Law and therefore are unlikely to occur?**

Teacher 9:

If the CF phenomenon is genuine, then it means that the staggering amounts of money put into Tokamak-style fusion might have been wasted. It means that hundreds of people devoted their careers to a technology which might prove of little worth should electrochemical-fusion result in efficient reactors. Obviously the pressures on such people would be tremendous.

Teacher 10:

In my reading of CF literature, **I've not encountered any "conspiracy theory" stuff.** In the "perpetual motion" and "antigravity" crackpot fields **the situation is far different.**

Teacher 11:

One reviewer wrote: “Professor Park does more than debunk, he crucifies... You'll never again waste time or your money on astrologers, quantum healers, spoon benders homeopaths, perpetual motion merchants, or alien-abduction fantasists.” But isn't "cold fusion" different from the above? I suspect that Fleischmann and Pons might become Nobel laureates.

Teacher 12:

What makes the CF area different from voodoo science?

1) A large number (several hundred) of cooperating scientists in about 10 countries are involved.
2) Two Nobel laureates (Teller and Schwinger) were theorizing about AE at one time.
3) Nearly all of the AE researchers have doctorates; many of them are (or were) associated with highly prestigious laboratories and universities.
4) These researchers organize one international conference each year and make results of their findings known to all who are interested.
5) Their methodology of validation is not different from that practiced by so-called "mainstream" scientists.They experiment, they hypothesize, they change their minds, they publish.
6) They are not secretive; they want to be heard and be criticized scientifically.
7) They want to have access (as authors) to all mainstream journals in order to benefit from the peer-review process.
8) They want their proposals to be considered by NSF, DOE and other granting agencies.
9) They are highly unhappy about the "blacklisting” of the entire field triggered by mistakes of those who tried to exploit the prematurely announced 1989 discovery.

Is it not obvious that claims made by “astrologers, quantum healers, homeopaths, spoon benders, perpetual motion merchants, or alien-abduction fantasists” **are completely different from those made by AE scientists?**

Teacher 13:

In science it's wrong to first adopt a viewpoint and then to use the selection of evidence in order to support that viewpoint. **Politicians do it. The legal system is based on it.** Science is totally different: a bend-over-backwards search for the truth rather than a defense of a an existing position during a debate. If one claims to be scientific, yet also adopts a position not based on evidence, then that is pseudoscience.

Teacher 14:

The cold fusion area is not voodoo science. But the phenomenon of pseudoscience is very real and society should be protected from those who exploit ignorance in order to benefit from unscientific claims. Selling healing bracelets is one example of this; the therapeutic effect of such gadgets, as far as I know, has not been validated. How can society be protected from con artists without confusing charlatans with honest scientists addressing non-conventional topics? This is a difficult issue.

Teacher 15:

I see CF as classic pathological science, as described by Langmuir. I cannot say for certain that CF isn't real. I suspect nobody can. But I would guess, based on the number of the characteristics of pathological science it has exhibited, the odds against it are pretty long.

Teacher 16:

It's not hard to destroy your career as a scientist. Simply take UFO sightings/evidence seriously and devote major time to investigating them. Or dedicate yourself to researching parapsychology. Pick any one of a number of "taboo" subjects such as Cold Fusion to study, and the greater scientific community will excommunicate you by closing off funding and the channels for publication.

Teacher 17:

It is very difficult to find a word to describe what it is that motivates the honorable person in his or her search for scientific truth. It is not exactly curiosity, which can be much more easily satisfied in the library. Feynman refers to the thrill of being the sole possessor of a secret of the universe for a few moments and, subsequently, revealing that secret to the world. There must be something involved in this feeling that comes from the ego, but that is not to say that the feeling should be disparaged.

Teacher 18:

The cold fusion situation in the USA can be characterized as a conflict between a group of scientists and the government (represented by DOE and NSF). This reminds me of two other conflicts of that nature; both in the former USSR. Soviet geneticists and Soviet cyberneticists were “excommunicated” on ideological basis rather than on the basis of scientific argumentation. These fields, labeled as “reactionary science,” were later rehabilitated. (But many “voodoo scientists” died in prisons and concentration camps before being rescued.)

Teacher 19:

What might skeptics say about recent cold fusion data?

1) Muzino and others in Japan are liars, like Karabut and others in Russia, like Bressani and others in Italy, like Lonchampt and others in France, like Bockris and others in the US. The data are fraudulent.

2) These people only pretend to be scientists. Their Ph.D. diplomas were counterfeit; their professorships at famous universities were bought; the books and hundreds of articles they published were produced by somebody else. They are members of an international “mutual support society.”

3) We already know everything about nuclear phenomena; facts which disagree with existing theories are not acceptable. Absence of commensurate amounts of neutrons and protons is a sufficient reason to ignore claims about unusual nuclear processes.

4) Cold fusion researchers were often wrong in 1989. Therefore what they are finding now must also be wrong. They should never be forgiven for announcing a discovery via a press release, or for claiming that excess heat experiments are very simple.

5) Claims made under the banner of cold fusion were not described in articles published in leading journals. Therefore they cannot be accepted. The editors of these journals refuse to publish cold fusion articles; they know better what is right and what is wrong.

6) Neither the Department of Energy nor the National Science Fundation supports research in the area of cold fusion. Therefore such research is not worth taking seriously.

7) Practical applications of cold fusion have not been demonstrated; therefore the underlying phenomena cannot be real.

8) We know nothing about recent cold fusion findings; therefore they must not be correct. The entire field was declared pseudoscientific in 1989 by a panel of experts. The opinion of experts must be respected; it can not be challenged by new findings.

9) Experiments should be 100% reproducible before they can be accepted.

Only the last reservation is sensible. Lack of reproducibility is a clear indication that some important parameters are still not under control by experimentalists, and that conclusions are tentative.

Teacher 24: (about anti-relativists):

The most basic problem with the "anti-relativists" is their intellectual dishonesty -- the refusal to think and recognize their errors no matter how many times, or in how many ways, such errors are clearly identified by those who actually understand. This sort of epistemological/psychological aberration is not anything new to relativity. In a 1922 letter to Max Born, Einstein incidentally mentions a "monumental blunder" he made "some time ago (my experiment on the emission of light with positive rays)." In his commentary on this letter, in the book "The Born-Einstein Letters," _Macmillan_, 1971, Born first mentions the "anti-relativists" who fail to learn from their mistakes as Einstein did. In one paragraph, Born notes:

"Finally, there are the pure cranks, outsiders who can point to no positive scientific achievements themselves but who believe that they have found defects in some new doctrine such as Einstein's theory of relativity. One would think there would be fewer of these as time goes on. But this is not so. Over the years a large number of first-class physicists and mathematicians have thoroughly investigated the theory of relativity and none has found fault with it. It is hard, therefore, today to take seriously anyone who believes he has discovered a mistake. **I have frequently taken the trouble to uncover the errors in papers written by cranks of this type, but never in all my experience has any of them admitted that he had made a mistake, as Einstein did."** Born's comments were written a long time ago, but his words remain true today. There will always be a small but hard-core group of intellectually dishonest "anti-relativists" who neither

A preconference C.F. workshop (8/24/03)

Workshop Objective:
This workshop is intended to provide an introduction to the field [of cold fusion] for persons interested in gaining a basic background in the science and technology aspects. Both theoretical and experimental topics will be covered for deuterium and proton based reactions.

1) **Introduction and course objectives**,
George Miley (15 min)
2) **Introduction to LENR,**
Ed Storms (45 min)
3) **Review** of experimental measurements involving DD reactions
Mike McKubre (1 hour).
4) **Review** of experimental measurements involving Transmutation Reactions
John Dash (1 hour)
5) **Working Lunch** Discussion session
led by George Miley (1 hour).
6) **Theoretical background for D reactions,**
Peter Hagelstein (1 hour)
7) **Theoretical background for Transmutation Reactions,**
Akito Takahashi (1 hour).
8) **Diagnostics for measurements** (Calorimetry, He4, Transmutation products/isotopes, Radiation emission, Metallurgical analysis)
George Miley, Mike McKubre, Ed Storms and John Dash (1 hour).
9) **Summary and discussion,**
Panel, G. Miley, chair and lecturers. (30 min)

93) Cases from Russia

Ludwik Kowalski (August 11, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

The situation in Russia, as described by Kruglyakov, can be found in the unit #86 of my list. This units focuses on selected fragments from his 2001 Russian book, "The Highwaymen of Science." On page 93 one reads that a claim for the "excess heat" was made in Russia in 1959, long before cold fusion was discovered. Several engineers from a Soviet factory, "Santechnika" [which translates into medical technology] announced a device constantly generating more heat than the amount of electric energy received. Scientists dismissed the claim but a poetess, Marietta Shaginian, came to the defense of inventors. She wrote; "**don't these scientists realize the importance of the discovery; it is a technological revolution!**" Her defense was widely publicized and created great excitement in the entire country. Finally Kapitsa, and other important scientists, had to be involved. "Fortunately, it was not difficult to find an error: an increase of temperature in the surrounding water had been ignored."

******

Another claim goes back to 1970s and the pseudoscientist is A. Cherniecki; in his case the rate of heat generated was several times larger than the rate of electric energy supply. The inventor believed that physical vacuum was supplying excess energy to his system. **"Many supporting articles, appearing in the press, were presenting only one side of the story. Three years later, however, it became known that the inventor, using various pretexts, did not allow experts to measure the input power."**

*****

After describing old claims Kruglyakov jumps to 1980's and focuses on Akimov, an active promoter of torsional fields which are said to propagate much faster than light, which can cary information, and which can kill. Kruglyakov reprints his letter to the editor of a widely read Russian Newspaper (RN). That letter exposes con artistry of Akimov in the former Soviet Union and in new Russia. It also criticizes harmful policy of the government newspaper to support pseudoscience. I could not stop thinking about similarities between E. Kruglyakov in Russia and R. Park in the USA. Why do these two physicists place cold fusion in the same boat as torsional radiation and other speculative (as opposed to experimental) claims? Don't they see obvious differences between situations in the field of cold fusion (see item #18) and situations in real pseudoscience areas (see items 56 and 57)? Significant differences between situations in two countries, however, did not escape my attention.

Instead of focusing on Kruglyakov's letter to the editor, entitled "On the other side of science," let me show the reply produced by the science editor of R.N. Valentinov. The reply, entitled "On that side of science," appeared on May 19, 1998. It illustrates position of a science editor who covers his support for sensationalism by pretending to be open-minded. Valentinov wrote:

[Kruglyakov] **"often accuses those who give money to Akimov -- the Science and Technology Commission, the Ministry of Defense and the FSB [the successor of KGB].....I suppose that defense specialists in charge of**

evaluations of Akimov's projects, and generals handling finical aspects of his work, will answer for themselves, if they decide to raise the curtain of secrecy a little. Kruglyakov accuses them to be scientifically and technically illiterate. His main target, however is not the army, it is the press. He asks: 'why are pseudoscientific projects, costing a lot of money, are advertised, rather then criticized, by popular press?' That money should be used to support research in mainstream science. "

If my memory can be trusted, the hypothesis that every rotating object, including elementary particles, is surrounded by the torsion field was suggested in 1902. But the field is so small that they can not be detected by the existing instruments. . . And then [in 1980's], Shipov and Akimov, asked: 'is it true that these fields cannot be measured?' That resulted in a scandalous accusation." Akimov is not the only one working in this field [names of researchers are provided]". Kruglyakov claims that journalists, informing society about work of pseudoscientists," are hurting real science.

"But how do journalists, reporting what they hear from researchers, can interfere with progress of science? . . . Was it us, journalists, who were responsible for wild accusations of our brilliant geneticist, Vavilov? Did we cooperate with those who killed the genius in the Vladimir prison? Are we responsible for the persecution of the cybernetician, Glushkov? That persecution delayed our scientific progress by decades. No, this was done by their scientific colleagues who 'paved the way for real science.' Consider N.A. Kozyrev, who found the new way to investigate time. . . . Was it us, journalists, who sent him to Stalin's camps for ten years? . . . No, all this was done by his colleagues, often academicians [Kruglyakov is an academician]." Kozyrev was later recognized for his discoveries, but "mental inertia" of scientists was responsible for attempts to keep this fact unknown.

"I am well familiar with this affair. I remember how academician Krat, the director of Pulkowski observatory, was trying to prevent me, physically, from interviewing Kozyrev in his office. Then he threatened me with consequences along the party line, in case I dare to publish the interview. But I did publish it and was nearly expelled from the party, and from work. Fortunately some vigilant journalists supported me from pages of official party newspapers. . . .

Explaining his own 'path to truth,' Kruglyakov refers to specialized journals where any submitted paper is independently evaluated by two or three experts and by a collective of editors who are recognized scientists. This process is supposed to designed to eliminate erroneous publications. And it often does this. But it is not uncommon that a work declared to be 'erroneous' turns out to be highly innovative. Academician Kruglyakov, I suppose, would like scientific publications in newspapers to undergo the scrutiny of experts. This implies censorship. Our report on the work of Akimov would never be published under such system. The same would also happen to all publications challenging somebody's obsolete claims, questioning somebody's competence or not convenient for other reasons."

******

Kruglyakov book contains comments on Valentinov's reply. Ridiculous nature of the stuff published in RN is illustrated by the following quotation from a published article:

"Loud cursing over a plant was like [an X ray] dose of 40 thousand roentgens. It resulted in the braking of the DNA chains, in the decay of chromosomes and in the scattering of genes. ..... Grains of wheat, after receiving a dose of cursing equivalent to 10 thousand roentgens, developed normally after being blessed."

This reminds me of "pet stones" that were advertised in the US, about two decades ago. The author's main point is that RN, is more interested in publicity than scientific integrity, that its scientific editor is a hypocrite and that promotion of ignorance harms national interest. Later in the book Kruglyakov writes: "Valentinov claims that RN journalists report what they hear from scientists. 'We trust scientists with advanced degrees,.....they [not us, journalists] are responsible for purity of science.' Beautiful words. But pages of RN have not been reporting science for a long time; only mysticism and devil worship. Your words, Mr. Valentinov, about confidence in people with scientific degrees do not match your

stubbornness in glorifying accomplishment of scientifically illiterate people."

******

Two academicians, E. Alexandrov and V. Ginzburg supported Kruglyakov but their letter to the editor of RN was not printed. That letter is reprinted in the book. The academicians wrote that "the freedom of opinion in exact sciences is poorly understood by some people. According to Valentinov, a physicist is free to either believe or not to believe in the theory of relativity. ..... **One must recognize that the unlimited freedom of choice does not exist because the laws of nature are objective. They do not depend on preferences of scientists. Differences of opinion can only exist at the level of hypothesizing. Once confirmed, a hypothesis becomes reality and freedom of opinion is no longer allowed. Conflicting points of view, however, can be encountered because scientists are human; they can be either right or wrong.**"

******

On page 177 Kruglyakov describes a tragic transformation of a gifted astrophysicist , N. Kozyrev [mentioned above by Valentinov], into a pseudoscientist. "**Before the war that scientists worked in Leningrad. In 1938 he was arrested and sent to a prison. According to witnesses, he noticed that after standing on the icy floor for a long time the feeling of coldness was replaced by the feeling of some warmth. Kozyrev speculated that time turns into energy. Then he started applying this idea to stars -- that might be the source of their energy. He could not possibly be familiar with the idea of nuclear origin of stellar energy. The hypothesis formulated in the prison was further developed after his return. It was a sad story. Those who knew him as a gifted physicist helped Kozyrev to defend a doctoral dissertation; he was the discoverer of lunar volcanism. But at the same time he was engaged in strange experiments. I know that his conclusions were not confirmed by two appointed teams of scientists. Kozyrev was a man broken by the depressive political system. Without being arrested he would probably have a brilliant scientific career. His bizarre ideas are now promoted by very strange people."**

******

Those accused of being pseudoscientists in Russia often compare the accusers with those who, in Stalin's times, persecuted geneticists and cyberneticists. These people were also accused to be pseudoscientists; they were often arrested and sent to concentration camps. This issue is addressed in several places. On page 14, after quoting another academician, Kruglyakov writes: **"Let me remind you that the persecution [of Soviet biologists] was not initiated by scientific institutions. It is true, however, that some scientists did participate. Unfortunately scoundrels can be found everywhere; only the bravest were able to oppose terror openly. It is very different now; today everybody is free to defend his point of view. ..... Let me also remind you [page 186] another detail [page 186] from our horrible past. Physicists often helped persecuted geneticists. Igor Kurchatov, for example, had a large department of biology in his institute [working on the atomic bomb project]."**

On page 199 Kruglyakov writes: **"Do you remember destruction of genetics and cybernetics? ..... That destruction was organized in the Propaganda Department of the Central Committee of Communist Party. Don't you know that physicists were saving geneticists when they could? Let me tell you that only a miracle saved physics from a similar destruction. I had a conversation with I. Golovin, the deputy director of Kurchatov's Institute. He said that one day Beria [the secret police chief] suggested to Kurchatov that idealistic physics, such as quantum mechanics and theory of relativity, should perhaps be purged. Igor Vasilevich immediately replied that the atomic bomb design is based on these two theories. The purging is not desirable because the country needs the bomb. Beria informed Stalin about this conversation. This resulted in the cancellation of a session whose purpose was to discuss an attack on physics."** Stephen Speicher, from Phys-L, reminded us a story from George Gamov's autobiography. In that book ("My World Line," The Viking Press, 1970) Gamov describes his own encounter (in 1931)

with those who believed that teaching relativity and quantum physics is not good for Soviet ideology.

94) Browsing the Internet

Ludwik Kowalski (August 13, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

1) **The web site at:**

http://dmoz.org/Science/Physics/Nuclear/Fusion/Cold_Fusion/

contains links to many sources for reading about cold fusion; they even have a link to my own web site on blake. The link to Scientific American Frontiers yielded three interesting articles, very critical of cold fusion. Like Huizenga, the authors are fighting the straw man. But this is likely to be typical among mainstream scientists. These articles were written in 1997.

******

2) **Matti Pitkänen,** a theoretical physicist from Finland, at:

http://www.physics.helsinki.fi/~matpitka/coldf.html

has a short reviews the entire cold fusion field followed by a theoretical interpretation. He lists questions that any theory of cold fusion should be able to answer:

a) Why cold fusion is not a bulk phenomenon?
b) Why cold fusion of the light nuclei seems to occur only above the
critical value x=about .85 of D concentration?
c) How fusing nuclei are able to effectively circumvent the Coulomb wall?
d) Why gamma rays are not produced, why the flux of high energy
neutrons is so low and why the production of ^{4}He dominates
(also some tritium is produced)?
e) How nuclear transmutations are possible?

Then he presents his theory; I am not able to follow it. He often refers to the TGD model. I never heard of it. Here is a sample of text which means nothing to me, probably because I am not familiar with the concepts involved.

Trojan horse mechanism provides a manner to avoid Coulomb wall: since the two D nuclei feed their electric fluxes to different spacetime sheets, they do not see the Coulomb wall. The description of the reaction looks roughly like follows. Two D nuclei collide. The incoming D feeds its em gauge flux to the atomic spacetime sheet labeled by prime k=k_{em}>=131 (the p-adic prime p is p=about 2^k, k prime or power of prime). The target D is attached to Pd lattice and feeds its electric gauge flux to k>= 137 non-atomic spacetime sheet so that there is no Coulomb wall. In the collision deuterons stick together and the transformation of di-deuteron to ^4He occurs instantaneously in the time scale of em interaction since strong interactions are involved. Also reactions involving strong decay to ^3H +H and ^3He+n are possible. The *same* diagram involves also the photon exchange interaction of D nucleus with the electrons at the atomic spacetime sheet and electrons or Cooper pairs at the non-atomic spacetime sheet: it could be this mechanism which makes possible the transfer of surplus energy to the electronic degrees of freedom instead of gamma rays.

Trojan horse mechanism might work also at the level of chemistry making possible to circumvent electronic Coulomb wall and might be an

essential characteristic of the catalytic action. In separate context I have dubbed this mechanism as 'Houdini effect'. Biosystems are full of extremely effective catalysts, which suggests that the claimed biofusion [biofusion1,biofusion2] is based also on Trojan horse mechanism (perhaps it is someday possible to produce metabolic energy by biofusion or perhaps Nature has already discovered the trick!)..... The model can be summarized conveniently using quantum field theoretical language. ^4He is described as a scalar particle having standard minimal coupling defined be the covariant derivative D_{mu}= partial_{mu} +ieA_{mu} plus magnetic moment coupling of form mu*B to photon field. Gradient coupling does not allow the decay of the virtual state since this would lead to a nonconservation of angular momentum. Since transition magnetic moment is of order e/M(He) (e denotes electromagnetic coupling), magnetic decay is supressed by a factor of order E^2/M^2(He), where E is the energy of the gamma ray.

What does it mean "to feed electric fluxes?" What is a "spacetime sheet?" What is the "em gauge flux?" What is "p-adic prime?" My lack of understanding does not mean that the explanation is not valid. Perhaps the explanations make sense to theoreticians. Perhaps I should look at references at the end of the document. I suspect that this will not be enough; somebody else must interpret the theory for me. In the absence of help I will remain suspicious. **P.S.** A quick look at

http://blues.helsinki.fi/~matpitka/cbook.html

makes me even more suspicious.

******

3) Rotational fields?

Kruglyakov wrote about claimed effects of axion (spin) fields. According to him such fields are likely to exist but they are too weak to be detected. Practical applications based on such fields are highly unrealistic. But fraudulent claims about devices generating rotational fields are common in Russia. Here is a translation of writing about rotational fields.

http://www.pmicro.kz/MISC/UFL/Almanach/AxionA.htm

There is even a suggestion that the field can be used a weapon to fight terrorism. Crazy? A trick to get money from the government?

******

4) An item on cold fusion from an encyclopedia:

The Columbia Encyclopedia, Sixth Edition. 2001. ". . . Research into the possibility of cold fusion, by Fleischmann and others, nonetheless continues, because of intriguing but inconclusive experimental results -- such as claims of the production of excess heat, helium, or tritium where heavy water reacts with metals -- and because of the desirability of producing relatively nonpolluting fusion energy in quantity at any temperature. Cold-fusion proponents believe that the fusion mechanism is different from that of "hot fusion" in that it encompasses some type of unusual nuclear reaction in the metal lattice involving deuterium and possibly other atoms. Several dozen models to explain the observed phenomena have been advanced, but none accounts for the full range of experimental observations."

******

5) Charle Platt has a description of some leading US cold fusion experimental scientists still active in the field. It can be seen at:

http://www.wired.com/wired/archive/6.11/coldfusion.html

a) **Edmund Storms** is not an antiestablishment pseudoscientist pursuing a crackpot theory. For 34 years he was part of the establishment himself, employed at Los Alamos on projects such as a nuclear motor for space vehicles. Subsequently he testified before a congressional subcommittee considering the future of fusion. He believes you don't need millions of degrees or billions of dollars to fuse atomic nuclei and yield energy. "You can stimulate nuclear reactions at room temperature," he says, in his genial, matter-of-fact style. "I am absolutely certain that the phenomenon is real. It is quite extraordinary, and if it can be developed, it will have profound effects on society."

b) **George Miley**, who received the Edward Teller medal for innovative research in hot fusion and has edited *Fusion Technology* magazine for the American Nuclear Society for more than 15 years: "There's very strong evidence that low-energy nuclear reactions do occur. Numerous experiments have shown definitive results - as do my own."

c) **John Bockris**, formerly a distinguished professor in physical chemistry at Texas A&M University and a cofounder of the International Society for Electrochemistry: "Nuclear reactions can occur without high temperatures. Low-energy nuclear transformations can - and do - exist."

d) **Michael McKubre**, director of the Energy Research Center at SRI International: "I am absolutely certain there is unexplained heat, and the most likely explanation is that its origin is nuclear."

Credentials of **Martin Fleischmann** have already been described in my unit #4. Work of several scientists from the US Navy labs are described in my unit #51.

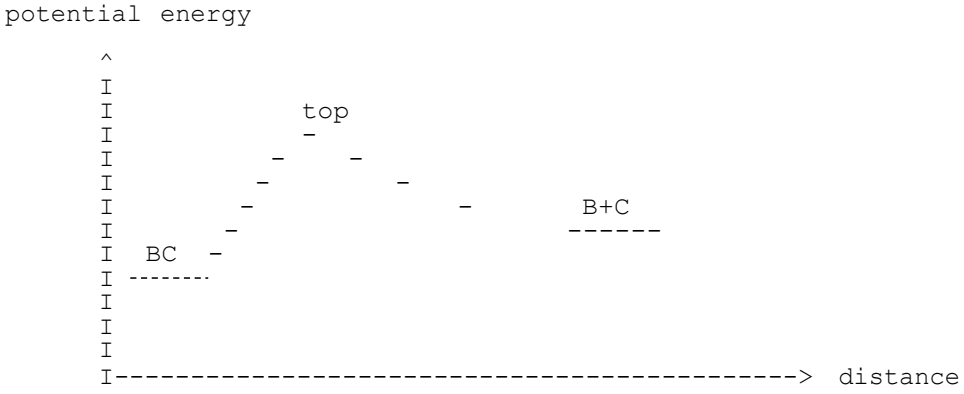
95) A catalytic model?

Ludwik Kowalski (August 13, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Catalysts are atoms or molecules affecting rates of reactions. These atoms or molecules may be independent, as in a gas, or be parts of structures, as in solids. In what follows no distinction is made between single atoms and groups of atoms. The term particle will refer to both a single atom or a group of atoms.

To simplify, let me assume that a catalyst is a gas A mixed with two reacting gases, B and C. In the absence of gas A one can imagine a reaction B+C --> BC. The number of B and C particles decreases in time while the number of BC particles increases. But at what rate does this happen? The answer depends on initial and final energies. If the energy of BC is higher than the energy of B+C then the reaction is called endothermic; such reaction will not take place spontaneously, even when a catalyst is present. The reaction rate is zero, unless energy is supplied.

On the other hand, if the energy of BC is lower than the energy of B+C then the reaction is exothermic and it can occur spontaneously. But the rate of an exothermic reaction depends not only on initial and final energies; it also depends on how potential energy changes with the distance between reacting particles. A typical situation is schematically represented below.



Note that although the potential energy of B+C is higher than that of BC it increases when the particles approach each other. We say that a potential barrier exists between the initial state (B+C) and the final state (BC). The height of the barrier (between the top and the B+C in the above figure) is called the activation energy. In general, the rate of an exothermic reaction depends on the activation energy; the rate is slow when the activation energy is high, and vice versa. Explosive reactions have very low activation energies. The role of a catalyst is to provide a path along which the barrier is lower. How can this happen?

In the presence of catalyst A our idealized reaction can proceed in steps, such as:

A+B --> AB followed by AB+C --> A+BC

Note that A does participate in the reaction; it disappears in step one and it reappears in step two. The net result is consumption of B and C, accumulation of BC, and a constant number of A particles. The rate of A+B-->BC, in the presence of a catalyst A, may increase when the activation energies in step one and two are lower than for the single step reaction (without a catalyst)..

What does all this have to do with cold fusion? I had to refresh my understanding of catalytic reactions after I noticed the word catalyst in several cold fusion papers. It is common knowledge that two D^+ ions repel each other electrically. But they attract each other strongly when the distance is very small. A cold fusion reaction, $D^+ + D^+ \rightarrow He^{++}$, was said (in 1989) to be theoretically impossible because its activation energy is of the order of one million of eV. That is why extremely high temperatures (tens of millions of K) are necessay to observe thermonuclear reactions in gases. But cold fusion seems to be happening on surfaces of some metals, such as Pd, Ti, Ni, etc.
Accordin to Storms, certain spots on such surfaces might act as catalysts facilitating fusion of deuterium ions.

The mechanisms of catalytic processes facilitating cold fusion are not clear. But one aspect is undeniable; the energy of BC (in this case He^{++}) is much lower than the energy B+C (in this case $D^+ + D^+$). The difference between B+C and BC, about 24 million eV, is much larger that the activation energy (about 1 million eV). One is tempted to think that the energy to “climb the hill” is somehow borrowed from the energy available in the “downhill fall.” This would be impossible in the independent single-step reactions (as in hot fusion) because released energy escapes in the form of 24 MeV photons. But in a system of millions of interacting atoms (a crystal catalyst) the borrowing may perhaps be possible. Instead of producing a 24 MeV photon, as in thermonuclear fusion, the energy released during each cold fusion event might go into the crystal and be subsequently used to promote another fusion. Conceptually this can be compared to a banking operation; borrowing on credit, paying back later and making profit. Many successful companies (exothermic events) must be involved to make this possible. Banks are social catalysts.

96) Another negative result.

Ludwik Kowalski (August 13, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

It is easy to generate a negative result; postulate something that nobody expects to happen and conduct an experiment showing that this does not happen. In unit 31 I already described a negative attempt to observe excess heat. Here I will describe a negative attempt to observe induced gamma radioactivity. But first a little start. About a week ago a colleague, Robert Dorner, told me about a modern "plasma metal cutting tool" he purchased. A highly controlled electric arc is established (in air) between the nozzle of the device and a metallic plate. The unit operates at 220 volts and the current of about 20A. An electric arc in air reminded me off the experiments of Hal Fox, from Salt Lake City, except that the medium is air instead of water. It also reminded be of Karabut's experiment, in Russia, except that the medium is air instead of deuterium gas. Is it possible that gamma radioactive isotopes are produced when metals are cut by the arc? Our conversation resulted in an experiment we performed this afternoon in Bob's garage. No induced gamma radioactivity was observed with a simple Geiger counter.

What follows is a description of what we did. The metal cutting tool used was "Plasma 30," from Harbor Freight (www.harborfreight.com). It has a nozzle from which hot compressed air is forced to flow along the electric field lines (between the wire in the nuzzle and the plate). The exposed areas melted and ejected metallic pieces were collected in a stainless steel dish. These pieces were then placed in front of a Geiger tube whose thin window was protected with two layers of a common office paper. Here are the results;

```
1) For our counter the center of the plateau curve was near 1300 volts.
   That voltage was used in all subsequent measurements.
2) Background before the experiments --> 226 counts in 5 minutes
3) Aluminum sample --> 232 counts in 5 minutes
4) Copper sample --> 245 counts in 5 minutes
5) Steel sample --> 233 counts in 5 minutes
6) Bismuth sample --> 220 counts in 5 minutes
6) Carbon brush sample -->  458 counts in 10 minutes
7) Background after the experiment --> 218 counts in 5 minutes
```

I know that it is silly to report such results. I am posting this description to show what one can do in a student-oriented project.

97) My Letter to the Editor of TPT.

Ludwik Kowalski (August 14, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

WHAT FOLLOWS WAS POSTED THIS MORNING ON THE PHYS-L SERVER. I AM ADDRESSING ABOUT 700 SUBSCRIBERS OF THAT DISCUSSION LIST. HOPEFULLY, SOME INTERESTING REPLIES WILL APPEAR ON THE LIST AND IN TPT.

My letter to the editor of The Physics Teacher was published in June of 2003. It is a comment on a student question about cold fusion. The editor, Karl Mamola, wrote to me: "This is the second summer that we have published letters on our website during the break in our publishing cycle, so that readers do not have to wait until September to read our Letters to the Editor." I would prefer the letter to be published on paper; it would then be seen by at least ten times more people. But the fact that the editor decided to publish my letter, considering the negative attitude of many, is significant.

Please, help to publicize the letter. The best way to do this is to reply with another letter. I do not think that The Physics Teacher is the right place to argue for or against the validity of various cold fusion claims. This should be done in scientific conferences and in peer reviewed papers. But TPT is a perfect place to let our establishment (AIP, NSF, DOE, Academy of Science, etc.) know that teachers and students would welcome a second formal evaluation of the field by appointed experts. Below is the content of my letter. The Internet reference is:

http://ojps.aip.org/journals/doc/PHTEAH-home/letters/jun2003.pdf

It is easy to submit a reply to a letter to the editor; e-mail your comments to Dr. Karl Mamola at: tpt@appstate.edu In doing this please indicate what you think about my appeal. Is a new evaluation of cold fusion claims desirable or should we stick to arguments found in the official 1989 evaluation? Also share examples of what students say or ask about cold fusion. Tell others how you personally deal with the subject.

ANSWERING QUESTIONS ON COLD FUSION

Let me begin by quoting a recent email message from a student.

"Dear Mr. Kowalski,
Help! My name is Maggie Johnson and I am a sophomore at Saratoga High School. In my chemistry class, I am doing a project on Cold Fusion. I was looking on the Internet for websites on Cold Fusion, and I came across links to your Cold Fusion items. I was wondering if you could give me some advice or information?"

How should a physics teacher answer questions about cold fusion? I am no longer comfortable saying that "cold fusion is voodoo-science." Can a nuclear reaction be triggered by a chemical process? The answer, based on what we know about nuclear phenomena, is negative. On the other hand many experiments seem to indicate the opposite. Some of these experiments have been described in refereed journals, others are available over the Internet. I am referring to papers published long after the first evaluation of "cold fusion" made in 1989 by a board of experts appointed by our Department of Energy. Their authoritative report (1)

was based on data available nine months after the initial announcement by Fleischmann and Pons. Many objections found in the report are still valid but some are at odds with new data. Accumulation of helium, for example, confirmed by several investigators, was not known when the report was released. How can progressive accumulation of helium be explained?

New findings about “cold fusion” phenomena are available to students over the Internet, for example, at www.lenr-canr.org . Many articles downloadable from that site were published by scientists associated with prestigious institutions. What should a physics teacher tell students about phenomena reported by these scientists? I have no clear answer to this question. That is why I think that a new authoritative evaluation of the “cold fusion” field, by a panel of competent investigators, is needed.

98) A cold fusion demo at MIT

Ludwik Kowalski (August 14, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

The web site of the ICCF-10 (10th International Conference on cold Fusion) has a brief description of a demonstration of excess heat from an electrolytic cell. Professor John Dash and his students (Portland State University) will perform the demo in an MIT laboratory. Here is how this event is described on the conference web site:

****

Demonstration

An excess heat experiment of John Dash is to be fielded in connection with ICCF10. This will be a technical demonstration to be done at MIT, in order to better inform the attendees about his work, and to respond to technical questions.

Technical description:

A control cell containing two platinum foil electrodes and an electrolyte containing sulfuric acid and light water is connected in series to an experimental cell containing a platinum foil anode, a palladium foil cathode, and an electrolyte containing sulfuric acid and heavy water. After passing current for several hours, the experimental cell is found to produce up to four watts of excess thermal power in comparison to the control cell. Excess heat is produced in about 75% of the experiments. Evidence of localized concentrations of silver is found on most of the palladium electrodes after electrolysis.

Three high school students and one graduate student will be on hand to discuss their results on these experiments.

Popular description:

Prof. John Dash and his students will show how they have investigated the excess heat effect associated with "cold fusion". An instrument to measure heat, called a calorimeter will be used to show how production of excess energy is measured. Using this apparatus, the students at Portland State University have generated this excess energy effect with frequent success. Perhaps unexpectedly, this energy is obtained from an electrolytic process involving only heavy water, palladium and platinum, with an acid used to conduct current through the solution.

A viewing of Dash's set up is planned for Monday night with the other events when the public is invited, in order to stimulate discussion.

Acknowledgment:

This research is performed in the low energy nuclear laboratory at Portland State University, Portland, OR, under the direction of Professor John Dash. It is funded by a grant from the Academy Of Applied Science and by a grant from the New York Community Trust. The New Energy Foundation provided transportation expenses to bring this demonstration team from Oregon.

****

Additional information about student's cold fusion experiments, with pictures of students and equipment, can be found at:

http://www.lenr-canr.org/Experiments.htm#HighSchoolStudents

In the middle of the document one finds this general description:

"High School Students Do Cold Fusion

Every summer, high school students work with Prof. John Dash, of Portland State University, in cold fusion experiments, as part of the Apprenticeships in Science and Engineering program, which allocates high school students to summer internships all over Oregon and Southern Washington. In 2003, Corissa Lee and Shelsea Pedersen participated. They will be seniors next semester. They were assisted by Ben Zimmerman, who was an apprentice in 2002, and who will be attending the University of Chicago this Fall. Zimmerman describes the 2003 program:

'Our experiment is very rudimentary electrolysis of palladium in a D20 and Sulfuric Acid electrolyte, running under modest current (from 3-4 amps) with a non-reactive identical control cell for comparison of heat flow. So far, we've analyzed temperature readings and found that the cells used so far produce on average .5 watts, and as high as .9 watts as excess. Also, we've analyzed the palladium cathodes of similar experiments and found anywhere from 2 to 20% of unaccounted for silver with an SEM after electrolysis from cathodes that produced excess heat.' "

At the bottom of the document one has a link to a poster summarizing a research project of Jon Warner, J. Dash, and S. Frantz. It is actually a poster, entitled, ELECTROLYSIS OF D_2O WITH TITANIUM CATHODES: ENHANCEMENT OF EXCESS HEAT AND FURTHER EVIDENCE OF POSSIBLE TRANSMUTATION. That poster was shown at the 9th International Conference on Cold Fision (China, 2002).

99) Shortening of a half-life?

Ludwik Kowalski (August 15, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

In item #98 I wrote about cold fusion experiments performed by students at Portland State University. Inspired by their teacher, John Dash, they studied generation of excess heat in an electrolytic cell. I will be able to see their demo at the 10th International Conference on Cold Fusion (ICCF-10). Will I be convinced that the excess heat is real? Or that it is not due to a chemical reaction of some kind? Too bad that my familiarity with electrochemistry is so limited. I would be in a better position criticize a nuclear effect demo because I am a nuclear physicist. Unfortunately, there will be no nuclear cold fusion demos at the conference, only papers describing various nuclear effects. John Dash's paper, for example, is entitled "effects of hydrogen loading by aqueous electrolysis on radioactivity of uranium." Is he going to say that the electrolytic loading has the same effect as loading it in a gas discharge tube? The gas discharge data have been published at the previous cold fusion conference (ICCF-9, China, 2002).

John's paper, presented in China, can be downloaded from the library at http://www.lenr-canr.org . Here is the abstract from that paper: "Uranium foils were attached to the cathode of a glow discharge apparatus. A plasma of either hydrogen or deuterium ions was used to bombard the uranium. The rates of alpha, beta, and gamma radiation emissions were significantly greater for the bombarded uranium than for the original material." For alpha particles, for example, the rate of decay, after the processing, was four times higher than before processing. Uranium foils were used as cathodes in a glow discharge tube (5 tor, 500 volts, 5 mA). The processing lasted about 500 hours.

How can a nuclear physicist accept such an allegation without actually performing an experiment? But the apparatus used was similar to that of Karabut, who also observed several unbelievable nuclear effects. The first step should be to formulate the so-called "null hypothesis," as in statistics, and to do everything possible to validate it. Failures to validate the null hypothesis can then be used as the basis for accepting, still tentatively, a highly unusual claim. I met John in Albuquerque last Fall and I read his China paper. Expressing my disbelief I said that I would be willing to spend several days in Portland, at my own expense, and participate in experiments. My offer was not accepted; I suspect this had something to do with a pending patent application, or with John's desire not to share potential rewards for a "revolutionary discovery." I can understand such motives. What would I do in John's situation?

1) Not being a nuclear physicist I would welcome the offer of somebody who is. The patent aspect could be solved by asking that person (Ludwik) to sign a legal document, as they do in national labs. Another precondition could have been an understanding that the person will not be a coauthor of a publication resulting from the study.

2) My first concern would be the possibility that the discharge apparatus, or the gas used, was radioactively contaminated in the past. I suppose that John has checked for the absence of contamination, for example, by placing control foils into the apparatus (at zero volts). Without such a test one might suspect that contamination was responsible for the observed effect. The radioactivity of natural uranium is weak.

3) My next concern would be the possibility that a thin layer of some covering material was removed during the processing. The removal of a "dead layer" from a thick uranium target could possibly lead to a higher alpha emission rate after processing. The same parasitic effect could possibly result from a change in the smoothness of the uranium foil. According to Figure 8, erosion of the surface of uranium did take place during the processing.

4) Instead of using a large area alpha probe (Ludlum 43-5) I would use a small Si detector connected to a multichannel analyzer. A significant shift toward higher energies, resulting from processing, could be a warning signal that a change

in the emission rate might be an artifact. I do not think that it was necessary to use a counter whose window area was about 100 times larger that the area of the alpha source. The signal to noise ratio would be more favorable for a smaller detector.

5) Here is my main question. Why is a change in the alpha decay rate much larger than changes in the beta or gamma decay rates? It seems to me that all three counting rate changes (alpha, beta and gamma) would be identical if uranium nuclei started to transform more rapidly. Why was this question not addressed in the paper? Will it be addressed in John's ICCF-10 paper?

100) Physics Today rejected my letter

Ludwik Kowalski (August 14, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

As I wrote yesterday (see item #97), my Letter to the Editor has been published by The Physics Teacher. My attempt to publish a Letter to the Editor of Physics Today, however, was not successful. Let me document this failure. Here is what I wrote:

****

To the Editor

The January 2003 issue of Physics Today had an interesting item entitled "New APS Ethics Guidelines Address Research, Misconduct and Professional Responsibilities." The author, Jim Dawson, summarized main points of the **new ethics guidelines** recently adopted by the American Physical Society (APS) panel on public affairs. I was particularly interested in this segment:

"You should hang on to your data, you should respond to inquiries from other scientists, and you should be responsible as a referee. . . The new guidelines, approved on 10 November, come in several parts. A policy statement on how to handle allegations of research misconduct defines misconduct as 'fabrication, falsification, or plagiarism in proposing, performing, or reviewing research, or in reporting research results. ..... ' Such behavior is termed an 'egregious departure from the expected norms of scientific conduct that can lead other scientists along fruitless paths.' It also 'diminishes the vital trust that scientists have in each other' and undermines public confidence in science. The statement goes on to say, 'It is imperative ..... that the institutions responsible for funding and performance of scientific research, as well as the relevant professional societies, take appropriate steps to discourage such conduct' ..... "

I welcome the new guidelines but I would like to examine them it in a slightly different context than emphasized in the article. How can a physics teacher make sense of "cold fusion?" Is there any evidence that this field, in terms of what has been done in the last ten years, is a "departure from the expected norms of scientific conduct" or that it "can lead other scientists along fruitless paths?" I think the 1989 ERAB report was correct in that no convincing evidence existed to support the premature claim of Fleischmann and Pons about a new source of useful energy.

But the situation has changed in the last ten years. Scientists conducting research in this area no longer claim that demonstrations of excess heat are easy (as initially announced) or that the underlying mechanism is simply a fusion of two nuclei, as in hot plasma. But they "hang on to data" indicating that something significant was discovered in 1989 and that it should be studied, as recommended in the ERAB report. I see no evidence that the data are "fabricated." Is it true that editors of many peer reviewed journals automatically reject manuscripts dealing with "cold fusion?" Is it true that "institutions responsible for the funding and performance of scientific research," such as DOE and NSF, automatically reject research proposals dealing with "cold fusion?" Is it true that young researchers avoid this field for fear of endangering their professional careers?

I have heard such allegations from several "cold fusion" scientists. They claim that the entire field has been blacklisted in the US. If this is true, then, in my opinion, the situation should be reviewed in light of new ethical guidelines. Those guilty of falsifications should be exposed as pseudo-scientists while those who made "honest errors" should be

criticized, as in any other field of science. And those whose claims are accepted as valid should be rewarded (in the form of published papers and financial support for research) as in any other area of science.

As a physics teacher I am confused by the situation. What should we tell students when they ask about the discovery of Fleischmann and Pons? Most teachers have no time and no means to validate claims made in the area of "cold fusion," and need guidance. An objective summary of what has been done in that field, in the last ten years, would help us to describe it correctly. The issue is not only scientific; it is a topic of general interest. Most educated people know about the "cold fusion episode" and opinions about it are divided. Some say it was "a fiasco" while others say it was an "important discovery." How should teachers address this topic in the context of "public affairs between science and society," or in the context of discussing "institutional support for new ideas and innovations?"

****

After waiting several months I sent an e-mail message asking about the status of my letter. On Thursday, June 12, 2003, I receive a reply from Marty Hanna, Letters Editor at Physics Today. He wrote: So far, I have a split decision on the possible publication of your letter. I expect soon to have a tie-breaking input from a third reviewer. I will let you know as soon as I have a firm decision. Thank you for your patience."

My immediate reply was brief. "Dear Dr. Hanna: Thanks for giving my Letter to the Editor a chance. In reading it again I see a typing error which may not be noticed. Please correct it before publishing. The ERAD acronym should be replaced by ERAB; it stands for the famous 1989 Energy Research Advisory Board. By the way, I hope that a similar board of experts will be appointed to examine new cold fusion data. My "confusion about cold fusion" is probably typical; many physicists need help to interpret information widely available in that field."

On Thursday, July 3 Dr. Hanna wrote " We have completed our review of your letter commenting on the APS ethics guidelines story in our January 2003 issue. Our decision, after some valuable discussion, is not to publish your letter. Thank you for writing and for your interest in Physics Today." Unhappy about this I wrote "I would very much appreciate if you could send me the reports of the referees evaluating my letter to the editor. I wish you nice holidays." The immediate reply was " Thank you for your inquiry. Please let me explain. I know that scientists who submit articles to peer-reviewed scientific journals expect reviewers to give them a critique of their letters. Physics Today is not, in the strictest sense, a peer-reviewed scientific journal; it is, instead, **a special-interest magazine** for physicists. Generally, my reviewers are staff writers and editors (all physicists) who may give me little more than 'thumbs up' or 'thumbs down' on a letter. As a rule, we do not give out the specific comments of the reviewers, because we consider them to be internal business. Thank you for your inquiry. I hope my explanation has helped.

The input from three qualified referees would be very useful to me. Whose "special-interest is being protected by not showing me what they had to say? I am a member of APS and I expected a better treatment from my journal. It is ironic that my letter was triggered by an article about ethical standards in science.

Let me remind you that the rejection of my cold fusion note, by TPT, has already been described in item #49. Even recognized experts encountered difficulties in trying to published cold fusion articles, as illustrated in items #33 and #9. This is not a healthy situation; here is how it was described by E. Storms: "Serious scientists rejected 'cold fusion' in the past for good reason. These reasons no longer apply. If science cannot correct a past rejection, then what good is the scientific method?" Physics Today should promote exchanges of information among recognized physicists from different disciplines. It is an ideal place to ask a question formulated in my letter. Why did Dr. Hanna reject the letter after one of the referees recommended it? Which special interest is he protecting by not publishing the letter? I am probably not the only physics teacher confused by the existing situation in the area of cold fusion. What is wrong with asking for another evaluation of that field by an appointed panel?

P.S.
After posting the above I realized that part of it is a repetition of what has aleady been shown in item #88. I am sorry for this.

101) Excess heat again

Ludwik Kowalski (August 15, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

I am reading the article the John Bockris published in Journal of New Energy (vol 4, no 2. 1999, p. 40). It explains how the so-called "excess heat" was measured by this famous electrochemist. I do not know why, in some places, Bockris confuses energy with potential; I am sure he knows the difference between these two concepts. He writes, for example, "this energy is represented by the electrochemical potential applied to the cell." In another place he writes that "I^2*R heat is included in E, the total potential applied to the cell." I would not use E for the difference potential and I would not confuse E with rate of using electric energy. Sloppy formulations tend to discredit a scientists. But I will ignore them.

Suppose that the difference of potential, E, is applied to a cell in which water is electrolyzed, and that the current is I. The input power is E*I but the heat generation rate is (E-1.54)*I because 1.54*I is the rate at which energy is used to produce bubbles of oxygen and hydrogen. The excess heat generation rate is a difference between the heating rate measured, P, and the (E-1.54)*I, provided no recombination of hydrogen and oxygen takes place inside the cell. In Figure 5, for example, the excess heat was zero during the first 60 hours, was slowly increasing up to 40 mW during the next 50 hours and remained constant (40 mW) in subsequent 50 hours. I am not impressed by 40 mW but I believed that it can be measured very accurately.

How do they measure heat generation rates, P.? The cell is surrounded by a constant temperature bath (plus or minus 0.1 degrees C). But the measured temperature inside the cell, after the equilibrium is reached, exceeds the temperature of the bath by dT. It turns out that a relation exists between the true heating rate, P, and dT. The relation is linear as long as dT is not larger than about 7 C. The coefficient of proportionality between P and dT, for example 0.8 W/C, is determined by calibrating the cell with ohmic resistors. Knowing the coefficient k one can always determine the true heating rate as P=k*dT. The excess heating rate, H, as indicated above, is given by:

$$H=k*dT-(E-1.54)*I$$

where H is watts, dT in C, E is in volts and I is in amperes. This approach, used by Fleischmann and Pons, was also employed by Bockris and his coworkers. Different calorimetric approaches were later developed by other scientists. The way in which H was measured by Karabut, for example, was described in unit #13.

The remaining part of the paper deals with evidence for nuclear effects: production of tritium, production of helium and transmutations. But that evidence is not very convincing. The paper has a lot interesting information on people, and on their motivation in early 1990s. But it offers no description of reproducible observations. Even suspected cases of fraud are mentioned.

Fleischmann, Jones and students

Ludwik Kowalski (August 29, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

The 10th International Conference on Cold Fusion (ICCF10) ended yesterday (8/29/2003). The next conference, ICCF1, will take place next year in Marseilles, France. The school year starts next Tuesday and I will have much less time to devote to cold fusion. This is probably my last CF item for at least a month or two. Let me share some details.

Both Martin Fleischmann and Steven Jones were present and gave interesting reports at the conference. I knew that Fleischmann is still active but current cold fusion work of Jones was new to me. As expected, Fleischmann's presentation was mostly about electrochemical details while Jones' presentation was about a recent experiment in which nuclear particles (emitted from deuterided metal foils) were detected by using traditional nuclear counters. We talked about his very convincing nuclear signature and he invited me to visit the lab and possibly work with him. Too bad this did not happen when I was desperately trying to be invited somewhere (it was a sabbatical year) to participate in a cold fusion experiment. I will certainly visit Jones' lab in January. He is also preoccupied with tritium in some volcanic gases.

Another thing I want to describe is a student demonstration of a cold fusion experiment. Three high school students and one graduate student, guided by professor John Dash, set up a demo for the conference participants. Two electrolytic cells were connected in series with a power supply delivering a constant current of 3.5 amperes. Cell #1, labeled "control," had two platinum electrodes and used an ordinary water electrolyte. Cell #2, labeled "sample," had a palladium cathode and a platinum anode. It used a heavy water electrolyte. The DOP on the control cell was 3.03 volts while the DOP on the sample cell was 2.80 volts. In other words the electric energy was delivered to cell #1 at the rate of 10.6 W while to cell #2 it was delivered at the rate of 9.8 W. The two cells were geometrically identical; they also had identical catalysts recombining gases (hydrogen and oxygen).

On that basis one would expect cell #2 to be warmer than cell #1 (10.6 W versus 9.8 W) . But the equilibrium temperatures measured did not confirm this expectation. The temperature of cell #1 turned out to be 89.1 C while the temperature of cell #2 was 89.8 C. The difference of temperature, 0.7 degree, could be interpreted as an indication that some kind of additional energy was converted into heat in cell #2. Quite an impressive demo for a summer project for three high school students at Oregon State University! I am not saying that the nuclear origin of excess heat has been demonstrated in this simple experiment. As far as I know it was the first student-conducted experiment trying to demonstrate the reality of cold fusion. Sensing an opportunity to immortalize a historical event I grabbed a camcorder and filmed everything. I also interviewed students and their guests.

It would be nice to edit the footage and produce a 30-minute film. Unfortunately I will be too busy to do this right now. Can somebody who has time and desire help me with this? If so please contact me in private; it can be a nice item for an AAPT conference presentation. John Dash gave me a signed permission to use the recorded footage. Fleischmann and Jones also gave me signed permissions to publish photos and footage recording their conference presentations. My own presentations at the conference (a poster and a 25-minute talk) were also filmed but are much less important in the context ot the ongoing cold fusion debate. I showed the "Letter to the Editor, " published in The Physics Teacher (June, 2003),

http://ojps.aip.org/journals/doc/PHTEAH-home/letters/jun2003.pdf.

and I asked questions about means of communication between the cold fusion community and other scientists. The

conference was a very important step in my attempts to form a definite opinion about reality of what has unfortunately named “cold fusion.” I knew several scientists by names; now I know them personally, more or less. Let me tell you that most of them are real scientists. The main critic of cold fusion, Robert Park (from AIP), was invited to the conference. But he did not come, presumably due to a timing conflict. He missed a great opportunity to learn about what is going on in several countries. He also missed an opportunity to argue about cold fusion with those who work in the field. This would be much more challenging then publishing “voodoo science” declarations. Robert Park worked on surface physics phenomena before becoming a spokesman for AIP. His absence deprived me of an opportunity to hear an open cold fusion debate between a knowledgeable opponent and knowledgeable proponents.

Post Scriptum:
A subscriber to Phys-L, an Internet discussion list for physics teachers, read and commented on the above description. Replying to his message I wrote:

“ . . . It would be foolish to use these data as an indication that something nuclear is going on. My emphasis was on the fact that a teacher, John Dash, was brave enough to give students a project based on a controversial subject. No attempts were made, as far as I know, to argue that excess heat can not possibly be attributed to chemical reactions, etc. The assumed ‘steady state’ situation can also be questioned. No calorimeter was used in the experiment to measure the amount of thermal energy.

The nature of the apparent excess of thermal energy should be discussed but not necessarily at the level at which students learn about differences between volts, watts and amperes. At a more advanced level I would ask students to calibrate the cell, that is to establish a relation (probably not linear) between the excess temperature and excess thermal power. The next questions would be:

```
a) how can the observed temperature difference of 0.7 degrees C be explained?
b) what else can we do with available tools?
c) what additional tools would help us?
d) etc. etc.
```

Personally I am very critical of calorimetric data when heating rates are very small; nuclear signatures reported at the conference are much more convincing. They show that something very unusual is taking place in some cold fusion experiments. But that is a different subject.”

104) Another case of new alchemy

Ludwik Kowalski (August 30, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

New version (with references + appendix) of this draft now exists as item #123 in this list. Read it instead of this item.

Is it possible that data presented by Japanese researchers were simply invented to deceive those who came to the conference? Yes, this is possible. But transmutations of heavy elements in "cold fusion" experiments have been reported by at least ten different teams of researchers. The authors are Ph.D. scientists and recognized authorities in their fields. An international conspiracy of some kind? Yes, this is also possible. But accusations of that kind must be supported by some kind of evidence. As far as I know, nobody accused top cold fusion researchers of fabricating data in order to deceive. By the way, I think that John Bokris, a highly distinguished electrochemist from Texas A&M, was the first to report on nuclear transmutations of trans-helium elements. This was ten years ago.

I am also working on item #124 (A more penetrating review of one of S. Jones' articles). A less penetrating review of his three articles presented at the 10th International Cold Fusion Conference has already been posted as item #113

105) New alchemy from Japan

Ludwik Kowalski (September 1, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Another conference participant, Dr. Talbot Chubb, was also impressed by Iwamura's findings (see my unit #104). I did not know that the research started several years ago and that the results were confirmed by a team from Osaka University. What follows is Chubb's description, as posted at the www.lenr-canr.org site.

"Nuclear reactions replicated at Osaka University

The ICCF10 international gathering of 'low energy nuclear reaction (LENR)' scientists has just been completed in Cambridge, Massachusetts. The results presented at this meeting seem destined to affect the course of solid state and nuclear science. Probably the most important of the results were those concerned with a unique form of nuclear transmutation reported a year ago by Iwamura *et al*. of Mitsubishi Heavy Industries. (Click here for their papers from ICCF-7, ICCF-9 and a link to their paper in the Japanese Journal of Applied Physics.) The Mitsubishi transmutations occur on a deuterided metal substrate. The transmutations convert carefully deposited surface cesium atoms into the rare earth praseodymium. These transmutation reactions have now been duplicated by Osaka University scientists. They have repeated the transmutations several times. The Osaka praseodymium product has been verified by neutron activation analysis (NAA) at the Japan Atomic Energy Institute.

Meanwhile, Mitsubishi Heavy Industries has continued to make progress. The Mitsubishi scientists have further confirmed the identification of the praseodymium product, using a number of independent diagnostic techniques. They have shown that the transmutation occurs both with chemically deposited and ion-implanted cesium atoms. Surface profiling studies have been carried out and have located where the reaction occurs by measured the depth distribution of cesium loss and praseodymium creation. The results show that the nuclear reaction is a surface or near surface reaction on the substrate metal. Precise chemical analyses of the bulk metal substrate have shown that the praseodymium nuclear product is much too plentiful to be due to impurity migration from the bulk.

In the Mitsubishi process a nuclearly active form of deuterium is created from a flowing stream of deuterium atoms inside a metal. The flowing stream is forced to encounter and overcome specially designed internal diffusion barriers. A new form of active deuterium is created during this inhibited diffusion process. The active deuterium is able to spread out and interact with the nuclei of target atoms despite the deuteron charge. The nuclear reactions are of a specific type. They are deuteron addition reactions in which 8 deuterons (or 2 alpha particles) are absorbed by a target nucleus. The cesium conversion reactions can be viewed as the inverse of alpha-particle radioactive decays, which were discovered and characterized by Becqueral, Curie, and Rutherford near the end of the 19th century. The cesium reaction has been called a 2-alpha addition reaction. The full range of addition reactions that can occur using nuclear active deuterium has yet to be determined. The Mitsubishi work identified both: (1) a reproducible method for creating the active deuterium, and (2) a clear diagnostic method that quantifies its presence.

The Osaka and Mitsubishi studies provide solid evidence that deuteron or alpha-addition nuclear reactions can be made to reproducibly occur on solid metal at a temperature below that of boiling water. The new results were reported by Iwamura of Mitsubishi Heavy Industries and Higashiyama of the Nuclear Engineering Department of Osaka University. The Osaka low energy nuclear work is lead by Akito Takahashi. The original Mitsubishi discoveries have been published in English in the internationally respected Japan Journal of Applied Physics (Iwamura et al., 2002), and are available on the web.

The new discoveries remind one of the beginnings of neutron-capture physics. In 1932 Chadwick discovered the neutron. His neutrons were produced by the impact of alpha particles on beryllium. Within a few years a large number of previously non-existing types of nuclei were synthesized by exposure of various target elements to neutron irradiation. During these neutron-absorption studies uranium fission was discovered and the new element plutonium was synthesized. By the end of 1942 the first controlled nuclear reactor was already in operation. A nuclear power plant was generating electricity in 1955.

It seems likely that the larger international community will build on the Japanese work. Further attempts to replicate the Mitsubishi protocol are in progress. Hubler at the U.S. Naval Research Lab announced plans for replication testing in consultation with the Mitsubishi scientists. It is to be hoped that the world community will quickly join in an effort to better understand the new active deuterium matter form, its reaction physics, and its usefulness in generating safe nuclear energy heat."

106) Why is Ramsey silent today?

Ludwik Kowalski (September 2, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Here is a fragment from a message received this morning from Kjeld Engvild. He is a scientist from Risoe National Laboratory in Denmark. Kjeld wrote: ". . . I have been following the CF discussions for many years now (mainly as a lurker) and I still don't know if (although I hope) the effect will turn out to be genuine. The field seems to have been stuck for some time, but the latest results from Mitsubishi may turn up something, although the results seem almost incredible, and certainly not explainable within the present theoretical framework. ..... "

Replying to the above, I wrote: "..... I was also very impressed by the results from Mitsubishi. I even wrote two items about this work on my cold fusion web site (#104 and #105). But like so many other cold fusion experiments, this one is far above what can be done by a typical physics teacher, even in a university. How come that so many highly qualified scientists (probably more that in the Manhattan project) could not offer a single "nuclear signature" experiment for people like me in 13 years? Even a 75%
reproducible demo would be convincing..... " Unless I have such demo I will remain neither a believer nor a denier of cold fusion. The only thing I am certain is that the field is ready for another formal evaluation.

Several speakers at the 10th International Conference on Cold Fusion, which I attended last week, also expressed the desire for a new evaluation. One of them, Michael Staker, said that several years ago Norman Ramsey, the Nobel prize laureate, expressed a similar wish (in a private conversation). This is very significant because Ramsey was one of those who signed the ERAB report. According to Eugene Mallowe, Ramsey was the author of that pair of report sentences: "**However, there remain unresolved issues which may have interesting implications. The Panel is, therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system.**" This was added to the report to persuade Ramsey not to resign from the panel headed by Huizenga. But what prevents Ramsey, who is a chemist, from publicly requesting a new evaluation of the cold fusion claims? His appeal, for example, in a letter to the editor of Physics Today, could not be ignored. I think that it would lead to a new national study of cold fusion.

Why am i optimistic that that the puzzle of cold fusion will eventually be solved? Because the "scientific process is self-corrective. This unique attribute sets science apart from most other activities. The scientific process may on some occasions move slowly, sometimes even along a circuitous path. The significant characteristic of the scientific method, however, is that in the end it can be relied upon to sort out the valid experimental results from background noise and error." Who wrote this? John Huizenga, the author of the highly negative ERAB report.

107) Biological manifestations of CF ?

Ludwik Kowalski (September 2, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Let me continue sharing what I learned at the 10th International Conference on Cold Fusion (Boston, August 2003). In his review of cold fusion Edmund Storms mentioned that some people reported transmutation of elements by bacteria. The classic book in this area is that of C. Louis Kervarn (ISBN 0-916508-47-1). The title is "Biological Transmutations." The book, costing $18,50, can be ordered by calling 1-800-867-7258 (from Happiness Press in Magalia, California). According to Kervarn (1901-1983) bacteria can speed up the decay of radioactive ^{203}Hg (whose half-life is 46 days). He refers to an experiment of L. Magos et al. in England.

In that experiment radioactive $^{202}HgCl_2$ was placed into the kidney of a rat. The radioactivity was measured with a Geiger counter. During the first 32 hours the decay curve was exponential as expected. But then the counts per minute started to go down with respect to the exponential curve. Sixteen hours later (at t=48 hrs) the counting rate was 50% lower that along the initial exponential curve. The experiment was performed at room temperature and evaporation of mercury was negligible. According to authors the first 32 hours correspond to the growth of bacterial colonies. Then bacteria (pseudomonas) start transforming radioactive mercury into something that is not radioactive.

How come that this experiment, performed in 1970s did not become famous? Famous for demonstrating alchemy or famous for reporting results which could not be confirmed by other scientists. After all the announcement of Magos et al. was as unexpected as the announcement of Fleischmann and Pons. Why didn't it trigger a debate? Does this support the idea that motivation of the cold fusion uproar, in 1989, was political rather than scientific? I do not know how to answer these questions. And I do not know if a less radical explanation could not be found. One may suspect, for example, that bacteria, for some reason, contribute to the redistribution of ^{202}Hg within the rat kidney. This would change the counting geometry and explain the abnormal decrease of the counting rate. (The radioactivity of that isotope consists of gamma rays of 0.28 MeV and of beta rays of 0.21 MeV.)

At the same conference (ICCF10 in Cambridge, August 2003) I met a Ukrainian scientist from Kiev. He is also deeply involved in transmutations of chemical elements caused by bacteria. Vladimir Vysotsii and Alla Kornilova are the authors of a recent book "Nuclear Fusion and Transmutation of Isotopes in Biological Systems." (Mir, Moscow, 2003, ISBN 5-03-003647-4). The book has two parts, the original Russian text and its English translation. Vladimir gave me a dedicated copy of this interesting book.

It will take some time before I grasp everything. Here is an example of transformation of Mn into Fe. The beauty of this experiment is in its ability to detect ^{57}Fe only (via Mossbauer spectroscopy). Bacteria, whose metabolism is based on iron, but not on manganese, were grown in heavy water containing $MnSO_4$. The amount of ^{57}Fe in water, before introducing bacteria into it, was minimized; it was too small to measure. This was not surprising; natural iron has only 2% of that isotope. But 72 hours later, after iron-hungry bacteria were allowed to grow in the ironless environment, the situation was very different. The amount of ^{57}Fe was much higher than the threshold of detection. Several control experiments, for example, using ordinary water under identical conditions, lead to a conclusion that the progressive accumulation of ^{57}Fe was due to the $^{55}Mn + ^{2}D \rightarrow ^{57}Fe$ nuclear reaction.

Yes, I know that the coulomb barrier of several MeV should prevent such reactions. The coulomb barrier theory has been validated in experiments involving so-called hot plasma. But it would be a mistake, I think, to reject experimental

data on the basis of a disagreement with that theory. Being applicable in the hot plasma environment it may turn out to insufficient to understand some unknown processes taken place in crystals or in bacteria. The only way to justify a rejection of experimental data is to show an error in a procedure used to validate them. Experimental findings confirmed by several investigators should be taken very seriously. How else could limitations of theories be explored? A theory attempting to overcome the coulomb barrier objections to cold fusion has been described at the conference by an MIT professor, Peter Hagelstein.

108) Another experiment for students ?

Ludwik Kowalski (August 31, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

1) The cold fusion experiment for students, described in item 103, focuses on excess heat. Let me describe an experiment for students which some of you might be able to perform. It was inspired by the talk of Dr. Richard Oriani at the 10th International Conference on Cold Fusion, by a conversation with Dr. John Fisher (also at ICCF10), and by an email message received from Oriani after the conference (see below). This experiment is designed to reveal alpha particles resulting from nuclear reactions presumably taking place during the electrolysis. An ordinary tap water, rather than expensive heavy water, was used to prepare the electrolyte.

2) Alpha particles were detected in plastic chips similar to nuclear emulsions (but much less expensive and much easier to use). The detector is called CR-39; it is a sheet of transparent plastic. Alpha particles, for example, from radon, create latent tracks which can be made visible (through a microscope) by developing the chips in hot KOH. The CR-39 detectors are commercially available from several suppliers. One place to obtain them is:

Track Analysis Systems Ltd
H H Wills Physics Lab
Tyndall Avenue
Bristol
BS8 1TL
U.K.
Tel (0)117 9260353
Fax (0)117 9251723
web www.tasl.co.uk
e-mail apf@tasl.co.uk

Here is what this supplier wrote to me in January 2003. “Thank you for your inquiry. We do not have any agents in the US -- we sell directly to customers. The prices depend entirely on what you require. If you can say the sizes and quantities you are interested in, I will be pleased to make a specific quote. For example: pieces 25x25 mm, with an engraved (incrementing) number, cost 1.75 US dollars each. We can quote for sizes from 10x10 mm up to 275x280 mm. Our material is carefully produced to high quality standards, and each batch of production is tested for background and track response. For the US, we have a minimum order quantity of 100 US dollars.”

3) To gain experience I exposed a CR-39 chip to a ^{241}Am source of alpha particle (removed from a fire alarm detector). After an exposure of 30 seconds the chip was kept in hot KOH (70 degrees C) for six hours. Then it was washed in water and placed under an ordinary microscope (magnification 40 or 100). Pits due to alpha particles were visible in the exposed area while the surrounding areas had much lower track densities. These detectors are often used to measure concentrations of radon in different locations. Dr. Oriani placed the chips into the electrolyte of a cold fusion cell and observed an excessive number of tracks. **Here is what I wrote to him after the conference:** “I am a physics teacher who is trying to develop a convincing cold fusion demo for students. Your CR-39 experiment is a good candidate. I talked about this with John Fisher and he suggested that I contact you about details.

1) What was the concentration of Li_2SO_4 in water?

2) How many volts and how many amps?
3) How large were the areas of your Ni and Pt electrodes?

Suppose I do an experiment under about the same conditions as you did and that no extraordinary event (which you described) occurs. I want to bring the number of alpha pits to at least 10 per field of view (magnification 100).

4) How long should a CR-39 be kept in the tube (days, weeks, months, ...) ?

5) Is it better to keep CR-39 in the liquid or above the liquid?

Here is Dr. Oriani's reply: " ... It's a pleasure to answer your questions because I am delighted that you will try to convince your students that so-called cold fusion is a real phenomenon. Answering your specific questions:

1) The concentration that I used is 2.3 g of Li_2SO_4 in 100 cc of H_2O, but you can deviate from that to some extent.

2) I usually electrolyzed for 3 days starting at about 100 mA, the next day at about 200 mA, and the third day at about 300 mA, letting the voltage be what it needs to be to achieve those currents.

3) The cathodes were bounded by an O-ring whose diameter is 1.4 cm, and the anode is a flat Pt spiral of about 1 cm diameter. The CR-39 detector chips are suspended within the electrolyte preferably above the anode, or in the gas in a heated section of the electrolysis cell kept at about 65 C and separated from the surface of the electrolyte by a nickel disc of diameter slightly less than the id of the electrolysis cell. Its purpose is to mitigate the impact of electrolyte mist upon the chips.

4) The detector chips should be in the cell for the entire duration of the electrolysis. I suggest that you place chips both in the liquid and above the nickel disc in the vapor.

5) You must remember that radon in the air and cosmic rays will produce tracks on the chips during handling and photography or viewing under the microscope. Hence you must examine the chips by etching in 6.5 N KOH at 65 C for about 10 hours and recording the tracks visible before electrolysis, then do the electrolysis and repeat the etching and examination of the chips at exactly the same areas that you examined and recorded prior to electrolysis. [I suppose the photos taken before the electrolysis were compared with photos taken after the electrolysis.]

6) Of course you also need to carry out controls, doing exactly the same operations to the control chips as for those exposed in the cell, but the control chips are not exposed to electrolysis. For further details I refer you to our paper published in Jap. J. Appl. Phys. [in 2002] and available at www.lenr-canr.org I hope that you succeed. Feel free to write again if something is not clear."

In the correspondence that followed Dr. Oriani provided me with data shown below. Referring to the table he wrote: "The numbers are new tracks per cm^2 of chip area. That is, I count the tracks that appear after electrolysis and the second etch and subtract from that number the tracks that appeared after the first etch before electrolysis and divide that difference by the area on which the tracks were counted. [The results are shown in column 2]. Exactly the same area was counted after each etching. The same procedure was applied to the control chips; they were immersed in solution of the same concentration as were the actives, in fact from the same batch, the sole difference being that they were not exposed to electrolysis. [The results are shown in column 1]. If you want the absolute number of new tracks, multiply the tabulated numbers by the area of a chip, roughly 0.64 cm^2. Note that the data entries were artificially organized in order of decreasing magnitude. All experiments were done with solution from one large batch."

Oriani and Fisher
published in July 2002

As indicated by Oriani, the lines in the above table have been sorted according to new track densities; a monotonic decrease of densities in 16 consecutive experiments would be very unlikely. The second column shows that a single 3-days exposure produced very different new track densities when experiments were repeated. Commenting on this Dr. Oriani wrote: "The overlap of the two distributions is owing to two facts: not every electrolysis [experiment] produces a nuclear reaction (I do not know the reason), and the reaction may have taken place away from the chip. This second reason is a strong possibility because I often see one side of a chip with a large number of tracks whereas the other side has only a number characteristic of the controls. I appreciate that for a demonstration you would like an experiment that always produces the expected result. However, we are not yet able to have that assurance in this field. Because of the two reasons discussed above we must rely on a statistical analysis of a large number of experiments unless, as you say, one gets lucky and sees a 'shower' as I showed in my lecture." Yes, reproducibility is a big issue, as in most cold fusion experiments.

I do not know how to explain large changes (order of magnitude) in new track densities from control samples. It is significant that the method used allowed to discriminate against tracks which were formed in CR-39 before experiments. Would the use of distilled water be preferable? It depends on the role of impurities in cold fusion phenomena. Several scientists speaking at the conference (ICCF10) think that successes and failures of cold fusion phenomena depend on uncontrollable impurities, often below the ppm level. The results presented by R. Oriani and J. Fisher are remarkable because new track densities in control samples are always much lower than corresponding densities in active samples. At least this aspect seems to be highly reproducible.

Knowing that I plan to share his data with other teachers Dr. Oriani wrote: "you have my permission to share and operate on these data in any way you please." In a message commenting on the draft of this document he added: " I hope that your web site causes someone to replicate the experiment." I also hope that this will happen. It would be a great student-oriented project. The task is well defined: to confirm or not to confirm results published in a refereed journal in Japan. I think that the journal would publish a serious study of that kind. Too bad that I did not meet Dr. Oriani when I was learning how to use CR-39 detectors last spring (for an experiment which turned out not to be necessary). I was on sabbatical at that time; now I am too busy teaching. Perhaps I will have more time in the Spring semester, or after I retire in May of 2004.

POST SCRIPTUM:
The CR-39 detectors can be cut into small pieces, for example 1 by 1 cm, by using regular scissors. They can also be labeled by using a sharp needle. No darkness is required, as with photographic emulsions. A team of Russian scientists (A. Lipson, now working in the University of Illinois, and A. Roussetskii, from Lebediev Institute in Moscow) managed to distinguish alpha particles from protons by using CR-39 detectors in combination with very thin filters. But such task is much more difficult than with nuclear emulsions. The unique advantage of CR-39, as illustrated by R. Oriani and J. Fisher, is that a chip can be "developed" twice.

Suppose the first development produced 37 tracks near a recognizable scratch on the detector's surface. This is the background due to previous long time exposure to radon, cosmic rays, etc. The chip is then used in an experiment and developed again. The previously seen tracks are still visible but an additional set of new tracks appears, for example, 10. Then we know that new tracks are real; they were created when the experiment was performed. This approach is much better that using two different chips, that is: getting 47 from one chip (background plus signal), getting 37 from another (background only) and subtracting these two numbers to get 10. The net result obtained in that way can not be distinguished from statistical fluctuations.

109) Cold Fusion: Fire from Water

Ludwik Kowalski (September 8, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

A week after returning from the 10th International Conference on Cold Fusion I was trying to explain the essence of the cold fusion phenomenon to my sister-in-law, Helen Knott. She wanted a very simple explanation; the video cassette I was showing her was "not good enough," she said. In my opinion that cassette ("Cold Fusion: Fire from Water" authored by E. Mallove and J. Rothwell), available at

http://www.infinite-energy.com

is very good for people who have studied some physics and chemistry; I was not aware that a person without such education might not be able to follow the narrative. This brief summary is dedicated to Helen. It is an introduction that I will make before showing the cassette to a nonscientific audience. I plan to do this at Montclair State University, probably in October or November. Am I right to assume that at least 99% of the general population knows nothing about the cold fusion controversy?

Burning of wood, coal and oil consist of chemical reactions. Each gram of fuel yields a certain amount of thermal energy. But stars, like our sun, have no such chemical fuels; their thermal energy is generated from nuclear reactions, as in a hydrogen bomb. The fuel used in these thermonuclear reactions is hydrogen. The reaction is called "fusion" because two tiny atomic nuclei must fuse into one larger nucleus before the energy is released. The idea of a slow non-explosive "nuclear burning" is not new; scientists started investigating this possibility in early 1950s. For a small fraction of a second they raise the temperature of hydrogen to millions of degrees hoping to get more energy out of a system than the amount of energy needed to operate it.

Unfortunately, progress was much slower than anticipated. Tens of billions of dollars were spent each year but the amount of thermal energy generated in huge fusion furnaces continues to be a small fraction of the energy used to operate them. It is important to emphasize that a great deal of understanding resulted from decades of these investigations. We know that the possibility of building thermonuclear fusion devices producing more energy than is necessary to operate them is real but decades of additional research will be needed to achieve this goal. That is why the entire scientific world was galvanized when two scientists from the University of Utah,
Fleischmann and Pons, made an announcement (in 1989) that they had a device producing more energy than what was needed to operate it. The device was as small as a can of beer and could be operated from a car battery. The cost of materials needed to build a demonstration device was less than $1000.

Even today, nobody understands what was going on, but the amount of excess heat generated was much larger than what could possibly be attributed to chemical reactions going on inside. It was thus hypothesized that nuclear reactions of some kind were taking place in the relatively cold environment. Utah scientists, and others who were able to reproduce the effect, did not say that the reactions were the same as those going on in hot fusion furnaces. But they were criticized as if that was the essence of their discovery. The opponents coined the term cold fusion and convincingly argued that experimental facts, known in 1989, were not consistent with the cold fusion mechanism. Furthermore, many scientists failed to observe excess heat in their laboratories.

On that basis the extraordinary claim of Utah scientists was officially declared to be invalid (by a panel of experts appointed to investigate the phenomenon). Subsequently, the US Department of Energy, and other government agencies, decided not to support cold fusion research. Furthermore, editors of major scientific journals decided not to

publish articles devoted to such research. Despite these unprecedented decisions at least one hundred researchers, in several countries, continued to investigate the puzzling phenomenon. Most of them are highly qualified to conduct such research; their expertise was recognized long before the discovery of cold fusion. Fleischmann, for example, was a widely respected electrochemist and a professor at the University of Southampton. He was a Fellow of the Royal Society in England and the author of more than 200 scientific publications. In 1979 he won the medal for Electrochemistry and thermodynamics. Six years later he was awarded the Palladium Medal by the U.S. Electrochemical society. Between 1970 and 1972 he was the president of the International Society of Electrochemistry.

Unlike supporters of other controversial claims, such as UFOs, healing with copper brasletes, perpetual motion machines, etc., nearly all cold fusion investigators are Ph.D. scientists, often retired, who have been associated with prestigious universities and research laboratories. Yet they have been “excommunicated” from the rest of the scientific community as practitioners of “pathological science.” In my opinion, there were no need to condemn a field in less that a year after the first discovery was announced. The field should have been allowed to develop, like any other thread of scientific investigations, in order to decide, scientifically rather than administratively, about the validity of its claims. Some claim that the official “blacklisting” was motivated by political, rather by scientific, reasons. I am not qualified to validate this claim. In my opinion, the arguments used by critics in 1989 are at odds with many recent findings, and a second national evaluation of the entire field, by an appointed panel of experts, is needed.

I also think that the main emphasis should be on scientific aspects of cold fusion; it is premature to argue about practical applications at this time. Promising too much, and too early, was one of the mistakes of those who supported cold fusion when it was originally announced. The present situation is highly abnormal. This can be best illustrated by the titles of two recently published books, that of Robert Park and that of Charles Beaudette. The title of the first book, published in 2000, is “Voodoo Science; the Road from Foolishness to Fraud;“ the name of the second book, published in 2002, is “Excess Heat. Why Cold Fusion Prevailed?” No, cold fusion did not prevail, it is still treated as it were pseudo science. To convince me that cold fusion is real a person should allow me to perform an experiment in which nuclear events, such as progressive accumulation of helium, or tritium, is demonstrated. Such observations have been reported by many investigators but, in the current abnormal situation, I want to see things for myself. I would also be convinced if I could see that isotopic compositions of various chemical elements change in a cold fusion apparatus.

I do believe, that sooner or later, perhaps in fifty years, the cold fusion puzzle will be resolved, one way or another. This optimism is justified because “the scientific process is self-corrective. This unique attribute sets science apart from most other activities. The scientific process may on some occasions move slowly, sometimes even along a circuitous path. The significant characteristic of the scientific method, however, is that in the end it can be relied upon to sort out the valid experimental results from background noise and error.” This statement was made by John Huizenga, the author of a highly critical book about cold fusion, published in 1991. The title of that important book was "Cold Fusion: The Scientific Fiasco of the Century."

The cold fusion episode will never be forgotten; perhaps it will be viewed as the beginning of a very significant new period in the history of science. Suppose that the claim for nuclear reactions occurring in so-called “cold fusion” experiments are definitely validated by mainstream scientists. In that case the problem of blacklisting of a large group of recognized scientists by the so-called “scientific establishment “ will be debated. Something will be done to make sure that a similar event does not happen again. On the other hand, the definite rejection of cold fusion claims will result in focusing on another issue. How come that so many highly qualified scientists, in so many countries, were able to deceive themselves, for decades, by phenomena that were not real? How do we know that phenomena of similar massive self-deception do not exist in other areas of science? Something will be done to improve scientific methodology, to make sure that a similar long-term blindness does not occur again. Of course, such issues belong to the realm of social interactions among scientists. That is why the “cold fusion episode” deserves to become a topic of general interest.

111) A political campaign using C.F. ?

Ludwik Kowalski (September 13, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Today I received an interesting e-mail message from Dr. Eugene Mallove, editor of Infinite Energy Magazine and author of a well known book “Fire from Ice” (John Wiley and Sons, Inc., New York, 1991). The message (see below) is a call for using the cold fusion issue in the upcoming presidential campaign. I do not think this is appropriate. Cold fusion research is still in its infancy and nobody claims that practical industrial applications are on the horizon. Cold fusion is no closer to practical applications than hot fusion was half a century ago. The path from recognizing the possibility of an application to a commercial success is highly unpredictable. Promising electric energy “too cheap to meter” was one of the mistakes of hot fusion promoters. That was in the late 1950s; and they were in a much more favorable situation than cold fusion researchers are today.

Like Eugene, whom I had pleasure to meet at the 10th International Conference on Cold Fusion, I think that a panel of experts should be appointed, for example, by the National Academy of Sciences, to investigate the validity of cold fusion claims formulated since the initial 1989 report. Physics teachers, like myself, need official evaluations in order to know how to answer questions about cold fusion. My recent letter to the editor of The Physics Teacher (published in June, 2003) is an appeal for a formal investigation of new cold fusion findings.

But I would be against politicizing this issue in a presidential campaign. Why should cold fusion, and not, for example, solar energy, be singled out? The first goal of the cold fusion community (if it were organized) would be to develop a reasonably reproducible device demonstrating nuclear phenomena at ordinary temperatures, for example, emission of protons, tritons or alpha particles, production of chemical elements with abnormal isotopic ratios, accumulation of helium (correlated with excess heat generated at the rate of 23.6 MeV per atom), etc. Such devices have been built in several countries, including the US, but they are not available to most of us. The second goal of an organized cold fusion community would be to develop a theory of cold fusion phenomena.

Attempts to build useful devices are not likely to succeed at the present level of our understanding of cold fusion. That is why it is too early to promise anything practical, especially in a political campaign. Yes, I am aware that the rapidly aging cold fusion community is highly dispersed and leaderless (see the footnote). Each scientist, or group of scientists, works as if cold fusion were just another officially recognized field of investigation. And each believes that his work will finally convince all honest skeptics. The total number of active cold fusion scientists, worldwide, is probably about the same as in the Manhattan Project. But in the last 13 years they have not been able to convince the rest of the scientific community that their claims are valid.

Performing beautiful experiments is not enough; something else is needed to convince the entire scientific community that cold fusion phenomena are either real or false. Eugene is right; a second national review of the cold fusion field could clarify the current, very unfortunate, situation. Ten years of dedicated research, done by hundreds of top scientists, worldwide, should not be ignored. It should be evaluated by an appointed panel of experts. Why should their “labor of love,” thousands of man-years of sophisticated research, be wasted? The panel should be created before the scientists, and the instruments they constructed, become too old to be useful. The question is how to make this happen?

The initiative, in my opinion, should come from honest mainstream scientists, teachers and engineers. They, not the general population, should be approached by cold fusion scientists and asked to examine recent findings. Professional conferences and journals provide an ideal ground for this kind of initiative. I am aware that some editors and conference organizers think that cold fusion is voodoo science and that society should be protected from it as from a dangerous

disease. They place cold fusion researches in the same category as fraudulent market manipulators, believers in UFO and practitioners of copper bracelet therapy. A way of bypassing dogmatic officials must be found. My own interest in recent cold fusion findings was triggered, one year ago, at a technical conference at which cold fusion researchers were allowed to make presentations. I do not know what else can be done; a political campaign suggested by Eugene is not likely to result in the second national review of the cold fusion field. Here is what Eugene wrote to me, and probably to many other conference participants:

"This will be my question to ALL presidential candidates that I happen to encounter during the New Hampshire Presidential Primary season, which is already well underway in September 2003:

****

Candidate X: I'm Dr. Eugene Mallove of Infinite Energy Magazine in Concord.

I'd like to ask what YOUR position is on an issue that transcends and yet encompasses ALL the other issues that you and other candidates talk about — peace, freedom, the economy, healthcare, the environment, and - of course - energy independence:

During your campaign will you ask for and DEMAND a review by the US Department of Energy or by the National Academy of Sciences of the now overwhelming body of scientific evidence that supports cold fusion/low-energy nuclear reactions energy? This is clean, abundant energy from water, a scientific discovery made in the United States and announced in 1989 — and then crushed, as it was being confirmed, by arrogant vested academic and bureaucratic interests?
****

A Yes or No answer will do!

If anyone wishes to post this question elsewhere, or to ask it himself or herself of any candidate -- in ANY primary state, I would be thrilled. Please let me know if any responses are received from any of the presidential candidates or their senior advisors. We will post responses on our web site and elsewhere."

Ludwik's footnote:

1) The only "leader," as far as I know, is a person chosen to be the chairman of the next cold fusion conference. The responsibilities of that person are limited to conference-related tasks.

2) There is also a web site (www.lenr-canr.org) maintained by a dedicated individual, Jed Rothwell. Its function is to inform rather than to direct scientists. That web site became an excellent source of downloadable cold fusion papers.

3) A pier-reviewed electronic journal devoted to cold fusion research has just been created. Will the editor of that journal, professor P. Hegalstein from MIT, become a leader (as Oppenheimer or Grove were for the Manhattan Project)? I do not think so.

4) Those who reject cold fusion claims, on the other hand, are highly organized. That group consists not only of an army of active research scientists, for example, those working in national or industrial laboratories, but also of official managers of money available via institutions, such as NSF, DOE, APT, NAS, etc.

111) Photos of Fleischmann and Jones, August 2003

Ludwik Kowalski
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043.

Return to the clickable list of items

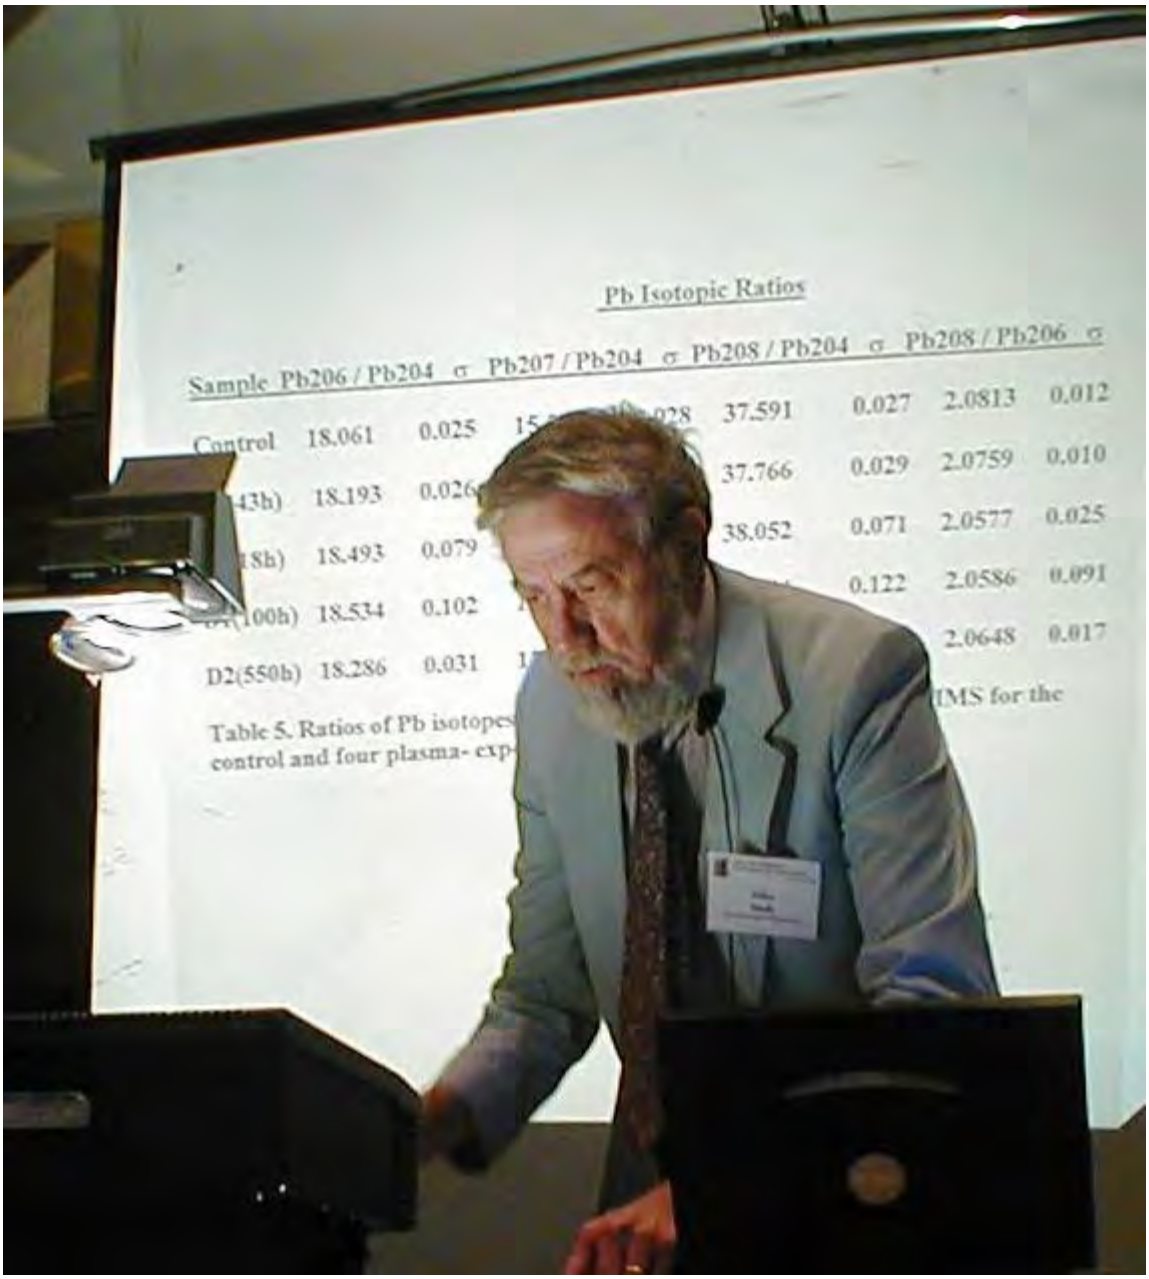
This item contains pictures of Martin Fleischmann and Steven Jones. I took these photos during the 10th International Conference on Cold Fusion (Cambridge, Mass., August 2003). And I was not able to resist temptation of showing myself in the company of at least one of these two scientists.

Martin Fleischmann with a glass containg cold fusing ice.

==========

Steven Jones and myself.

==========



And this John Dash, a physics teacher from Portland State University at the conference presentation. John also brought a group of students to demonstrate their own cold fusion projects (see items #103 and #98). I suppose he is the first teacher in the world to direct a student project devoted to cold fusion research.

==========

A high school student showing a simple excess heat setup.

NOTES:

1) Prior to 1989 Fleischmann (with Pons, who is no longer active in the area of cold fusion) and Jones were using similar electrolytic cells to study completely different phenomena. Their laboratories were only about 20 miles apart but the two Utah scientists did not know of each other's work. Fleischmann was a chemist, Jones a physicist; each was known as a top scientist in his field. They intended to cooperate, to study the phenomena systematically, and eventually publish the result of findings. That would have been the normal way of conducting science.

2) But, due to unusual circumstances, the cooperation did not materialize. After 1989 the scientists became victims of bureaucratic manipulation and their work the subject of an unprecedented public debate. The scientific community became polarized; some rejected cold fusion findings on the basis of presumed errors, incompetence or fraud; others took the data seriously and continued investigating. Most scientists and teachers (among those who are still interested in the controversy) wait for an official verdict from a team of appointed experts. They are not equipped to conduct sophisticated cold fusion experiments. It turns out that most questions asked by early critics have been answered by those who continued conducting research. But are the answers satisfactory? The appointed panel of unbiased experts should answer such questions. In my opinion our National Academy of Science, or National Science Foundation, should take the initiative. The focus should be on scientific claims, not on practical aspects of cold fusion. It is premature to speculate about practical applications at this time.

Return to the clickable list of items

My oral contribution at the 10th International Conference on Cold Fusion was made in the form of Power Point slides. The content of these slides has already been posted as item #80 on this web site. Several days ago the manager of the LENR-CANR web site, Jed Rothwell, suggested that I write a paper, based on slides, for the conference proceedings. What follows is the paper I wrote today; it will probably be downloadable from the Library of the LENR-CANR site < http://www.lenr-canr.org >. My poster contribution to the conference is also going to be downloadable from that site.

112) The dilemma of a physics teacher

Ludwik Kowalski
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043 (9/20/03)

This presentation is dedicated to an unknown high school chemistry student who sent me an e-mail message last spring. She wrote:

"Help! My name is Maggie Johnson and I am a sophomore at Saratoga High School. In my chemistry class, I am doing a project on Cold Fusion. I was looking on the Internet for websites on Cold Fusion, and I came across links to your Cold Fusion items. I was wondering if you could give me some advice or information?"

1) A year ago I would have replied that cold fusion is pseudoscience. **But I am no longer comfortable with this kind of reply.** Why am I not comfortable? My first opinion was based on Huizenga's famous ERAB report. I knew the author personally and I respected him. His criticism of cold fusion was convincing because it was based on the idea that cold fusion is a thermonuclear reaction between two colliding hydrogen ions. Experimental data certainly do not support such an idea. But who made this claim? Only the popular press and those who criticized cold fusion. Fleischmann and Pons, who discovered excess heat, speculated that some kind of nuclear processes might be responsible for what they observed. The very name "cold fusion" was highly unfortunate because it misled many scientists, including myself. Who invented this term? Was it introduced deliberately (as a straw man) to discredit the nascent field of research? I have no answers to such questions. But I suspect that this misleading term will survive the controversy; that is why I use it here.

2) Two other factors helped to discredit the cold fusion field in many minds: the claim that experiments in this area are extremely simple, and that practical applications are going to be possible very soon. Again, I do not know who the authors of such claims were. Those who criticize cold fusion today, Park in the US and Kruglyakov in Russia, essentially repeat Huizenga's arguments. **What was convincing in 1989 is no longer convincing today.** Why do they ignore the generation of helium? Why do they ignore more sophisticated calorimetry? Why do they ignore unnatural isotopic ratios? Why are they not at this conference listening to presentation of new data and defending their own ideas? That is another set of questions that I am not able to answer. Ignoring experimental data is not an acceptable method of addressing a scientific controversy.

I am still not convinced that cold fusion is real. But I no longer say that cold fusion is voodoo science. I do read papers downloadable over the library of the Internet web site < http://www.lenr-canr.org > and I share what I understand with other physics teachers < at http://csam.montclair.edu/~kowalski/cf/ >. Feel free to explore my short essays and to share them with others. **Why am I still puzzled?** Because everything I know about nuclear science goes against the idea that

nuclear reactions can be induced by chemical processes at ordinary temperatures. I wish I had a chance to personally participate in experiments generating extraordinary results. But, like most teachers, I have no access to a sophisticated laboratory which would be needed to verify accumulation of helium and heavier reaction products. I read about such phenomena and I am impressed. But I would be more comfortable if the reported results were examined and officially confirmed by an appointed panel of experts.

3) I am also puzzled by the fact that **hundreds of sophisticated research scientists exploring cold fusion over the past 13 years have not yet developed a reliable demo for teachers**; windows of opportunity did exist in several countries. Teachers need experiments that can be performed with simple instruments available in schools, such as Geiger counters and gamma ray spectrometers. Excess heat generated at a rate of about one watt is not convincing unless one is able to deal quantitatively with all possible chemical reactions taking place in the apparatus. Reproducible generation of excess heat at the level of twenty watts, or higher, for a long period of time, would be much more convincing to a physics teacher, especially if it could be correlated with emission of nuclear particles or gamma rays. Even a 70% reproducible demo would be useful; teachers know that some experiments, for example in electrostatics, do not succeed when humidity is too high. Cold fusion seems to depend on factors which have not yet been identified. Abnormal isotopic ratios, reported by many independent researchers, are extremely convincing but a typical teacher can not verify such data.

4) That is why I would be more comfortable if the reported results were examined by an officially appointed panel of experts. **A second national evaluation of the entire cold fusion field is definitely needed to clarify the situation.** I am also disturbed by the fact that some cold fusion data are reported in journals which also publish papers dealing with hydrinos, antigravity, rotational fields, quantum healing devices, etc. etc. I know that leading journals do not accept articles devoted to cold fusion and that many scientists share their observations via channels available to them. It is better to use these channels, they think, than not to publish. That is natural. But it would be better if claims based on speculative extrapolations from exotic theories (and perhaps on wishful thinking) were not mixed in with cold fusion claims which are basically experimental. Therefore I strongly support the announced initiative of starting an electronic peer-reviewed journal devoted exclusively to cold fusion topics. Voodoo science does exist and cold fusion researchers should separate themselves from it.

5) I am optimistic that the cold fusion controversy will be resolved, one way or another.
The optimism is based on the following quotation from what John Huizenga, the author of the ERAB report, wrote in 1989. "**The scientific process is self-corrective**. This unique attribute sets science apart from most other activities. The scientific process may on some occasions move slowly, sometimes even along a circuitous path. The significant characteristic of the scientific method, however, is that in the end it can be relied upon to sort out the valid experimental results from background noise and error." And here is another quote from the panel of appointed scientists responsible for the first national investigation of cold fusion. **"**The Panel recommends against the establishment of special programs or research centers to develop cold fusion. However, there remain unresolved issues which may have interesting implications. The Panel is, therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system." **Sympathetic attitude toward unresolved issues** is worth emphasizing.

6) What will be the verdict of history? Sooner or later, perhaps in 50 years, the cold fusion puzzle will be resolved (like the "puzzle of cybernetics," or the "puzzle of genetics," both in USSR). Only two outcomes are possible: (a) CF phenomena will finally be confirmed or (b) CF phenomena will not be confirmed. In each case one will have to deal with important social issues. Suppose that CF is confirmed. Then one would have to explain causes of a long-lasting conflict between scientists and administration. Suppose that CF is not confirmed. Then one would have to explain a phenomenon of massive self-deception involving hundreds of top scientists in many countries. In either case you will be recognized as participants of an important and **unique event in the history of science**.

Keep working to clarify the most intriguing scientific and social puzzle of the 20th century. I am certainly not the only physics teacher waiting for a consensus on cold fusion. Keep submitting good papers to traditional refereed journals, such as Physical Review, etc. **Do not be discouraged by frequently unjustified rejections** of your papers. Document such rejections and make them known to mainstream scientists. Deplorable confrontations with overly bureaucratic editors should also be exposed. Take advantage of the new electronic journal devoted to cold fusion. Dissociate yourself

from voodoo scientists and openly criticize them. Keep bringing cold fusion topics to scientific conferences devoted to areas overlapping with your activities. My own interest in cold fusion was reawakened at such a conference one year ago. Try to seek contacts with students, and with the general public. But focus on puzzling scientific results; it is too early to speculate about practical applications.

7) Let me finish by describing **my personal encounter with the process of rejection**. About half a year ago I wrote a letter to the editor of Physics Today. In that letter I described my own dilemma in dealing with cold fusion and asked for help. Why was my short letter rejected? Why was I not allowed to see what the referees wrote about it? Ironically, that letter was triggered by the article entitled "New APS Ethics Guidelines Address Research, Misconduct and Professional Responsibilities."
That article by Jim Dawson was published in the January 2003 issue of Physics Today. I welcomed the new guidelines and asked how a physics teacher can make sense of "cold fusion?" Was the research conducted in that area, in the last ten years, a "departure from the expected norms of scientific conduct" or did it "lead other scientists along fruitless paths?" I see no evidence that the data were "fabricated." As a physics teacher I am confused by the situation. Some say it was "a fiasco" while others say it was an "important discovery." How should teachers address this topic in the context of "public affairs between science and society," or in the context of discussing "institutional support for new ideas and innovations?"

After waiting several months I sent an e-mail message asking about the status of my letter. On Thursday, June 12, 2003, I received a reply from Dr. Marty Hanna, Letters Editor at Physics Today. He wrote: "So far, **I have a split decision on the possible publication of your letter.** I expect soon to have a tie-breaking input from a third reviewer. I will let you know as soon as I have a firm decision. Thank you for your patience." On Thursday, July 3 Dr. Hanna wrote " We have completed our review of your letter commenting on the APS ethics guidelines story in our January 2003 issue. Our decision, after some valuable discussion, is not to publish your letter. Thank you for writing and for your interest in Physics Today."

Unhappy about this I wrote "I would very much appreciate if you could send me the reports of the referees evaluating my letter to the editor." The immediate reply was "Please let me explain. I know that scientists who submit articles to peer-reviewed scientific journals expect reviewers to give them a critique of their letters. Physics Today is not, in the strictest sense, a peer-reviewed scientific journal; it is, instead, a **special-interest magazine** for physicists. Generally, my reviewers are staff writers and editors (all physicists) who may give me little more than 'thumbs up' or 'thumbs down' on a letter. As a rule, we do not give out the specific comments of the reviewers, because we consider them to be internal business. Thank you for your inquiry. I hope my explanation has helped."

The input from three qualified referees would be very useful to me. I am a member of APS and I expected a better treatment from my journal. This is not a healthy situation. Here is how it was described by Dr. E. Storms: "Serious scientists rejected 'cold fusion' in the past for good reason. These reasons no longer apply. **If science cannot correct a past rejection, then what good is the scientific method?"** Physics Today should promote exchanges of information among recognized physicists from different disciplines. It is an ideal place to ask the question formulated in my letter. Why did Dr. Hanna reject the letter after one of the referees recommended it? Which special interest is he protecting by not publishing the letter? What is wrong with asking for another evaluation of new cold fusion claims by an appointed panel?

113) Recent Papers of Steve Jones et al.

Ludwik Kowalski (October 9, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Many interesting papers were presented at the 10th international Conference on Cold Fusion (in Cambridge, August, 2003); some of them are already downloadable from the < http://www.LENR-CANR.ORG > web site. (click of ICCF10 PROCEEDINGS and scroll down to the list of papers). One of the most convincing evidence that the unexplained nuclear processes are real was presented by Jones et al. I am referring to his papers on the emission of neutrons and on the emission of charged particles.

1) The paper on neutrons reminded me of the old argument against cold fusion, absence of neutrons commensurable with the reported amount of excess heat. Suppose that excess heat, generated at the rate of 10 W, is due to well known thermonuclear fusion of deuterons. How many neutrons would be emitted in each second? To answer this question one must know that the amount of energy released from each thermal fusion event is about 3.5 MeV and that, on the average, one out of two events is associated with the release of a neutron. The other half are events associated with the release of protons. Converting 10W into $6.25*10^{13}$ MeV/s one finds $1.8*10^{13}$ fusion events per seconds and nearly 10^{13} neutrons per second.

This result is by many orders of magnitude higher that what has been observed. The unavoidable conclusion, reached as early as 1989, was that thermonuclear fusion can not possibly by a dominant mechanism generating excess heat in cold fusion experiments. Nuclear reactions taking place in cold fusion remain unexplained (production of heat without emitting a lot of neutrons) but one thing is clear, they are very different from well known thermo-nuclear reactions. Who invented the terms "cold fusion" and “hot fusion?” These unfortunate terms suggest the idea that cold fusion reactions are the same as hot fusion reactions. As far as I know, nobody has ever made such claim, except journalists and some book writers. Did they deliberately create a “straw man” to justify criticism of cold fusion? It is easy to criticize people for claims they do not make. The real claim of scientists studying cold fusion is that some, previously unknown, nuclear processes occur at metals loaded with hydrogen isotopes.

Therefore the issue of neutron commensurability, the central argument of those who criticize cold fusion, is totally irrelevant. Even a very small number of neutrons, emitted from metals loaded with hydrogen, is highly significant in the context of showing that something totally unexpected is taking place. That is why I was very impressed by the evidence, presented by Steve Jones et al., that neutrons have been detected. Their experiment was complicated by the fact that the emission rates are very small. The efficiency of detection of neutrons was maximized by using a setup of sixteen detectors in close proximity to metallic foils loaded with deuterium. The arrangement was able to detect approximately one out of ten neutrons, on the average. Additional complications resulted from presence of cosmic ray neutrons. That background was minimized by performing experiments underground (at the depth of 100 meters), by surrounding detectors with layers of additional absorbers and by using an electronic method of partial rejection of neutrons coming from the outside of the experimental setup. In a typical experiment, lasting several hours, the counting rate was about 8 per hour while the background was close to 2 counts per hour. Correcting such raw data for efficiency, and subtracting the background, the counting rate could be as high as 60 neutrons per hour.

Counting nuclear particles at a rate which is only four times higher than the background would not prevent one from measuring the net counting rate very accurately if sufficiently long periods of time, for example, several days or weeks, were available. Unfortunately such luxury is not yet available when particles are emitted from metallic foils loaded with deuterium. Conditions favoring nuclear processes have not yet been identified but, according to experimental data, they

often disappear after a couple of hours or so. Two methods of creating favorable conditions were used by Jones and his collaborators. The first method consisted of placing hot titanium foils into deuterium gas, the second consisted of treating foils with a weak D_2O solution of the unusual sulfuric acid, D_2SO_4. Not every treatment resulted in creating a nuclear active environment, the rate of success, as far as the emission of neutrons is concerned, was about 40%. In my opinion, this fact should not be used as an argument against cold fusion. Further progress can be very fast when a team of highly trained scientists is already able to observe a new phenomenon in one out of two or three experiments. Something significant is still not under their control and additional research is necessary.

2) The second paper presented by Jones and his coworkers described experiments with charged particles. In one experiment such particles, identified as 2.6 MeV protons, were counted at the rate of 2,171 ± 93 counts/hour. This was 400 times higher than the background and the repeatability was as high as 70%. Low energy protons, as described in item #28 (at my cold fusion web site), have already been reported by Lipson and his coworkers. The method of detection used by Lipson was based CR-39 track detectors while the method used by Jones was based on scintillation and silicon detectors. What can be more trustworthy than observation of protons by two teams of highly qualified scientists working in different laboratories and using different experimental techniques? Why are these experimental data ignored by those who keep repeating that cold fusion is voodoo science? The arguments used by them are based on what was known 13 years ago, not on knowledge accumulated in the last ten years.

The authors claim the "repeatability" exceeding 70%. I suppose that it means that nuclear particles are not always emitted from thin titanium foils loaded with deuterium. Why is it so? Because something is still not under control of experimentalists. But being successful 70% of time is very significant, considering the absence of a theory. Keep in mind that Jones's papers are downloadable from the above web site; my purpose is to summarize them, and to comment.

3) The third paper of Jones and Ellsworth, downloadable from the LERN_CANR.ORG web site, is very different from the first two. I would call it a vision paper; it focuses on old speculations of great importance to planetary science and on anticipated research in that area. Here is how the essential hypothesis was formulated by the authors. *"Natural geo-fusion in the earth occurs in or near the core of the earth, in the hot, hydrogen-bearing metals and minerals which are subjected to extreme off-equilibrium conditions deep in the earth. This hypothesis can be tested by measuring tritium and helium-3 in magmatic fluids from hot-spot volcanoes which tap magmas from plumes arising from the core-mantle boundary. In particular, magmatic waters of Kilauea, Loihi, and Icelandic volcanoes are predicted to contain significant tritium. We predict that tritium is also present in Jupiter, originating from 'cold' fusion in or near its metallic hydrogen core."*

In the second part of their short paper, the authors speculate that cold fusion might play an important role in nucleosynthesis of elements. Nuclear transmutations, reported by many cold fusion scientists, give credence to such speculations. The article ends with a list of sophisticated analytical tools available to the Department of Physics and Astronomy of Brigham Young University; Steven Jones is a professor in that department. I suppose these tools will soon be used to expand current investigations of new nuclear phenomena. Let me end with another quote from this article; it illustrates a healthy attitude of cold fusion scientists toward research.. *"Neither cold fusion nor cold nucleosynthesis is understood at present, nor are the results yet widely accepted by the scientific community. But as we continue to explore together, cooperative experiments at several laboratories giving positive results cannot be ignored much longer."* I hope the authors are right and that the entire field will soon be recognized as a valid area of useful research.

114) Another Debate Among Teachers?

Ludwik Kowalski (October 31, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

This morning (10/31/2003) I posted a message about cold fusion on the Phys-L discussion list. The immediate reply from Teacher 2, who often speaks for AAPT (American Association of Physics Teachers), made me think that other messages might follow. But they did not. It shows that many of us think that Phys-L is not an appropriate place to continue arguing about claims made by cold fusion researchers. There are two good reasons for this: (a) most of us are not trained is electrochemistry, highly accurate calorimetry, sophisticated nuclear detectors, mass spectrometry, surface chemistry, etc., b) it is a political issue often driven by emotions rather than by rules of scientific methodology.

Instead of responding on Phys-L list I will try to do this here. I will start by quoting both messages (hiding the identity authors) and by asking for comments to be sent to me in private. Your comments might enrich this item. Please write to me about evolving attitudes toward cold fusion. Samples of representative “voices from teachers” are worth collecting and preserving; future historians of science might benefit from their existence. Next year I plan to attend the 11th International Cold Fusion conference (in Marseilles, France) and this item might become an interesting poster presentation. I would also like to know how many people found my cold fusion web site worth visiting. It was created for you, and for your students. Should I continue using it to share what I learn and think about cold fusion?

Teacher #1 (myself):
My short summary of three recent papers of Steven Jones has been posted as item #113 at:

http://csam.montclair.edu/~kowalski/cf/

Steven Jones was one of three scientists whose work resulted in the "cold fusion" controversy, 13 years ago. Unlike Fleischmann and Pons, he is a physicist. Pons left the field while Fleischmann and Jones are still very active. Which Nobel Prize might they share, in physics or in chemistry? Physics. Is this possible? I think so.

But at this stage I would not recommend them (if I were entitled to suggest nominees). Instead I would argue that the second national evaluation of the entire "cold fusion" field is needed in view of recent findings. We, teachers, could play a role in asking for the second evaluation, as exemplified by my letter to the editor of our journal. Click below to see that letter.

http://ojps.aip.org/journals/doc/PHTEAH-home/letters/jun2003.pdf

My hope was that others will support the appeal (in responding to what I wrote) and that this will be noticed by NSF, NAS and AIP leaders. A letter to the editor, inspired by Jones' papers, for example, can have a significant impact. [Other research papers, presented at the Cold Fusion conference last August, are also downloadable from the same web site as Jones's papers. To get them go to http://www.lenr-canr.org , click on the ICCF10 and scroll down to the list of downloadable papers.]

Something will happen if many physics teachers write that they are confused by the present situation. We (and our students) have access to many good papers but our establishment keeps repeating old arguments that the entire field is "pseudo-science." Somebody should appoint a panel of experts to evaluate findings reported in the last ten years.

A letter to the editor of our journal, The Physics Teacher, can be submitted via e-mail. The editor is Dr. Karl. C. Mamola. The address is: < tpt@appstate.edu >

Teacher #2:
Ludwik, I disagree. TPT is not a research physics journal, and letters to the editor of TPT will not advance your agenda of reopening the issue of cold fusion. Such letters will actually alienate TPT readers like myself to your cause. Replicable research published in peer-reviewed physics research journals is required. Claims of conspiracy without results further discredits your cause.

Teacher #3: (in a message e-mailed to me in private):
In general I am supportive of cold fusion. However, I do not discuss the issue with others since I have found that most people, both pro and con, have more religious views on the subject than scientific. Anyway, that has been my experience, and that is my preference.

Teacher #1:
I am responding to Teacher 2 here (not posting it on Phys-L) because nobody else responded publicly. That is right; cold fusion papers should be published in peer-reviewed papers. TPT is not an appropriate place to argue either for or against the validity of claims made by experts. But it is an appropriate place, I think, to ask for help; most of us are not equipped for specialized research. Papers from high caliber scientists are available to us, and to our students; somebody has to help us to evaluate them objectively. I no longer know what to say when a student asks about cold fusion. A position paper published by an appointed panel of experts would help us to deal with a controversial scientific topic. What is wrong with expressing this opinion in TPT? By the way, my earlier attempt to ask for help on pages of Physics Today (in a letter to the editor) was rejected.

We need to know why claims made by cold fusion researchers should be labeled as not scientific; that seems to be the official policy of AIP. Do our leaders think that recent cold fusion claims result from a large-scale self-delusion involving hundreds of Ph.D. scientists? Do they think that it is a matter of international conspiracy to deceive? Do they think that fraudulent data are used to promote hidden agendas? If they do then they should try to convince us that such accusations are valid. They should support the initiative to appoint a new panel of experts. That panel, like the one appointed 13 years ago, would evaluate recent data and prepare us for dealing with recent claims. Who is against this and why?

By the way, what did teacher 2 mean by “claims of conspiracy without results?” And why did he say that I have an “agenda of reopening the issue of cold fusion?” I think that the 1989 ERAB report was valid; the evidence for unusual nuclear processes did not exist when that report was released. I see no need to argue about this. What I want to see is a critical examination of claims based on experimental data gathered in the last ten years. Need for such evaluation has been anticipated in the first report. How else should interpret the following quotes?: At this time “the Panel recommends against the establishment of special programs or research centers to develop cold fusion. However, there remain unresolved issues which may have interesting implications. The Panel is, therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system.” What is wrong with addressing the unresolved issues on the basis of new findings. And here is another quote. “The significant characteristic of the scientific method, however, is that in the end it can be relied upon to sort out the valid experimental results from background noise and error.” Who wrote this? John Huizenga, the chairman of the 1989 ERAB. I had a privilege of knowing John personally, and to learn from what he wrote about mechanisms of nuclear reactions.

Teacher 1 (myself):
Yesterday (November 7, 2003) I wrote:

> Such comments might help me to turn the item #114 into a compilation of
> interesting quotes. Please write about your evolving attitudes toward cold
> fusion. Samples of representative "voices from teachers" are worth collecting;

> to attend the 11th International Cold Fusion conference (in Marseilles, France)
> and item #114 might become an interesting poster presentation.

1) If you want your authorship to be known then please indicate so in your message to me. Otherwise you will be Teacher 5, Teacher 6, etc.; as in the poster I showed at the 10th conference. That poster, by the way, will appear in the book form (usual conference proceedings) at some times next year. They are working on it.

2) Feel free to focus on any aspect of cold fusion, either scientific or social. But try to be brief; emphasize what you think is original, new or highly significant.

3) Connections with teaching (questions students ask, projects they work on, comment they make, etc.) would be highly valuable. Also short descriptions of discussions you had with other teachers or parents (in the last ten years or so), etc.

4) No matter what the final verdict (perhaps in 50 yeas or so) cold fusion will be viewed as a strange event in the history of science, something comparable with what happened in Europe at Galileo's time. Help to document this event in the way that might be of some interest to future generations.

P.S.
5) Let me share an episode with you. The 10th conference had an open evening for the public. Not too many people came. One high school student asked: "what and where should I study if I want to become a cold fusion scientist?" In trying to answer I said something like this. "Do not focus on this right now. Learn physics, chemistry and mathematics; this will be useful to you no matter what you decide in four or five years. Cold fusion does not exist as a study track. Perhaps it is in the same stage at which aviation was 100 years ago. Or it may turn out to be a false alarm. Nothing would prevent you from being a cold fusion scientist if you decide to do so after establishing yourself in another technical or scientific field. Keep your eyes open and learn things which prepare you to be good in any field.

6) And here is something else. A conference organizer told me that he personally invited Robert Park, the APS spokesman and the author of the 2000 "Voodoo Science"
book, to come to the conference. The author had a "time conflict" excuse. A golden opportunity of learning about what is going on, or arguing that it does not make any sense, was missed. How does this differ from cases in which people refused to look at Galileo's telescope?

7) The conference was at a short walking distance from MIT. All professors (including experts in thermonuclear technology) were invited but they did not show up. What does this illustrate? But the conference chairman, Peter Hagelstein, was the MIT professor. He has been doing cold fusion research since 1989, mostly on the theoretical side.

Teacher 4:
Ludwik, I've read through about four of the links, including "what physics teachers think of CF" and the very first one, "Introducing cold fusion to students". I have to say it seems like a topic that really puts the Scientific method to the test, or perhaps the scientists! It seems like the debate revolves around whether or not the experimental discovery is worth considering, or if it was itself a fraud... I don't have time to read them all, but it's a very interesting archive. The clickable list of items is a bit daunting. You might wish to organize your webpage into a table, with links in each cell organized by sub topic, like "What is cold fusion?", "My articles regarding the subject", etc. It would make for an easier reading experience. ;)

Teacher 5:
I found your site last night and find it quite interesting. I am especially interested in the bits and pieces you have about the use of nano-particles. I read the comments made by Charles Kelly and have a few questions. First, I would consider myself to be a skeptic of "cold" fusion in that I am not convinced that it is real. However, at the same time, I have never been convinced that it has been disproved either. . . .

Teacher 6:
Recognizing the complexity of physical phenomena on solid surfaces Wolfgang Pauli once said that “surfaces are the invention of the devil.” Would he also say that “cold fusion is a diabolic science?” Cold fusion researchers are excommunicated as practitioners of forbidden cults. Terms like “pseudoscience” and “voodoo science” refer to heretical activities. The establishment, like the Inquisition, tries to protect true science from such influences. Fortunately for CF

researchers, the methods used against heretics today are not as brutal as they were five centuries ago.

Pauli is famous, among other things, for the discovery of a mystery particle called a neutrino. His investigation, as in the case of cold fusion, started when calorimetric measurements revealed an abnormality; heat generated in beta decay was produced at a rate much lower than expected. Instead of accepting the idea that energy is perhaps not conserved in beta decay, as suggested by others, Pauli postulated, on a purely theoretical basis, that beta decay is a three-body process. The third particle involved in the decay, the neutrino, is a carrier of missing energy. Experimental validation of this postulate occurred ten years later. In cold fusion the rate at which heat is generated was found to be higher than expected. What kind of processes are responsible for this? That is a big question. Scientists trying to answer it are not treated fairly, in my humble opinion.

115) They need your support

Ludwik Kowalski (November 17, 2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Today I received an e-mail message from Eugene Mallove. He is the author of a book about cold fusion, the chief editor of Infinite Energy magazine and the director of The New Energy Foundation. Dr. Mallove, whom I met at a recent cold fusion conference, is not an active research scientist. But he holds advanced degrees in astronautical engineering and environmental science. Eugene was a Chief Science Writer for the MIT News office when the discovery of cold fusion was announced in 1989. He is a fervent supporter of many energy-related causes. Personally I am not convinced that all these causes are equally valid. The practicality of cold fusion is possible but it is probably too early to anticipate benefits. The main emphasis, at this time, should be on fundamental research. The New Energy Foundation does support research projects, for example, a cold fusion investigation conducted by several high school students this year. The Infinite Energy magazine serves a very useful purpose summarizing research in many energy-related areas.

Mallove's e-mail message to me:

Ludwik,
I hope this note finds you well. Herewith, in the form of an MS Word attachment, is a distillation of the last 15 years of my experience in new energy -- with Internet site referencing. I hope that you appreciate its story and tone. There are some juicy quotes from several Nobel Laureates! I would very much appreciate your circulating this Appeal to those who might help our cause. The Nobel Laureate community and others should know about this! The field is greatly in need. We are at a critical turning point...

We recently received $100,000 from the New York Community Trust -- half to be awarded to grant applicants in new energy, and the other for support of Infinite Energy. The next issue of Infinite Energy (#52) has gone to press, many bombshell articles in it, as usual. You'll particularly like a table top experiment in thermodynamics, trivial to reproduce, that will make your head spin... Great for Physics Teachers -- a real monkey wrench into their self-satisfied complacency! Get a copy. All best,
Gene Mallove

Mallove's Universal Appeal:

New Energy Foundation, Inc.
(A nonprofit 501(c)(3) corporation)
P.O. Box 2816, Concord, NH 03302-2816

Universal Appeal for Support
for New Energy Science and Technology

by Dr. Eugene F. Mallove
President, New Energy Foundation, Inc.
Editor-in-Chief, *Infinite Energy* Magazine

TO ALL PEOPLE OF THE WORLD who have open-minded curiosity, good will, good judgment, and imagination. To Scientists and Engineers, Philanthropists, Environmentalists, Energy Developers, High Technology Investors, Healthcare Professionals, Journalists, Artists, Writers, Business People, Entertainers, and Political Leaders. Whether you are Conservative, Liberal, Democrat, Republican, Libertarian, or Anarchist, and whether you may be Agnostic, Buddhist, Christian, Jewish, Hindu, Muslim, Atheist, or some other category of spirituality, this message is directed to all people of good will like you …

Dear Friend:

Here are some thoughts by wise thinkers -- background for this urgent appeal for your consideration and support of research and development of radically new forms of energy. These are energy sources that have the potential to turn the present world order upside down and bring about a bright new day for civilization:

"The exception tests the rule." Or, put another way. "The exception proves that the rule is wrong." That is the principle of science. If there is an exception to any rule, and if it can be proved by observation, that rule is wrong.
Richard P. Feynman (1963), Nobel Laureate in Physics (1965)

The progress of physics is unsystematic…The result is that physics sometimes passes on to new territory before sufficiently consolidating territory already entered; it assumes sometimes too easily that results are secure and bases further advance on them, thereby laying itself open to further possible retreat. This is easy to understand in a subject in which development of the great fundamental concepts is often slow; a new generation appears before the concept has been really salted down, and assumes in the uncritical enthusiasm of youth that everything taught in school is gospel truth and forgets the doubts and tentative gropings of the great founders in its eagerness to make applications of the concepts and pass on to the next triumph…But each new young physicist…is in danger of forgetting all the past rumination and present uncertainty, and of starting with an uncritical acceptance of the concepts in the stage of development in which he finds them.
Percy W. Bridgman (1961), Nobel Laureate in Physics (1946)

American Nobel Laureate in Physics (1988) Leon M. Lederman is no proponent of research into *radical* forms of new energy; one might accurately call him a "pathological skeptic" based on at least one opinion he has voiced (see *The God Particle*, 1993, p.122). Nonetheless, he somehow *senses* that a physics revolution may be upon us. He said recently, "You can smell discovery in the air…The sense of imminent revolution is very strong." (*New York Times*, November 11, 2003, p.D12). He is much more accurate than he can imagine, but not at all for reasons that he would readily accept! Perhaps he may be thinking of esoteric academic physics subjects such "string theory" or "cosmic dark energy," but certainly not practical technologies based on radical new physics. Having the intellectual problems identified by physics Nobel Laureate P. W. Bridgman in the quotation above, Lederman has *not* been looking at a large body of research that *will indeed* revolutionize the foundations of physics and give us command of fantastic new forms of energy. Too bad for Lederman; and too bad for us all that he has not been paying attention. We could use the support of people like Lederman…if they would only come to their senses, that is, examine open-mindedly the validity of *experimental data* that challenges their cherished *theories*.

In an article in *Science*, November 1, 2002, eighteen experts reported that they examined all the *conventionally understood alternatives* to fossil fuels and found them all to have "severe deficiencies" in their ability to deal with environmental problems while also being adequate to growing planetary energy needs. Physics Professor Martin Hoffert, leader of that research group, told the press that the United States would have to undertake an urgent energy research crash program, like the Manhattan atomic bomb project or the Apollo lunar missions. According to the *New York Times* (November 4, 2003, D1), Hoffert stated that we would need "Maybe six or seven of them [massive projects] operating simultaneously…We should be prepared to invest several hundred billion dollars in the next 10 to 15 years." Well, I have news for these experts: The solutions to our energy problems are very close at hand, and they *do* require

initial research and funding, but not the billions of dollars that such Establishment "experts" are accustomed to from government largesse. Rather, all that is needed perhaps are only several tens of millions of dollars to create robust prototype electric power generators based on new energy physics discoveries *that have already been made*. That is what this Appeal for Support is all about: to raise consciousness and funding for these radical alternative new energy sources.

Question: Do you believe that it is possible that modern science has overlooked or ignored major scientific discoveries, which -- if developed into technologies— would revolutionize almost every aspect of civilization? **It has!**

I will not catalogue the many horrors and troubles of this world that could be reduced or eliminated with an abundant, safe, and clean, radically new form of energy, if it were to be embodied in widely used technologies. You know these troubles already. But I do want to tell you about a significant path toward solving many of these problems, which we can all begin to take *now*, but about which you may have heard very little. You may have thought that no such path could exist. Let me assure you that it does and that thousands of researchers are already on it. They have traveled this unbeaten path to a new era for far too long without adequate support. I should know, I happen to be one of them. Yes, we have not reached our goals, but thanks to meticulous scientific research, huge sacrifices, and tireless work against great opposition, these objectives are now much closer to being realized. The basic scientific direction of the path forward has already been mapped out. **We need your support to go further on the path and reach our common destination: A world of abundant, clean, and safe energy from sources that have no centralized geopolitical control.**

Please attend to this appeal. I am most certainly *not* asking you to accept my claims at face value. But you must read, consider, study or review the compendious referenced material, investigate it, and then, I hope, you will be moved to *take action*. If you still have questions about these claims that need answering, I and my colleagues are available to answer them with facts, not hand-waving.

Who am I to ask *anything* of you on behalf of others, whether your attention for these brief moments, or for your financial and moral support? I am a scientist and an engineer with two engineering degrees from MIT (1969, 1970) and a doctorate from the Harvard University School of Public Health (1975). I have worked all my adult life as a dedicated scientist, despite my engineer's stripes. I have always sought to learn how the cosmos really works, and I find this process to be an exciting, difficult, and unending adventure, despite those who so erroneously claim that we are approaching "The End of Science" or a "Final Theory of Everything." Apart from my work in government-funded research at MIT and Harvard and later in corporate settings, I have also broadened my horizons by writing about science as an author and a journalist. Articles by me and about me have appeared in such venues as *MIT Technology Review*, *The Washington Post* Sunday "Outlook" section, the *New York Times*, *Popular Science*, *Analog*, *TWA Ambassador* in-flight magazine, *Wired*, and *New Hampshire Magazine*. I have appeared on many national radio programs, and for a time in the mid-1980s I was proud to have been a regular science and technology broadcaster for The Voice of America.

I am telling you something about me, not to elevate myself, but to convey to you something of my experience, sincerity, and integrity. I have written three acclaimed science books for the general public: *The Quickening Universe: Cosmic Evolution and Human Destiny* (1987, St. Martin's Press), *The Starflight Handbook: A Pioneer's Guide to Interstellar Travel* (1989, John Wiley & Sons, with co-author Dr. Gregory Matloff), and *Fire from Ice: Searching for the Truth Behind the Cold Fusion Furor* (1991, John Wiley & Sons). The late Nobel Laureate in physics (1965) Julian Schwinger endorsed my book *Fire from Ice* with these words: "Eugene Mallove has produced a sorely needed, accessible overview of the cold fusion muddle. By sweeping away stubbornly held preconceptions, he bares the truth implicit in a provocative variety of experiments." (He shared the 1965 Nobel Prize with Richard P. Feynman and Sin Itiro Tomanaga.) I am most proud of this latter book, because it began a jarring quest that led to finding out not only dramatic new truths about new accessible forms of energy in nature, but more important for me and you, the following most astonishing truth about modern "official" science: *Official science is not really intent on truly expanding scientific knowledge, in particular when some very, very fundamental scientific dogmas and theories are put at risk.*

Here is how one famous nuclear science professor at my alma mater MIT reacted to my request to him in 1991 to study the summary reports from two pioneering Ph.D. scientists, who had compiled seminal reviews about frontier experiments in low-energy nuclear reactions (a.k.a. "cold fusion"). One of the reviewing scientists was 34-year veteran researcher at our Los Alamos National Laboratory (LANL) and the other was a leader of research at India's Bhabha

Atomic Research Center (BARC):

"I have had fifty years of experience in nuclear physics and I know what's possible and what's not!…I will not look at any more evidence! It's all *junk*!" -- *MIT Prof. Herman Feshbach, May 1991, on the telephone to Dr. Mallove*

I hope you recognize that the late Professor Feshbach's most unfortunate and ill-considered reaction was fundamentally unscientific. It reminds me of the Church leaders at the time of Galileo, who refused to look through Galileo's telescope at the Moon or at Jupiter, because they "knew" that nothing new could be seen! Yes, many modern scientists are filled with catastrophic hubris; they have become in many ways mere "technicians of science," and guardians of what amounts to a pernicious "Holy Writ." *Don't bother me with the experimental evidence, my theory can tell me what is possible and what is not!*

If by chance you are one of those who believe that "all is well in the house of science" and that "official science" can be counted on to behave itself and always seek the truth --even in matters of central, overarching importance to the well-being of humankind -- you are sorely mistaken, and I could prove that to you with compendious documentation. (If you want to read what happened at just one institution, MIT, when a paradigm shift threatened established *hot fusion* research programs and "vested intellectual interests" such as those Prof. Feshbach so vehemently defended, read my 55-page report about this monumental tragedy at www.infinite-energy.com.) But as a first step, you should reflect on the broader history of science, which is so fraught with revolutionary leaps and paradigm shifts. These have often been made against great opposition -- with revolutionary data staring an older, unaccepting generation of scientists right in the face! Read this Appeal carefully and then reconsider your opinion about who is telling the truth and who is defending falsehood about revolutionary new prospects for science and civilization.

For almost nine years I have been the editor of *Infinite Energy*, the magazine of new energy science and technology. Though it is now small in circulation, *Infinite E*nergy is received worldwide in some forty countries. And, *Infinite Energy* is distributed to newsstands across the United States and Canada. My friend and colleague, Sir Arthur C. Clarke, has supported with words and resources some of our efforts on behalf of new energy. The research that *Infinite Energy* covers suggests that there are at least three major categories of radically new sources of energy that civilization is on the verge of being able to tap and reduce to practical technologies. These are the completely new forms of energy for which this Appeal for Support is being issued. *New Energy* is the term that we apply to new sources of energy that are currently not recognized as feasible by the "scientific establishment," but for which overwhelming and compelling evidence exists, we suggest, in at least these major categories:

Category 1. New hydrogen physics (a.k.a. "cold fusion," more generally Low-Energy Nuclear Reactions or LENR, "hydrino" physics, and other water-based energy sources. Copious technical and other information about this research may be found on these two diverse websites: www.lenr-canr.org and www.blacklightpower.com as well as our own site, www.infinite-energy.com. The upshot of this energy-from-water field is that within ordinary water there is a heretofore unimaginably large energy reservoir that may be as great as 300 gallons of gasoline energy equivalent within each gallon of plain water! This energy would be non-polluting, would have no hazardous radiation, and would, in effect, have a zero fuel cost. Only one cubic kilometer of ocean water would provide energy equivalent to all the known oil reserves on Earth. In responding to a special plea by Sir Arthur C. Clarke, the White House requested from me a technically-based Memorandum on this topic in February 2000. This 8,500-word Memorandum, "The Strange Birth of the Water Fuel Age," was submitted to the Clinton Administration and later to the Bush Administration. It is now posted on www.infinite-energy.com. It asks for a review of the substantial evidence -- in particular the copious evidence developed over the past 14 years in U.S. Federal laboratories -- for this category of anomalous new physics energy. Unfortunately, apart from polite "Thank You" notes, no discernable action has been taken by either administration. The 10th International Conference on Cold Fusion (ICCF10) was held near and at MIT in August 2003. Actual public demonstrations of excess energy production in electrolytic cells occurred at MIT's Department of Electrical Engineering and Computer Science. *Wall Street Journal* science journalist Sharon Begley attended ICCF10 and wrote a fine column in the September 5, 2003 issue of *WSJ*, "Cold Fusion Isn't Dead, It's Withering From Scientific Neglect." Among other surprising technical developments at ICCF10 was the presentation by a well-funded Israeli corporation, Energetics Technologies, which appears to have made enormous strides in overcoming some of the problems with the low-energy nuclear reactions phenomenon. Isn't it time that the experimental data from this significant field of scientific work is reviewed by an unbiased panel, unlike the rush-to-judgment hostile group in 1989, which inexcusably botched that

investigation? Why aren't the many politicians who have been informed about this taking action? Are they perhaps fearful of the all-to-common "sneer review" from the Scientific Establishment?

Category 2. Vacuum energy, Zero Point Energy or "ZPE" for short, aether energy, or space energy. These are descriptions of vast energy sources from the vacuum state. Information about this most radical and paradigm-shattering physics and technology research can be found on websites: www.aetherometry.com, www.energyscience.co.uk, and www.aethera.org. In the mid-1990s, Dr. Paulo and Alexandra Correa in the Toronto area obtained three US patents on an astonishing technological device, the so-called Pulsed Abnormal Glow Discharge (PAGDTM) reactor. In its several embodiments, it already produces kilowatt-level electrical, thermal, and mechanical output power. A Quicktime video of one such device, working in 2003, may be viewed at www.aetherometry.com/cat-abrimedia.html. Successful testing of the PAGD by outside parties, including Israel Aircraft Industries (IAI) and Ontario Hydro, regrettably did not lead to commercial arrangements to further the development of this scientific wonder, which has been meticulously documented in the three United States-granted Correa patents. (Uri Soudak, former Chief Technology Officer of IAI, is still involved with the project here in the U.S.) The Correas and Dr. Harold Aspden, IBM's former chief of patent operations in Europe (from 1963 to 1983), have provided convincing theoretical explanations, based on concrete experiments with a variety of fundamental phenomena, all of which illuminate how this unsuspected vacuum state energy can be extracted by the PAGD reactor. The advent (possibly *in only 2-3 years)* of self-sustaining electrical power-generating units in the multi-kilowatt power range appears to be only a matter of gathering a relatively small amount of engineering/scientific development funding, in the low several tens of million dollars range.

Category 3. Environmental energy, *i.e.* energy from sensible thermal energy (in particular, energy of molecular motion), through significant extensions to the Second Law of Thermodynamics. The Proceedings of an important scientific conference dealing with this subject gives great insight into this work: *Quantum Limits to the Second Law: First International Conference on Quantum Limits to the Second Law* (San Diego, CA, July 28-31, 2002), Professor Daniel P. Sheehan, Editor, American Institute of Physics, Conference Proceedings, #643, 2002. A strong consensus of a significant number of the scientist attendees, as reported by the author, is that it will be possible to make utilitarian machines that convert the thermal energy in the environment to useful work, without a lower temperature reservoir to dump waste heat. This would be in direct contravention of the supposedly sacrosanct Second Law of Thermodynamics. These devices would be nearly perfect "free energy" machines. Accurate simulations of such devices have been carried out and the results published in peer-reviewed journals. Some of the authors predict that such prototype devices could be reduced to small prototype units within five years.

The foregoing brief descriptions of the three categories of New Energy identified so far is only the tip of the iceberg of the verifiable and testable information that is available on these energy sources. **It is amenable to critical and precise scientific review.** Of course, if the Scientific Establishment trusts only in its textbook theories and if disbelieving people of good will who have the means to move this work forward choose "not to look through the telescope," the consequences will be that these wondrous technologies will not be developed as rapidly as they could have been otherwise -- or they may not be developed at all! This has been and will be a monumental tragedy for virtually every category of human experience, all of which would be transformed by these now apparently "unwanted" discoveries.

I could write much more in this memorandum about the corrupt machinations within the supposedly well-ordered and ethical house of science, actions that have kept the information that *Infinite Energy* publishes from where it should be: prominently considered in such publications as *Science* and *Nature*. Don't worry, many, many *peer-reviewed* technical publications have indeed courageously published pioneering technical papers about new energy, but the prominent mainstream publications that set the boundaries of the public scientific discourse -- journals such as *Science* and *Nature* -- *reject without review* any and all papers that challenge the foundational paradigms of physics, chemistry, and biology. You may find that difficult to believe, as I would have a mere fifteen years ago when I wrote *Fire from Ice*, but it is a sad and demonstrable truth. Let us not dwell on that, however, but rather move forward together with an end-run around this grotesque, anti-scientific obstruction.

Infinite Energy Magazine has been published bi-monthly since March 1995 and I have been its Editor-in-Chief and Publisher since that time. It is a technical magazine with editorial outreach to the general public as well. Many of its articles are very accessible to laypeople and non-specialists. You may download *for free* some 117 pages of representative sample articles, which we have gathered together for you at www.infinite-energy.com. Other key articles

are posted for free downloading on our website on a continuing basis. To maintain the highest editorial standards, *Infinite Energy* is written and edited by scientists, engineers, and expert journalists. It is aimed at pioneering scientists, engineers, business people, environmentalists, philanthropists, and investors who are concerned about an exciting R&D area that we believe will change the world dramatically.

New Energy Foundation, Inc. (NEF) is an IRS-approved 501(c)(3) public charity corporation, based in New Hampshire; it has a five-member board of respected citizens. (Prior to July 2003, *Infinite Energy* had operated under a for-profit corporation.) NEF also has a research grant-awarding function, which was initiated in 2003. NEF dispenses to outside researchers and developers carefully targeted research and development funding grants from its reserves of charitable contributions. These funds are beginning to grow, but are nowhere near the level they need to be.

The current subscription price and newsstand price of *Infinite Energy* provides less than 30% of what it costs to carry on a publication of this quality at the frontiers of knowledge -- and for which no significant advertising base yet exists. And this frontier knowledge is neglected (and not infrequently mocked) by most of the scientific and media establishments. Therefore, charitable contributions are needed to carry on this important information networking function. Here is the other basic motivation for NEF: It has been far too difficult (so far) to persuade venture capital to invest in new energy technology that is not quite ready yet for "prime time," so the vicious Catch 22 ("We won't invest because it is not successful already.") must be broken. We appeal to the humanitarian and charitable instincts of those in a position to invest charitably in and/or to spread the word about the most fundamental aspect of our future: The triumph of truth over falsehood on the frontiers of science -- in which the new energy field, in our view, will be the first paradigm-shattering example.

What we have today in the fiery menace of hydrocarbon fuels and its associated geopolitical nightmare is very ugly indeed. There is almost no area of human activity that would not be dramatically affected by the advent of new energy technology -- especially matters of war or peace and health and the environment. Therefore, if your review of the referenced material convinces you that this is a reality and not "pathological science," as the unrepentant critics -- who *have not studied the scientific findings objectively or at all -- would* have you believe, we hope that you will view your tax-deductible support of the New Energy Foundation as a significant investment in your future, for your loved ones and for civilization at large. Just try to imagine our world twenty or fifty years hence *without* the advent of a dramatic source of new energy such as low-energy nuclear reactions, aether energy (or Zero Point Energy/space energy/vacuum energy, if you prefer), or some other very powerful new physics energy source. It is not a pleasant picture.

What about solar power, wind power, or hydrogen fuel cells, you ask? Those are fine, and *Infinite Energy* devotes some smaller space to writing about these. But a future of abundant, clean energy has almost no chance of emerging from the well-intentioned, beneficial, but extremely limited world of wind-power, photovoltaics, hydropower, and other conventional renewables. And the so-called controlled *hot fusion* tokamak reactor program, which is lavishly funded with *billions* of dollars by governments to the exclusion of *workable* new energy science and technology, will never bring about an era of clean abundant energy from the heavy hydrogen in water. Conventional hydrogen fuel cells, which are widely discussed by the news media today, rely on the conventionally understood energy from hydrogen when it combines with oxygen to form water. *This is thousands to millions of times less powerful per gram of hydrogen than already demonstrated new energy sources!* Furthermore, the hydrogen for conventional fuel cells must come from some other energy source that must be used to break down abundant *water* to get hydrogen fuel (if we reject the other hydrogen source: *hydrocarbon fuel*). But in all *conventional* hydrogen fuel processes using water as the starting material, this requires more energy than one gets back when the hydrogen is consumed. So ordinary "hydrogen power" is a misnomer at best -- it is no solution at all to the world's real energy needs. Hydrogen, conventionally employed, is *an energy storage medium* period. New Energy Foundation supports radically new forms of energy, not the relatively weak examples of alternative energy within conventional renewables. We acknowledge, of course, that there are now no robust new energy devices on the market -- not yet. But when adequate, well-targeted research funding is applied, a revolution in energy technology will occur that will dwarf the personal computer revolution in intensity. It will have much in common with that revolution too, since power sources will be highly distributed. The very troublesome and erratic power grid is doomed to obsolescence.

At this time, New Energy Foundation is in need of financial support from a broader community than heretofore. NEF disseminates information about potentially world-changing technologies -- about the science, technology, patents,

investment, and politics thereof; we measure and investigate new claims about new energy devices to determine whether they are sound. This latter can be tough, because there is no question that there is much bogus "free energy noise" that obscures the good research. Most important, we are now processing grant applications by scientists and inventors from around the world, so that the most promising work -- now highly under-funded, due to the very heretical nature of this work -- gets the financial support that it so much deserves. We are very demanding about these grants; we insist that the research must be headed in the direction of developing publishable scientific results and/or actual commercially useful technologies that operate on new scientific energy principles

Please help us today, either with your financial contribution -- of any size -- or by passing along this letter and our message to those who may be better able to help NEF. Whatever you or they can afford, no matter how small an amount, will be deeply appreciated -- and will be acknowledged in the pages of *Infinite Energy* (unless you or others tell us that anonymity is requested). Some day we will live in a world in which the discoveries of New Energy science will be taken for granted. No one will be able to deny the devices, processes, and science, whose validation we are struggling so hard to achieve. In some sense, we will then have succeeded in our mission and thus will have "put ourselves out of business." Those scientific publications and general media, which should have been dealing fairly with this topic all along, will then be forced to write about it and recant past inexcusable excessive skepticism. Billions of dollars in R&D money will then flow from corporations and individuals, *as should have been happening already based on what scientists have already discovered!* The huge funding for infrastructure conversion to New Energy will flow naturally from private sources, as it has in the rise of the personal computer and Internet industry. Nothing would make me happier than to have that day come. But until then, we very much need increased financial support.

We would like to reach soon our target of at least $500,000 per year in approved research funding for New Energy. That may not seem like a lot of money to do significant research, but let me assure you that even this amount -- wisely distributed to the best researchers -- could soon begin to have a dramatic catalytic effect. New energy researchers are accustomed to low budgets and are fantastically creative, unlike the wasteful government energy research programs that have demonstrably failed already. It will not be easy to obtain even this level of modest research funding -- and, of course, several millions of dollars per year would accomplish much more, but the sooner well-targeted funding reaches under-funded researchers, the more likely we are to accelerate the inevitable New Energy Revolution. Yes, we understand that there is room in parallel for corporate start-ups, and we definitely encourage that to take place. But some of the charitable grant money can help the struggling inventors and scientists to do sufficient research, so that their work can be of greater interest to corporate start-up models.

I think you would agree with me that in these often very dark times the world would benefit immensely from a realistic *hope -- followed* by on-market technology -- that a new era of abundant, clean energy resources will be dawning. Please do your best to help us make that happen. Study the hard-won information that we have brought to your attention, if you do not yet accept what I have tried to convey to you. When you have become convinced, if you are not already, please act! You may donate charitably to the efforts of New Energy researchers at www.infinite-energy.com. Please also help us to bring this critical issue to others who may be able to help. Why not satisfy your curiosity and also help New Energy Foundation by subscribing to *Infinite Energy*. Thank you in advance for joining with us now or in the very near future.

Sincerely,
Dr. Eugene F. Mallove
President, New Energy Foundation, Inc.

116) A negative evaluation of cold fusion claims

Ludwik Kowalski (12/9/2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Several days ago I received an e-mail message from Dr. Kirk Shanahan. Last summer he sent me a paper on calorimetry that was published three years ago. That paper (1), like several others, helped me realize that calorimetry can be very tricky. That is why I think that the most convincing arguments, either for or against cold fusion, are those based on products of nuclear reactions, not on the generation of excess heat. Excess heat, even when it is real, can be caused by non-nuclear processes. Production of neutrons, protons and heavier particles, on the other hand, can be due to nuclear transformations only. Thus, experimental findings of S. Jones et all (2), or A. Lipson et al (3), for example, are more convincing (about something unusual going on) than calorimetric arguments presented, for example, by E. Storms and M. McKubre.

But cold fusion was discovered via calorimetry and “excess heat” is still a major argument of those who expect CF to become a path toward new energy resources. That is why technical issues of calorimetry, raised by Dr. Shanahan, should not be ignored. I hope his paper (summarized below) will contribute to improvements of measurements, especially when excess heat is a small fraction of total heat generated in an experiment. Exchanges of e-mail messages between me and Dr. Shanahan, are worth preserving. That is the motivation for this item.

Kirk:
In looking over your web page(s) on cold fusion, I find no reference to my explanation of the effect. Why is that when I have sent you the paper? Did I miss it?

Ludwik:
My recollection is that your paper is mostly about calorimetry, and possible systematic errors, rather than about cold fusion. It is one of many papers that I saw but not wrote about, mostly because I did not feel competent in that area.

Kirk:
You are correct. It is about a systematic error in calorimetry, but the point is that that is why people see excess heat in cold fusion experiments. In a nutshell, the paper makes the point that a simple calibration constant shift is fully capable of explaining how Ed Storms got 'cold fusion' from a platinum electrode. (Note that Pt does NOT hydride, thus Ed's getting CF from it clearly indicates that hydriding is not the primary controlling factor in CF. This means that concerns about bulk loading of Pd are not primary.) I have looked back through all the cold fusion literature and find the same problems present throughout, right back to F&P's 1990 paper. With a few exceptions then, I claim all reports of excess heat are mismeasurements. I would say that is a pretty powerful statement that you should consider if you want to claim you know the field.

Ludwik:
Please send me a brief summary at a level appropriate for physics teachers.

Kirk:
OK... Whenever an experiment is calibrated, a descriptive equation with calibration coefficients is established. That equation is then used to 'translate' subsequent raw experimental data into results. However, the underlying assumption which must be true for this procedure to be correct is that the calibration equation must be applicable during the experimental time frame. My paper analyzes the expected results when this assumption is violated for a simple linear calibration equation in the specific case of excess power measurements. However, the problem is generic. Whenever an inappropriate calibration equation is employed, inappropriate results are obtained. Furthermore, there is no reason to expect any form of the calibration equation will avoid this problem. Simply put, if your experimental system is changing, it can't be calibrated.

In the paper, a set of data supplied by Dr. Edmund Storms which was used to suggest that Pt can produce 'cold fusion' is reanalyzed in light of the calibration constant shift problem. It is shown that _assuming_ no excess power produces run-specific calibration constants that statistically bracket the constants expected for a pure water value by about +/- 3%. In other words, it is implicitly suggested that the 'cold fusion' calorimeter is unstable to that level.

Thus, there is now a new proposition on the table regarding claims to have observed excess power from heavy water electrolysis cells. Namely, there seems to be some real physical/chemical process acting in the cells that causes an instability, reflected primarily through shifts in the calibration constants. In good science, when an apparently valid counterproposal is offered to explain experimental results, scientists are required to address the counterproposal, theoretically and experimentally if required.

Dr. Edmund Storms and I have had extensive communications where he has tried to rebut my explanation, but in my estimation he has never succeeded in debunking my proposal. Instead he proceeded to conduct further experimentation without figuring in the problem, and produced another set of data (presented at ICCF10) that still shows the same basic problem, albeit now with a quadratic calibration and resultant quadratic excess power curves. He has also shown that a highly localized application of heat via a laser to the cathode maximizes the error, which supports my basic physical/chemical mechanism for how a calibration constant shift might occur. I have commented extensively on this in the Usenet newsgroup sci.physics.fusion [s.p.f.], and many of Dr. Storms comments were posted there with his permission as well.

See messages:

<db28db991beae7a3563e830842cd9c29.38703@mygate.mailgate.org>
<13959d99bc79e6e0c054b4a3c6ed470c.38703@mygate.mailgate.org>

for a quick example of where I was discussing the issues with Jed Rothwell. You should do a Google search on my name as author in s.p.f. There are over 300 hits there, not counting all the replies, going back to 1995.

Ludwik:
I would also be interested in your overall views on cold fusion, in light of what you know now.

Kirk:
You can get lots of details on all these from my s.p.f. posting. In short:

- no excess heat, it's a calibration constant problem

- no transmutation, is failure to interpret data from surface analysis techniques adequately, combined with failure to recognize active leaching/deposition processes
- no He products - it's bad mass spectrometry (see papers by W. Brian Clarke, et al)
- no radiation detection by film - it's hypering and heat
- not enough tritium results available to decide, but interferences and contaminations are suspected (by me)

Ludwik:
Where are you now and what is your current level of commitment to cold fusion?

Kirk:
I work in the Hydrogen Technology Section of the Savannah River Technology Center of the Savannah River Site. . . I am a physical chemist who studies aging effects of tritium on metal hydrides and polymers, and who supports the tritium isotope separations processes as needed. Those processes use metal hydrides, including Pd, Ti, La-Ni-Al alloys, and many others. When researchers claim they have induced 'cold fusion' in such hydrides, they directly threaten my and my coworker's health and safety by implying that we could be unknowingly being irradiated and subjecting ourselves to a potential explosion/ radioactive material contamination from a leak arising from an unexpected heat excursion in our closed vessels that contain radioactive and flammable tritium gas.

I have been involved in hydrides since 1995, and I also began studying the cold fusion area at that time. I have concluded that it is in all probabilities not real. I have most definitely concluded that the scientists conducting CF research are sub-par, typically ignoring any information that is inconsistent with their predetermined conclusions, and generally not conducting adequate work to support their claims. On the other hand, many vocal skeptics of the cold fusion claims are likewise guilty. I try not to be, and I feel I can adequately defend my position, and have done so on Usenet and elsewhere.

OK, I've tried to hit you hard here, because I see that you are 'connected' with the CFers. I am hoping you are a good scientist and teacher, and will take the time to assess my claims, which includes discussing any issues you see with me and others. You will find the CF community considers me a 'crackpot', but I assert to you that that is an unjustified attempt to marginalize what I say. 'Crackpots' don't present well-thought-out, technically defensible proposals. I hope that you will incorporate my thinking into what you teach your students, because it seems quite a shame to miss the primary lesson of cold fusion, that it is very easy to let your desires and wants override good science.

Ludwik:
Thanks Kirk: I will think about your long e-mail message received this morning (12/9/03). It helped me to understand your paper better, I think. You provided more food for thought that can possibly be squeezed into one short item.

==========

APPENDIX

In reading statements about excess heat I saw descriptions of cases in which excess heat was much larger than Pin. Such cases would be highly convincing that excess heat is real; no refinements described by Kirk would be necessary to justify this. What I have in mind is the episode described in Muzino's book (5), or the following piece of information posted by Eugene Mallove.

"INFINITE ENERGY Magazine of Concord, New Hampshire will sponsor an all-day Cold Fusion/New Energy Symposium on January 20, 1996 at the Cambridge Marriott Hotel in Cambridge, Massachusetts. ..... One of the many high points of the gathering will be presentation of the latest findings on the Clean Energy Technologies, Inc. (CETI) Patterson Power Cell, which recently achieved record excess power production levels for a cold fusion process -- in one test greater than 1,300 watts thermal output for about 1.4 watts DC input electrical power." I met the inventor of this cell in August 2003 and asked about the event. He smiled and did not want to talk about it. Muzino wrote that he also could not reproduce the episode described in the book. The overall situation seems to be as follows:

a) Reasonably reproducible excess heat power, but very small in comparison with Pin, has been reported by many qualified researchers. But many of them do not offer enough information to rule out possibilities of experimental errors, or to rule out a possibilities that excess heat is real but not nuclear. That seems to the main point of Kirk's messages. He keeps emphasizing that "almost all reports of observed excess heat" suffer from errors in calibration.

b) Totally unconfirmed stories of very high excess heat power, even after Pin became zero, have been told. But such stories can not be taken seriously. It is OK to be motivated by anecdotal evidence but it is not OK to accept it without serious investigations.

Shanahan is not the only qualified scientist claiming that a nuclear origin of excess heat has never been demonstrated. According to Steven Jones (4): "It is high time to strongly question claims of cold fusion based on crude techniques and to demand tests at a rigorous scientific-proof level. ..... Different detectors must give signals which agree qualitatively. . . . Otherwise, the researcher may well be chasing noise, and probably making noise as well. (Hyping questionable results in the media seems to be a characteristic practice of those claiming excess heat, which we never did.) I have not seen any compelling evidence for any "cold fusion" effects, to date."

It is clear to me that the term "cold fusion" is used by Jones as a reference to any nuclear phenomenon able to produce a measurable amount of excess heat. Low level nuclear phenomena discovered by Jones (see item 113 on my list) do not generate measurable excess heat; he would probably not call them "cold fusion." Most scientists, however, would disagree; they would say that Jones' research belongs to the field of cold fusion. Fortunately, this kind of disagreement is not important.

Let me end with an additional quote from (4); it shows a dilemma faced by all cold fusion researchers. "What should a scientist do with an anomalous experimental result (one which flies in the face of prevailing theories), which is statistically significant (at the five sigma + level), yet which cannot be repeated at will? This is the problem which plagued us early on in our non-plasma or "cold" fusion experiments which began in spring 1986 at Brigham Young University, 2.5 years before we heard of the ostensibly-related work of Drs. Pons and Fleischmann. It is a question which haunts us still. I invite the reader to seriously consider the question posed above: what would you do with such data?

If you walk away from an anomalous result, you could miss something important. Indeed, is it scientifically honest to ignore such data? One can argue that scientific instruments often show "glitches," and this is probably just one of these. Quite possibly. But what if the "glitch" is not only statistically significant, but also has interesting characteristics, such as the correct energy (2.5 MeV) for neutrons from deuteron-deuteron fusion, and the expected signal-width? What if other data runs which are individually significant only at the 2-sigma level also contribute this peak? Well, what would you do? Keep trying to find the trigger mechanism, if any? How many months would you be willing to spend/waste? Would you continue if all grants dried up for this project and if virtually everyone thought the effect was non-existent and laughable?. ...."

I think that above question can be asked about any cold fusion area, including excess heat. Perhaps conditions favoring high level of excess heat will soon be identified and practical applications will become reality. For the time being, however, cold fusion researchers should study what seems to be reproducible (even if it is not yet 100% reproducible) and learn more, like in any other area. Constructive criticism of calorimetric methodology, offered by Dr. Shanahan, seems to be valid to me; I would like to know what research scientists think about it.

117) Exposing false claims

Ludwik Kowalski (12/11/2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

After posting the previous unit I felt guilty for writing about something that I did not fully understand. The main idea of Dr. Kirk Shanahan's paper is simple enough but details are not. The paper is not written for people like me; it is written for cold fusion calorimetrists. This explains why I ignored the paper when I first saw it in August. In item #116, I mostly repeated statements made by Kirk without understanding many details described in the paper. Other non-specialists might find themselves in the same situation. What follows is an essay summarizing my understanding of Kirk's views. The essay is a dialog between a student, a teacher and an engineer. The content is inspired by numerous e-mail messages received from Kirk in the last ten days; the form is inspired by Galileo Galilei.

The main point of this pedagogical exercise is to address the subject without using electrochemical terminology and concepts. I want to focus on well know aspects of error analysis, not on details which are likely to emerge in real research situations. Individual contributions are numbered to facilitate further discussion.

==========

1) Student:
My friend, an electrical engineer, discovered an unusual resistor. It behaves normally when the current is low (below 100 mA); the electric power, Pin, and the heat generation rate, Pout, are identical, as they should be. But at a larger current the Pout exceed the Pin. The engineer thinks that he has discovered a new phenomenon; some unknown exothermic process is triggered by the current in the material from which the resistor is made. Is this possible?

2) Teacher:
We do not know everything about nature; new discoveries are likely to be made anywhere and at any time. Your friend may indeed be making an important discovery but I am not willing to accept his claim on faith.

3) Student:
My friend has a calorimeter and other instruments. He said he is willing to make a demonstration. Would you be interested in seeing it?

4) Teacher:
Yes, I would.

5) Engineer (one week later):
Thanks for allowing me to use the laboratory. Everything is ready. Should we go and start collecting data?

6) Teacher:
I would prefer you to first tell us exactly what you want to do. Where is your "magic resistor?"

7) Engineer (reaching in his pocket):
Here it is. The length of this green cylinder is 7 cm and its diameter is 2 cm. Two wires are soldered to the terminals. I can lower this cylinder into water and pass an electric current through it. A thin insulating coating keeps water away from the electric circuit. I will connect this resistor to a d.c. power supply and show that V/I is essentially constant (Ohm's law), at least up to I=0.1 A. The R will be close to 160 ohms.

Next I will immerse the resistor in water and pass a current I=250 mA through it. The input power, Pin, will be calculated as V*I, where V is the measured voltage across the resistor.

8) Teacher:
How accurate are your voltmeter and ammeter?

9) Engineer:
According to manufacturer's specifications the accuracy of each instrument is 0.5%. This means that the accuracy of Pin will be 1%.

10) Teacher:
And what kind of instruments will be used to measure the Pout?

11) Engineer:
For this I have built a flow calorimeter. It is a well isolated container whose capacity is close to one liter. Water enters through the pipe at the bottom (passing through a commercial flowmeter) and exits through the pipe near the top. I will set the flow rate to about 50 cubic centimeters per minute. The temperature of entering water, T1, and the temperature of exiting water, T2, will be measured.

12) Teacher:
How accurate are the thermometers and the flowmeter?

13) Engineer:
Temperatures can be measured with an accuracy of plus or minus 0.1C. The factory-specified accuracy of the flowmeter is 1%. The container is thermally insulated; this means that practically all heat (at least 99.9%) is removed from it by water.

14) Teacher:
Your goal is to determine Pout. How will this be accomplished?

15) Engineer:
I will calculate it from the following equation: Pout=S*F*(T2-T1), where S is the known specific heat of water (4186 J/kg*C), F is the flow rate (in kg/s) and (T2-T1) is the measured difference of temperatures.

16) Teacher:
That makes sense. Will the (T2-T1) remain constant?

17) Engineer:
At the beginning T2 will be the same as T1. Then T2 will start increasing slowly while T1 will remain constant (room temperature). After about two hours T2 will stop changing and (T2-T1) will remain constant. This will indicate that in each minute heat generated and heat removed (by circulating water) are equal.

18) Teacher:
How accurate will be your determination of Pout?

18) Engineer:
The difference of temperatures will be about 10 C. Thus the accuracy of the (T2-T1) term will be slightly less than 1%. To be on the safe side I will assume it is 1%. The accuracy at which F will be measured, as I said before, will be 1%. In

other words, Pout will be known at the accuracy level of 2%.

19) Teacher (addressing students):
Let me make a comment. Our guest is using the word "accuracy;" rather than the word "precision." This is correct. The word “precision” should be used when we are referring to random errors while the word "accuracy" should be used when we are referring to systematic errors. Suppose Pout turns out to be 40 W. Then, knowing that the accuracy is 2%, we would be able to say that the "true value" of Pout can be anywhere between 39.2 and 40.8 watts. Unlike random errors, which may also be present, systematic errors can not be reduced by performing the same experiment many times to obtain the average value.

20) Engineer:
Yes, I learned about this recently. In some textbooks the terms “accuracy” and “precision” are still used interchangeably. It is easy to be confused. What else would you like to know about my apparatus?

21) Teacher:
I think we should continue discussing your data. The two numbers you provided (2% accuracy for Pout and 1% accuracy for Pin) are highly important. That is why we focused on them first. How large were the actual values of Pout and Pin?

22) Engineer:
They turned out to be 37.4 W and 36.4 W, respectively. To me it means that the difference between these two numbers, 1 W, represents the "excess power." It is the rate at which thermal energy is generated inside the calorimeter. I think that this happens through a new nuclear process. What else can it be?

23) Teacher:
I can think of many non-nuclear processes able to generate heat at the rate of 1W.
Before addressing the issue of causes, however, I would like to ask a different question. Is it possible that the difference of 1 W is nothing but an experimental error due to the limited accuracy of measurements? We know that the true value of Pout can be anywhere between 36.6 and 38.2 W. That is based on your 2% accuracy. Likewise, the true value of Pin can be anywhere between 36.0 and 36.8 W; this is based on your 1% accuracy. Thus, the difference between Pout and Pin, can be as small as -0.1 W or as large as 2.1 W. Do you understand my reservations?

24) Engineer:
I understand you very well. Instead of accepting my hypothesis (that the excess heat is real) you prefer to accept your own hypothesis (that the excess is an illusion due to ever-present systematic errors). Why should your hypothesis be taken more seriously than my hypothesis?

25) Teacher:
Because we are not in the same situation. You are claiming that something extraordinary is taking place; I am only a defender of status quo. If you are right then the Nobel Prize might be awarded to you; nothing of that kind exists to recognize my modest contribution. The burden of proof is yours, not mine. That is how science works. In our legal system the accused is presumed innocent until proven guilty; in science a radically new idea is presumed wrong until proven correct.

26) Student:
That’s what we learned in another course. A statistician starts with a “null hypothesis” stating just the opposite to what is being claimed. Then he tries to do everything reasonable to justify that hypothesis. Failure to justify the opposite constitutes the basis for acceptance.

27) Teacher:
Yes, such strategy can be used in natural sciences. But keep in mind that statistical methods have been developed to deal with random errors while we are discussing systematic errors. Statistical errors can be reduced by repeating an experiment many times, random errors can not be reduced in that way. Calibration errors are usually categorized as systematic errors. A faulty thermometer, for example, might show that the temperature of boiling water, at standard

pressure, is 110 C instead of 100 C. The strange effect (10 C of "excess temperature") will not go away when the average temperature is calculated after performing 1000 measurements.

28) Student:
But what if the effect is real? Assuming that the 10C of excess temperature is due to an error of calibration one may miss a chance of discovering something important.

29) Teacher:
Yes, such possibility does exist; the observed effect can be due to a hidden variable of some kind, for example, a cosmic event in another galaxy, or wishful thinking of a magician. Before accepting something unusual, however, a scientist should convince himself that the instrument is not faulty, for example, by measuring the temperature with other thermometers. First he would assume that the instrument is faulty then he would reject this hypothesis by showing that the instrument is not faulty. The name of the game is checking and double-checking before accepting something unusual.

30) Engineer:
So what would it take to convince you that my hypothesis is correct?

31) Teacher:
It is not just me; by announcing a radically new idea you are challenging the entire scientific community. You must do two things to be taken seriously. First repeat the experiment using more accurate instruments. What you have built would be fine if the difference between Pout and Pin were larger, for example, 10 W or more. But it is not accurate enough for your 1 W difference.

32) Engineer:
And what is the second thing that I must do for my hypothesis to be acceptable?

33) Teacher:
Once you convince yourself that the observed effect can not possibly be due to systematic errors you must clearly describe the experiment. The description, in the form of a paper, or in the form of a conference presentation, should be sufficiently detailed to allow replications of your work. You are likely to be taken seriously after your results are independently confirmed by others. The exact error analysis should be an essential part of your publication.

34) Student:
I think that claiming a discovery is more fun than defending the status quo.

35) Teacher:
That might be true. But making scientific contributions is a serious matter. Those who are engaged in it must respect established rules of acceptance. Following these rules is very different from what poets or composers do to be successful. Scientists must be objective; they should resist the temptation to have fun by making false claims. They should be guided by experimental facts and reliable theories, not by wishful thinking.

36) Engineer:
I appreciate your comments and I will try to improve the accuracy. I will borrow a more expensive flowmeter; this alone will allow me to lower the level of uncertainty by about 0.8%. I will also reduce the flow rate; this will increase (T2-T1) from about 10 degrees to about 50 degrees.

37) Student:
How will this help you?

38) Engineer:
The relative error will not change for T1 but it will be reduced for T2. The percentage error, as you probably know, is the ratio of the absolute error (0.1 C) over the value of T2. That value will be higher when the flow is reduced.

39) Teacher:
How much can you gain from making (T2-T1) larger?

40) Engineer:
Perhaps another 0.5%. In fact, I can also use more sensitive thermometers. More accurate voltmeters and ammeters are also available. Reducing the overall instrumental uncertainty from 3% to 0.3% is possible, at least in principle. Is it worth trying?

41) Teacher:
Only you can answer this question. It depends on the amount of time and money at your disposal. Personally I would first think about the so-called procedural errors. They are often responsible for unjustified claims.

42) Student:
What are procedural errors?

43) Teacher:
Procedural errors can be anything from "inexcusable blunders," such as confusing 30 with 300 (using a wrong scale) to unexpected effects of hidden variables. Let me tell you a little story. A group of students was measuring magnetic field along the axis of a wire loop positioned in the middle of a table. In doing this they discovered an unexpected asymmetry; the magnetic field on one side of the loop was different from the field on the other side. The effect was very strong and results were reproducible. The lab assistant was puzzled. It took him a while to find out that the wooden table, on which the instruments were mounted, had iron nails below the plastic cover. Procedural errors, as you can see, are systematic errors caused by hidden variables. Even experienced researchers can be victimized by such effects.

44) Engineer:
Are you telling us that experimental results can never be trusted?

45) Teacher:
Yes, a single publication is never 100% certain. But it becomes more and more trustworthy when findings are confirmed by others. In the final analysis, one may say, scientific research is a matter of consensus. I am not trying to discourage you; I am trying to make you aware of difficulties faced by scientists. Demonstrating that an effect exceeds known instrumental uncertainties is only the first step. What follows is much more difficult. The researcher should identify as many suspected hidden variables as possible and show that they are not responsible for the "new effect." The burden of proof is on the discoverer. You must convince others that the effect is not due, for example, to viscosity of flowing water, or to chemical reactions. One way to accomplish this could be to show that a common 160 ohms resistor does not generate excess heat under identical conditions.

==========

P.S. COMMENT:

1) Dr. Kirk Shanahan saw my essay and suggested that another participant, QC scientist, be allowed to participate in the debate. That "quality consciences" investigator would focus on several nontrivial aspects of scientific research. My preference is to have three participants and to keep things as simple as possible. But Kirk's suggestion to focus on hidden variables could not be ignored.

2)Kirk wrote :"Your dialog does focus on the simple concept of propagation of errors, but the point of 'QC Scientist' is that that is not what is relevant in the cold fusion excess heat case, based on my studies. He attempts to get the 3 people to realize there is more to life than just the random/systematic debate."

3) At one point I asked Kirk: "did I summarize your understanding of experimental errors correctly?" And the answer was: "You present the 'old school' paradigm. My efforts in this arena arise from the 'new school', so, you did fine on the

old school stuff, but unfortunately that's not what is relevant.” I learned a lot from Kirk’s messages and I hope he will write a good summary of ‘new school’s ideas in the next unit.

A BRIEF INTRODUCTION BY LUDWIK KOWALSKI

The previous unit (#117) was revised to incorporate valuable suggestions made by Dr. Kirk Shanahan. The most important omission of the first draft was that procedural errors were not mentioned. After posting the revised essay I asked Kirk to write closing comments on what we were discusseing for nearly two weeks. Kirk thinks that procedural errors (both systematic and random) are likely to be responsible for the apparent excess heat in all cold fusion experiments. This is very serious criticism. Unfortunately, I am in no position to comment on electrochemical errors in different kinds of calorimeters. The purpose of my essay, triggered by Kirk's published paper (see item #116), was to review the most basic concepts of traditional error analysis. As far as know, the purpose of error analysis has always been to establish the level of confidence in experimental data.

118) Error analysis; new versus old?

Kirk Shanahan (12/19/2003)

Some Comments on the 'New School' Approach to Error

In Unit 117, Dr. Kowalski appended a couple of my comments to him regarding a 'new' way of thinking about error. His units focus on the classical approach using the concepts of systematic and random error. While the scientist does need to know about the extremes of a purely systematic error and a purely random error, reality is never so cooperative as to give us the extremes. A systematic error is generally considered to be an error that produces an accuracy change. Specifically that means it is noise-free, and causes your result to be shifted away from the true value. On the other hand, a random error is usually considered to not shift the result, but to just induce noise on top of the result, which is nominally at the true value. But when the scientist walks up to her real experiment, and looks at her real results, she almost never sees anything this pure. The 'new school' of error thought focuses on the real situations, and is most often observed being applied in real world situations like process control and quality control troubleshooting.

Why should we be talking about error anyway? Because it's there, like the mountain/mountain climber case? The real reason a 'new schooler' (NSer) talks about error is because practical experience indicates it is very costly. It results in bad product being manufactured that has to be discarded or reworked, which costs money. Or it results in some cases in accidents, where people can and do get hurt. So to the NSer, anyone who doesn't define their error is economically and/or scientifically unethical. (By the way, if you're a scientist, what is your product? In the most general sense, it is information.)

So what is the fundamental difference between a NSer and an OSer (old schooler)? It seems to boil down to the attitude on what to do with error. The OSer seems to want to quantify it, and classify it (as random or systematic), but then he wants to forget it. The subtle problem with the OS approach is that it allows one to think you are done when you have quantified and classified. Isn't that what scientists do, quantify and classify their results? What else is there?

The NSer likewise quantifies error (which include propagating random error through equations by the way), but then takes a different turn. She then seeks to u*nderstand*
the error. To do that, she employs more advanced techniques than is 'usual', i.e. OS. She uses factor analysis and contour

plots and statistically designed experiments and correlation plots and... In other words, she *studies* the error. You can appreciate this tends to require a lot more work. And because of that there is a prior step I skipped, namely an economic evaluation. She asks, “OK, now that I have *this* level of error, do I need to get better (lower the total error) and can I afford to do it?” So it is the economic stakes, the presumed cost/benefit ratio, that really keys in the NSer's additional work. In the cold fusion case, the potential benefits are so high that considerable effort to understand the situation is warranted. (By the way, in this situation one 'benefit' is cost avoidance, such as avoiding injury to people. The 'cost' is the actual economic cost of doing the work proposed.)

Let's talk briefly about some rules of thumb aimed at helping one make that kind of decision. In analytical chemistry (which usually underlies most scientific research and quality manufacturing) there are some reasonably clear breakpoints in method development. It is relatively easy for an analytical chemist to 'whip out' a method with a 10% error (and by that I am being deliberately imprecise, the 10% could be either 1, 2, or 3 standard deviations, but if it is 1, the following discussion will also deal with 1, likewise if it's 3). With an approximately equal work investment, the chemist can drop the error to 2-5%. Now, *maybe* with another equal time investment, he can drop it to 1%, but it is almost as likely that it will take considerably more It is nearly impossible to get much better than a 1% technique in analytical chemistry. (Remember I am talking rules of thumb here, there are always exceptions and modifications to rules of thumb.) With purely *physics* measurements you can often do a little better, specifically it's the measurement of composition that is so difficult.

So how does this apply to the cold fusion (CF) field, specifically to calorimetry? Well, when Dr. Edmund Storms presented his paper on CF from platinum electrodes, as part of that work he showed results from two kinds of cell calibrations that were approximately 3% different. Dr. Storms is a good scientist, reasonably careful and precise, and so it is entirely expected that his presented method falls in the '2-5%' bracket. That is the 'normal' bracket one ends up in when you do good quality work on your own. It takes cooperative efforts most usually to get better than that. However, his results (and others) show an anomalous result. This is where the OS/NS difference becomes radically apparent.

In the OS approach, once the error is quantified and classified, you are done. You have basically concluded there is nothing else you can do, and that is just what the method does. So when the CF calorimeters produced an apparent excess heat signal, the simple explanation of 'instrument error' had already been eliminated. Therefore (and this is correct if there is no calorimeter error) the signal must be real, and it is large enough that it can't be a typical chemistry-based heat production, it has to be nuclear.

But the NSer says; “And where is your detailed error analysis that justifies the error-free assumption?” In other words, why should anyone accept the radical new idea of a novel nuclear process? The more common result is that there IS an error present, heretofore unknown and unnoticed. This is the 'establishment' point of view, and it was developed through long-term experience. The CFer however, wants us to agree with him that his analysis of the error situation is correct.

Since the OSer hasn't done the *study* of the error, he is unable to answer the NSer's question. So the NSer starts to work. The technical basis to the NS approach at this point is the concept that every theory (in this case I am speaking of the set of mathematical equations that are used to predict what the experiment does) is oversimplified and every experiment has thousands of hidden variables that may or may not be active at any given instant. Sounds impossible to deal with doesn't it? Thousands of variables available, and all theories inadequate to explain them. Wow, what can a researcher do? The OSer throws up his hands and says “Nothing! That's what the error IS!” And he is right on the latter point. But in fact, there are approaches that have been developed to start to address this problem, and thereby to reduce error. One key tactic from the NSer toolbox is to take a long, hard look at the implicit assumptions of the method. Back it up right to the start and ask, “Was it right to apply this that way?” or “Was it correct to assume that?” And, in order to be efficient and economical, the NSer focuses initially on any obvious difficulties (these are often called 'special causes'). In the CF case, the 3% disagreement in calibration equations was a tip-off to me.

So I did the normal NSer thing, I asked what effect the 3% error would have. Now the implicit assumption used by all CF calorimetrists to date is that their calorimeter is stable over the span of their experiments. I decided to quickly test that, so I did some algebra and derived an expression for excess power signal in the case where the 'wrong' calibration coefficients were used. What I found was that the 'theory' I developed looked A LOT like the real results. Following up further led me to a whole picture of how the apparent excess heat signal could arise from mundane chemistry and

physics, no nuclear stuff required, and then I publicized my findings. The key idea then is that by working out the impact of an observed error, I was led to a mundane explanation of how a calorimeter could indicate an enormous new heat source had suddenly appeared.

Now the next thing to happen should be to consider how we can run the experiments to differentiate whether or not my proposal is really correct. It is an unfortunate fact that whenever a hidden variable is discovered, the prior experimentation was not designed to address, i.e. record or control, that variable. Thus the prior work tends to be of no value in differentiating. It can however be used to show that the prosaic explanation works in most cases. Note that word 'most'. Remember that in a given experiment, there are 'thousands' of hidden variables theoretically available. It shouldn't be surprising then that any new factor will not fit *every* case.

So to summarize, the NS approach to error is to study it and understand it. This is versus the OS approach to quantify, classify, and forget it. The NSer cares little if the error is classified, because that tends to be an after-the-fact activity. The NSer's goal is to understand the errors and their impact, and she goes to much greater lengths to define what possible hidden variables are present.

In the CF arena, the calibration constant shift 'error' seems to be both systematic and random in nature. It is systematic in the sense that for a given datum, interpreting the datum with a shifted constant will produce a fixed offset from the true value, clearly a systematic error signature. But the actual shifts observed vary, so in that respect there is an aspect of randomness. (Actually if you examine Dr. Storms' paper carefully, you will see some clear time-dependent trends, so the shift is not strictly random.) So which is it, random or systematic? But more importantly, does that really matter? Isn't it more important to decide if the apparent excess heat signal is real or mot?

Disclaimer: The opinions expressed above are expressly those of Dr. K. Shanahan. A discerning reader should expect to find considerable objections to these opinions. Otherwise what is the point of comparing and contrasting the 'old' vs. the 'new' schools?

==========

Ludwik:
In one of my messages I asked Kirk for a reference on “the new school” ideas about errors analysis. He mentioned Deming. I asked “who is Deming?” The reply (referring to the following URL: http://www.ricoh-usa.com/about/awards/deming_the_man.asp) was:

Kirk:
Deming represents the other half of the textbooks on 'errors' that you seemingly haven't read, which isn't surprising. Most University training doesn't get into these issues at all, let alone deeply enough. It's the industrial world that lives and dies by error reduction and tighter control. A 'special cause' or 'special causal factor' is an variance-producing causal factor that typically produces 'flyer' data, and tends to be easy to identify and fix. Also, the factor tends not to be always active like typical 'random' variables. Thus, special causes tend to convert an underlying random error distribution into a non-gaussian form. Once 'special causes' have been eliminated from the error pool, the residual tends to be more nearly randomly distributed. In other words, in the process of tweaking up a chemical process or analytical method, the special causes are the first targets. The Deming Award is Japan's highest award for quality.

Deming was born on October 14, 1900 in Sioux City Iowa. After studying engineering at the University of Wyoming, he earned a Masters Degree in mathematics and physics from the University of Colorado, and was awarded a doctorate in physics from Yale in 1928. Deming developed his philosophy of using statistics to control manufacturing while working at AT&T's Hawthorne manufacturing plant in Chicago. After World War II, as the Census Bureau's chief mathematician, Deming developed sampling techniques that drastically narrowed the margin of error. He first went to Japan in 1947 to help with the country's census. The Japan Union of Scientists and Engineers (JUSE) became keenly interested in Deming's statistical methods. At the time, the Japanese product reputation was terrible. Within four years of employing Deming's methods, Japanese industry had made a complete turnaround, and was well on the road to

producing the outstanding products available today. In this country, several major organizations, including Ford, Pontiac and the U.S. Navy have thrived by implementing Deming's methods. Deming lived and worked out of a modest Washington, D.C. home. So obsessed was Deming with eliminating waste, one of his daughters recalled he dated his eggs with a felt tip pen so that the oldest would be eaten first. He conducted his intensive four-day business seminars right up until less than two weeks before his death in December 1993, at the age of 93.

119) Errors in unison ?

Ludwik Kowalski (12/20/2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

After reading final comments made by Dr. Kirk Shanahan (see Unit #118) I composed another essay, similar to that of Unit #116. The previous essay focused on systematic errors, the one shown below focuses on random errors. The main point is to illustrate Kirk's view that these two kinds of errors can not always be separated. As before, the content is inspired by numerous e-mail messages received from Kirk in the last two weeks; the form is inspired by Galileo Galilei.

==========

1) Student:
My friend, an chemical engineer, discovered an unusual radioactive rock. The radioactivity of that rock increases when the temperature goes up. Is this possible?

2) Teacher:
We do not know everything about nature; new discoveries are likely to be made anywhere and at any time. But I would be highly surprised if his claim turned out to be validated.

3) Student:
Why would you be surprised?

4)Teacher:
Because a large number of great scientists, including Marie Curie, looked for such phenomena, when radioactivity was discovered, and their results were always negative. That is one reason. The second reason is that such discovery would be in conflict with what we already know. A change in temperature, even as large as several thousand degrees, has no effect on what is going on in atomic nuclei. And radioactivity, as you know, is a nuclear phenomenon.

5) Student:
But didn't you tell us that unexpected discoveries are always possible? My friend is willing to make a demonstration. Would you be interested in seeing it?

6) Teacher:
Yes, I would. And I will try to open-minded. Keep in mind, however, that the burden of proof is on him. Most likely we will find an error in his presentation. But who knows, perhaps the claim of your friend is valid. If it is then everything we know about nuclear phenomena would have to be reexamined. Let us hear him.

7) Engineer (one week later):
Thanks for allowing me to use the laboratory. Everything is ready. Should we go and start collecting data?

8) Teacher:
I would prefer you to first tell us exactly what you want to do. Where is your “magic rock?”

9) Engineer (reaching in his pocket):
Here it is. Looks like a common stone but I will show you that it is radioactive.

10) Teacher:
What kind of counter are you going to use?

11) Engineer:
A Geiger counter, it is not very different from the one I saw in your lab. I will place this rock below the counter, set the timer, and start counting, for example, for several minutes or several hours.

12) Teacher:
Good. Why would you need to count for several hours instead of several minutes?

13) Engineer:
I count longer when I want better precision. Radioactivity is random, if if the number of counts is N then the standard deviation is the square root of N. The percentage error decreases when N becomes larger. Longer counting times result in larger N. The counting rate, equal to N divided by time, is proportional to the source activity.

14) Teacher:
That is right. Let me elaborate on this. Suppose we are trying to determine the activity C of a source with a counter when the background is not negligible. The source activity, if any, is expected to be A - B, where A is the number of counts recorded when the source is present and B is the background (when the sample is removed). If A is not very different from B, then even small random fluctuations in A and B will have strong effect on C=A-B. The standard deviation of the mean C (s3), the standard deviation of the mean A (s1) and the standard deviation of the mean B (s2) are related as:

s1^2 = s2^2 + s3^2

Suppose a single set of two measurements yields: A=100 and B=25. In that case s1=10, s2=5 and s3=sqr(s1^2+s2^2)=11.2. We would only be able to say that C is 75 plus or minus 11 (15% error). To increase the level of precision we could increase the counting time, for example, by the factor of one hundred. With A=10000 and B=2500 we would be able to say that C is 7500 plus or minus 112. (1.5% error). The longer we count the more reliable the result. Ernest Rutherford, who discovered atomic nuclei, is often quoted to say: “If experiment requires statistical analysis, then one should do a better experiment. ” He was probably referring to Geiger counter experiments in which N were too small.

15) Student:
Does it mean that any level of precision is possible?

16) Teacher:
Yes, but only “in principle.” This is an important point; I suspect that we will have to return to it later. Meanwhile let me say that your use of the term “precision” is appropriate. This term should not be confused with the term “accuracy.” Today we are talking about random errors and we identify precision with the standard deviation of the mean, s. Mathematicians do tell us the s approaches zero when N approaches infinity.

17) Engineer:
But real counters will break, sooner or later. Is that was the reason for adding the “in principal?”

18) Teacher:
Yes, this was one of the reasons. I think we are ready to hear about the actual data you collected so far. How large was your “signal”, N1, when the rock was below the counter?

19) Engineer:
It was 18043 in two hours.

20) Teacher:
How large was your background, N2, when the rock was taken away?

21) Engineer:
It was 2180 in one hour.

22) Teacher (addressing students):
In terms of counts per minute we can say that A was 150 (plus or minus 0.7%) and B was 36 (plus or minus 2%). There is no doubt that this rock is radioactive; the difference between the signal and the noise (background) is much larger than random errors. I think it is time to see the real experiment.

23) Engineer (turning toward the apparatus):
To make sure that the geometry is the same as in my earlier experiment I will place the rock on this stand. I am setting the timer for six hours. Now I am pressing the start button. Do you hear the clicks? We are not going to sit here for six hours; the counting will stop automatically and we will continue tomorrow.

24) Teacher:
May I suggest that we stop the counting in an hour. This may already reveal something significant. Meanwhile let me explain what I would like to verify. The best way to do this is to use our own counter. Let me turn it on and place our radioactive cobalt source below it. As you can see, it counts rapidly. What I want to do is to see how the counting rate depends on the high voltage applied to the Geiger tube. Please write down these results; each refers to one minute of counting.

voltage -->	700	800	1000	1100	1200	1300	1400
counts -->	0	37	372	400	458	540	974

Next plot the number of counts against the voltage. What you see is called the “plateau curve” for our counter. It shows that the dependence of the counting rate on voltage is not very strong between about 1000 and 1300 volts. That is why we normally use the counter at 1200 volts. Ideally the curve should be flat , in that way changes in voltage would not affect the counting rate. But no counter is ideal, some counters are better than others in that respect. They also differ in terms of stability of the voltage. Ideally a voltage should remain constant but in reality it changes unpredictably.

25) Engineer:
My counter stopped counting. It displays 11707. In terms of counts per minute it is 195 (plus or minus 0.92%).

26) Teacher:
This is this not consistent with 150 (plus or minus 0.7%) that you reported before? The difference between 195 and 150 is highly significant. Would you say that bringing the rock into this room changed its radioactivity?

27) Engineer:
I think that the background in this room is higher than in my basement.

25) Teacher(after the background was measured):
As you can see the background in this room is nearly one half of it was in your basement. What else might be responsible for the discrepancy?

26) Engineer:
I do not know. What do you think?

27) Teacher:
One possibility is that the plateau curve of your counter is not much better than the curve of our counter and that the

voltage applied is not stable. Suppose the voltage drifted from 1200 to 1400 volts. Have you tested stability of your power supply?

28) Engineer:
No I haven't. I simply assumed that the voltage does not drift too much.

29) Teacher:
That is a good assumption when things seem to be normal. But you are claiming something totally new and unexpected. You should check and double-check everything. One thing I would recommend, besides measuring voltage continuously, is to determine the plateau curve before and after each serious measurement.

30) Engineer:
Thanks for constructive criticism; I agree with you. I will start another sequence of experiments.

31) Teacher:
That is good; let us know what happens. Let me use this occasion to comment on the term "in principle," used above. Mathematically it is correct to say that random errors can be reduced by as much as we want. It is only a matter of making a larger and larger number of measurements and calculating averages. This,however, is true only when systematic and procedural errors are absent. But hidden variables, such as the unknown voltage instability, should always be suspected. In your case trying to improve precision by increasing the numbers of counts would be counterproductive. It does not make sense to be preoccupied with tiny cracks in one window when another window, in the same room, is widely open. Likewise, using highly accurate ammeters or voltmeters is likely to be counterproductive in an environment dominated by random errors and by effects of hidden variables. In other words, as often emphasized by Kirk Shanahan, the issues of accuracy (systematic and procedural errors) and the issues of precision (random errors) can not always be separated.

120) Deuterium gas in Palladium

Ludwik Kowalski (12/22/2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

A paper published by Chinese Sciences (Xing Zhong Li et al, in J. Phys, D: Appl.Phys. 36 p 3095 to 3097, 2003) describes an experiment in which excess heat was generated when deuterium was diffusing through palladium. I heard about similar result from an American cold fusion researcher, Glen Schmidt from Albuquerque. I visited Glen's metallurgical laboratory in October 2003 and spent several hours with him. His apparatus was very impressive. My plans of working with Glen did not materialize but he sent me several messages describing the results. My question, at the the time was: "can the excess heat be due to the Joule-Thomson effect?" Professor Li also asked this question at the end of the article. And he answered it negatively, at least for his high pressure and high temperature system.

The Chinese measurements were performed by a calorimeter able to detect heat generation rates as low as one microwatt. It is hard to make sense of what is displayed in Figure 2 without knowing the details. Why was the heating power nearly zero when the temperature was higher than 150 degrees? The heating rate, at the level of about 1 mW, was sustained for about 1.5 hours; it became zero when the temperature of the vessel decreased to 140 degrees. The issue of possible systematic, random and procedural errors was not addressed in the short article. Influenced by Kirk Shanahan (see units #116 to #119) I was looking for a discussion of errors. Why not a single word was written about the calorimeter calibration? I also noticed that the phrase "cold fusion" was not mentioned neither in the article nor in the list of references. I suppose that this was done to make sure that the article is not rejected. The main point of the publication was the correlation between the flow rate of deuterium and the excess power attributed to an unspecified exothermic process. The title of the article, "Correlation between abnormal deuterium flux and heat flow in a D/Pd system," emphasizes this point.

The library at http://www.lenr-canr.org contains 22 papers authored by Dr. Li, including the paper he presented at the 10th International Cold Fusion Conference. Dr. Li is a veteran of cold fusion research. His conference paper begins with this summary: "Great progress has been made after 14 year of experiments with the gas-loading D/Pd system. 6 watts of "excess heat" were generated in a gas-loaded D/Pd system for 9 hours continuously. This experiment has been repeated 6 times already in various configurations. The "excess power" density in the Pd disk is more than 100 W per cubic centimeter, which is about the power density in a fuel rod of a thermal neutron fission reactor."

The best argument, as far as I can determine, that the observed effect is real is a demonstration that heat generated in palladium is much higher than heat generated in copper, under identical conditions. Unlike palladium, copper does not allow hydrogen to diffuse through it and no excess heat is generated in copper. This observation should rule out many parasitic effects, such calibration shift etc. At the end of his paper Dr. Li thanks Glenn Schmidt for fruitful cooperation. Another very convincing fact (see figure 6) was that the excess heat generation rate was comparable to the rate at which heat was supplied to keep the membrane hot. In other words the difference between the Pout and Pin was no longer a very small fraction of Pin, as in electrochemical experiments. In the middle of the run, for example, Pin was 25 W while the excess power was 7 W. In the last hour of the run the percentage of the excess heating power over the Pin was close to 50%. This is much higher than 3%, reported by E. Storms, and criticized by Kirk Shanahan (see my units #116, and #118).

At the very beginning of his cold fusion conference presentation Dr. Li said that gas loading of Pd has four advantages: "safety, sensitivity, low cost, and a higher operating temperature." Four advantages with respect of what? Most likely with respect to electrochemical loading practiced by most cold fusion researchers. I do not know why the higher

percentage of excess heat is not listed as one of the advantages. And once again I see that the phrase “cold fusion” is not even mentioned in the body of his paper. Dr. Li is certainly familiar with Karabut’s work in which deuterium gas was used induce a large number of effects, including excess heat generated at the level of 10%. Why is Karabut’s work not even mentioned? Why nothing is said about attempts to observed at least some of the effects reported by Karabut? It is hard to believe that attempts to observe such effects were not made by Dr. Li, or by some of his associates. Why don’t they say anything about this? I am sorry that I did not ask this question at the conference.

121) From Wall Street Journal

Ludwik Kowalski (12/26/2003)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

While searching the Internet for something else I found an article about the current cold fusion situation. Written by **S. Begley** (shortly after the last cold fusion conference ended), the article was published in the Wall Street Journal (Sept. 5, 2003, page B1). The title was: "**Cold Fusion Isn't Dead, It's Just Withering from Scientific Neglect**." I think that the article is worth showing on this web site. Sharon Begley wrote:

= = = = = = = = = = =

"Well, were here, " said physicist Peter Hagelstein to the 150 scientists at the 10th International Conference on Cold Fusion in Cambridge, Mass., last week. "Many people in the scientific community feel we should be shot." That, actually would be a big step up for the beleaguered community of cold fusioneers. It has been 14 years since two little-known electrochemists announced, at the infamous news conference on March 23, 1989, what sounded like the biggest physics breakthrough since Enrico Fermi produced a nuclear chain reaction on a squash court in Chicago. Using a tabletop setup, Stanley Pons and Martin Fleischmann, of the University of Utah, said they had induced deuterium nuclei to fuse inside metal electrodes, producing measurable quantities of heat. (Deuterium, aka heavy hydrogen, has one proton and one neutron in its nucleus.)

Although nuclear fusion is supposed to be impossible at temperatures much below those in the sun or a hydrogen bomb, the Utah duo said they had managed the feat at room temperature. That was the opening bell for one of the craziest periods in science. Cold fusion, if real, promised to solve the world's energy problems forever. (There is enough deuterium in sea water to provide electricity for millennia). Scientists around the world dropped what they were doing to try to replicate the astounding claim. Some did, most didn't. When a US Department of Energy investigation concluded in November 1989 that cold fusion was a mirage born of bungled measurements and wishful thinking, the field become a pariah.

Yet the cold fusioneers persist. In paper after paper last week, scientists reported that when a metal, usually palladium, absorbs huge amounts of deuterium into its atomic lattice, the result is more heat than plain old electrochemistry can explain, as well as particles thought to be by-products of nuclear fusion. Some of the most extensive work has been at the Naval REsearch Laboratory, whose scientists found both excess heat and a telltale sign of fusion, particles of helium-4, in dozens of experiments. And Michael McKubre of SRI International, Menlo Park, Calif., is still, after hundreds of thousands of experiment-hours and $4 million, getting more heat from his cold-fusion cells than can be explained conventionally.

Some of the most intriguing research is by physicist Steven Jones of Brigham Young University, Provo, Utah. Several years before Prof. Pons and Prof. Fleischmann, he reported low-temperature nuclear fusion, but virtually no excess heat. That made his cold fusion a big fizzle as an energy source, but much more acceptable to science. ":The question I get more than any other is 'Are you still doing this?," says Prof. Jones. "The answer is yes, and what we are seeing is very difficult to explain outside of cold fusion. The repeatability of these experiments now approaches 80%." Although he still detects no excess heat, the telltale signs of nuclear fusion "make us conclude that we are seeing new physics."

Although the persistence of the cold fusioneers makes skeptics shake their heads, proponents see it differently. "If there

were no effects and it were just experimental error," says Prof. Hagelstein, associate professor of electrical engineering and computer science at the Massachusetts Institute of Technology, "we should have figured out that by now I don't think there is any doubt about the existence of nuclear anomalies. Excess heat might be real, too." Right about here, I would cite physicists explaining why Prof. Hagelstein is wrong. But I can't. Almost no scientist outside the ostracized community listens to its claims anymore, much less critiques them. It has been years since a major physics journal published a paper on cold fusion. Prof. Hagelstein invited some of the original critics to last week's meeting; none showed.

Cold fusion today is a prime example of pathological science, but not because its adherents are delusional. Yes, it's disconcerting that many of the experiments inexplicably and unpredictably stop (and start) producing heat. But the real pathology is the breakdown of the normal channels of scientific communication, with no scientists outside the tight-knit cold-fusion tribe bothering to scrutinize its claims. "If you 'know' that cold fusion is impossible, then you don't have to pay attention to these results," says Prof. Hagelstein, an award-winning DOE physicist before being ostracized for his work in the theory of cold fusion. "The initial criticism was that people needed to do the [heat measurements] right, but now that some groups have spent millions of dollars doing just that, the critics still won't read the papers."

I, for one, would love to hear smart physicists explain why the excess heat from the deuterium-filled palladium reflects not nuclear fusion bu t the release of mechanical energy - sort of like letting go of a stretched spring. I'd love to see a smart critique of a 2002 paper by Japanese scientists, published in a Japanese physics journal that few American scientists see, describing (shades of medieval alchemists) the transmutation of elements through cold fusion. What these claims need is critical scrutiny by skeptics. That's how science normally functions. But in cold fusion, it isn't. And that's the worst pathology of all.

122) New cold fusion data from Russia

Ludwik Kowalski (12/29/03)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Last summer Karabut wrote to me that visa difficulties prevented him from participation in the 10th cold fusion conference. But his three papers were submitted and I downloaded them from the http://www.lenr-canr.org web site. I will refer (1) to these papers as KK1 (Karabut and Kolomeychenko), K2 (Karabut) and K3 (Karabut). The papers report experimental results obtained by using the glow discharge chamber already described in my Unit #13. But conditions of the discharge, and auxiliary equipment, were different in each experiment.

The KK3 paper focuses on emission of soft X-rays (1.3 to 1.8 keV) emitted from various cathodes (from Al to Pb) of the glow discharge tube (deuterium and hydrogen gas at the pressure of 10 torrs). Two kinds of X-rays were identified: coherent (laser-like) and not coherent (diffused). The authors observe that "the emission of the X-ray laser beams occurred" both during the discharge (current pulses of 100 mA) and after the current was off. They add that "the obtained results were the direct experimental proof of existing excited metastable energy levels with energy of 1.2 - 5.0 keV in the solid state cathode samples." The authors report that in some cases the intensity of emission was as high as 0.01 Gy/s (1 rad/s).

The K2 paper reports on X-rays generated in experiments in which the current pulses were as high as 500 mA. Four different gasses (H2, D2, Kr and Xe) were used as well as cathodes made from various materials (from Al to W and Pt). Some ionizing radiation, according to Karabut, was able to penetrate the walls of the chamber (5 mm of steel). He refers to it as "secondary radiation." The abstract of the paper ends with the following sentence: "It was shown that the secondary radiation consisted of fast electrons." How are these findings related to cold fusion? I do not know how to answer this question. Is it possible that laser-like X-rays are emitted in all cold fusion experiments but nobody noticed them before? I remember Alexander telling me about laser-like X-rays in Albuquerque (in October of 2002). But I was not ready to ask questions and was very skeptical.

The K3 paper also refers to emission of X-rays but the main emphasis is generation of excess heat and detection of transmutation products. The abstract of that paper ends with the following sentence: "The possible mechanism of producing the excess heat power and products of nuclear transmutation reactions in the solid medium with excited energy levels was considered." The most significant aspect of K3 paper, as far as I am concerned, is confirmation of experimental findings that were reported in the previous cold fusion conference (see item 13 on my web site). In one case the excess power was 8 W while the input power was 14 W. In most cases, however, the excess power was about 3 W while the input power was about 9 W. These results were obtained by using the flow calorimeter. In reading K3, Kirk Shanahan (see item #115 and #118), would probably say that not enough information was provided to validate the claimed excess heat.

The section devoted to products of transmutation reactions (where the term "impurities" is used by Karabut instead of the term "trace elements") seems to be a repetiton of what has been reported by him (see item #13 on my web site). Karabut lists 20 nuclides (from ^{7}Li to ^{115}In) which are produced at the rate of up to 10^{13} atoms per second.

Titles of three articles:

KK1- A.B. Karabut and S.A. Kolomeychenko: "Experimental Research into Characteristics of X-ray Emission from Solid-state Cathode Medium of High-current Glow Discharge."

K2 -- A.B. Karabut, “Experimental Research Into Secondary Penetrating Radiation When Interacting X-ray Beams of Solid Laser with Various Materials Targets.”Emission from Solid-state Cathode Medium Of High-current Glow Discharge.”

K3 -- A.B. Karabut, “ Production Of excess Heat, Impurity Elements And Unnatural Isotopic ratios Formed At Excited Long-Lived Atomic Levels With Energy Of More Than 1 keV In A Solid Cathode Medium During High Current Glow Discharge.”

123 This is real alchemy

Ludwik Kowalski (1/24/2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Attempts to change one chemical element into another are usually referred to as alchemy. Such transformations are said to be impossible unless nuclear reactions are involved. A nuclear fusion of two deuterons ($^2H + ^2H$), for example, nearly always results in production of either ^3He or ^3H. Very rarely, once in a million fusion events, the reaction results in the production of common helium, ^4He. Turning atoms of one element into atoms of another element, such as ^2H-->^3He, by means of nuclear reactions, is usually called transmutation. Atomic nuclei repel each other and for that reason they do not fuse spontaneously at temperatures below tens of millions of degrees.

Accumulation of ^4He, and other atoms, in the electrodes of cold fusion cells, were first reported in 1991 by J. Bockris (1). Here is an interesting quote from this fascinating reference. At first, " the proposition that one could carry out nuclear reactions with metals in solids in the cold ('Alchemy') would have received unhesitating rejection and ridicule. Now, eight years later, not only are scientific papers describing such phenomena available from many groups; but scientific meetings in Russia, formerly entitled Cold Fusion, have been changed to meetings on 'Transmutation'. The American Nuclear Society has hosted sessions on Low Temperature Nuclear Reactions for three years in succession."

Progressive accumulation of ^4He was soon confirmed by other investigators (2,3) but confirmation of production of heavier elements had to wait a little longer. Facing the irreproducibility of results Bockris wrote (4): "And indeed, in very small quantities, around 100 parts per million, we got four consecutive experiments which did give -- seemed to give, to all intents and purposes -- the transmutation of small amounts of lead and mercury into gold, ruthenium, osmium, etcetera. However, when we went on with this, later, we couldn't reproduce it, so we had to withdraw. But I'm fully convinced that in the four experiments that we made we were producing these small amounts. Since then, numerous people have done similar things, but usually with other metals."

Results from extensive quantitative studies of heavy products, summarized in (5), are consistent with what has been reported by other investigators (6,7,8). The most recent report in this area was presented by Iwamura, from Advanced Technology Research Center, Mitsubishi Heavy Industries, Ltd., in Japan. Addressing the 10th international CF conference (August 2003) Iwamura described a fascinating setup (9) in which cesium is turned into praseodymium and strontium is turned into molybdenum. The paper describing these experiments (10) has already been published in the prestigious Japanese Journal of Applied Physics (JJAP). Was I the only one whose first reaction, during Iwamura's conference presentation, was to think about pseudo-scientists?

Imagine a 0.1 mm membrane, mostly Pd, separating a container filled with deuterium gas from a vacuum chamber. The gas diffuses slowly through the membrane into the vacuum; there is nothing unusual in this. The surface at which the gas enters the membrane is covered with a material to be transmuted (deposited either electrolytically or by the ion injection method). Using highly sophisticated analytical tools the researchers were able to show that the amount of targeted material, such as purified Cs or Sr, decreases, while the amount of new material, such as Pr and Mo, increases at the same rate. Comparing this situation with a typical nuclear reaction setup (a target and a beam from an accelerator) the authors write: "Analysis of the depth profile of Pr indicated that a very thin surface region up to 100 angstroms was the active transmutation zone. Many experimental results showed that the quantity of Pr was proportional to the deuterium flux through the Pd complex. The cross section of transmutation of Cs into Pr can be roughly estimated at 1 barn if we consider the deuterium flux as an ultra-low-energy deuteron beam."

The view of the membrane in Figure 1 (of their paper), shows that it is essentially a 0.1 mm Pd foil coated with several alternating thin layers of CaO and Pd. The first layer seen by the D atoms, as they enter the membrane, consists of Pd; it is 400 A thin. Cs or Sr were deposited on that layer. As indicated in another figure, it took nearly 100 hours to turn all atoms of Cs (about $1.3*10^{15}$) into atoms of Pr; transformation of an equal amount of Sr into Mo took about 300 hours. The Cs --> Pr experiment was repeated two times while the Sr --> Mo experiment was performed three times; the results were reasonably reproducible. I find it highly significant that the isotopic composition of Mo, produced from Sr, is drastically different from that found in nature. This seems to rule out the possibility of contamination (redistribution of impurities).

Low energy transmutations in condensed matter, reported by Iwamura, have recently been confirmed by scientists from Osaka University (11). Here is a quote from their brief description: "As a result, we confirmed that the nuclear transmutation reaction, from ^{133}Cs to ^{141}Pr, occurred. This transmutation suggests that the mass number and the atomic number increase by 8 and 4, respectively. . . The model of multi-body resonance fusion of deuterons, proposed by A. Takahashi, can explain this mass-8-and-charge-4-increased transmutation, as follows:

(Primary reaction) : $8D \rightarrow {}^{16}O^* \rightarrow {}^{8}Be^* + {}^{8}Be^* + 95.2$ (MeV)

(Secondary reaction) : $^{133}Cs + {}^{8}Be$ (47.6 MeV) $\rightarrow {}^{141}Pr^*$ (50.47 MeV)

or $^{8}Be^* \rightarrow {}^{4}He + {}^{4}He$

If the phenomena occur according to this model then ^{4}He should also be produced. So we are trying to detect ^{4}He."

It is interesting that radioactive byproducts of presumed nuclear reactions are not mentioned in (5) or in (9). Most radioactive byproducts would be much easier to identify, in small quantities, than their stable counterparts. Their absence seems to indicate that nuclear reactions in condensed matter (presumably responsible for the reported alchemy events), are totally different from common nuclear reactions. This has already been recognized by those who investigated generation of helium. They reported that helium generated via cold fusion is mainly ^{4}He; the ^{3}H and ^{3}He atoms are produced much less frequently. The situation is dramatically different from what happens in thermonuclear reactions taking place in gasses. In these reactions the probability of the $^{2}D+{}^{2}D \rightarrow {}^{4}He$ (releasing about 24 MeV of energy) is 10^{-6} while the probabilities of reactions producing ^{3}H and ^{3}He (releasing about 3 MeV of energy) are roughly 0.5 each. How can this difference be explained? That is one of the many theoretical questions still to be answered. At present the main issue is experimental rather than theoretical. Do occasional nuclear reactions happen spontaneously in condensed matter at ordinary temperatures or not? That question, formulated thirteen years ago, must be re-addressed in the context of new information.

Appendix:
After posting the above I wanted to see if comments about the work of Japanese scientists can be found on the Internet. And I discovered, with pleasure, that the upcoming meeting of American Physical Society (APS March, 2004) has a session devoted to "dd-Fusion-Iwamura Connection." Fortunately, the free speech policy is in effect, as far as APS conferences are concerned. I wish the policy would apply to publications in leading scientific journals; publications should not be rejected on the basis of their associations with a particular field. (Is it true that editors of APS journals tend to select reviewers of cold fusion papers from pools of scientists who are known to be prejudiced against the field?)

What follows are three abstracts of papers to be presented at the meeting. I do not understand them fully because I am not a theoretical physicist. The abstracts show that some theoretical physicists are trying to understand cold fusion. Several additional CF-related abstracts can be seen at:

http://www.eps.org/aps/meet/MAR03/baps/abs/S9530.html

==========

1) Talbot Chubb *(Research Systems, Inc. , 5023 N. 38th St., Arlington, VA 22207)*

My conjecture: LENR dd fusion occurs in PdD_x when a subset of the interstitial deuterons occupy tetrahedral sites in a PdD_x crystallite. The tetrahedral deuterons(d's), which occupy shallow potential wells, behave as a superfluid, similar to ultracold Na atoms in shallow-well optical traps, as modeled by Jaksch et al.(D. Jaksch, et al, Phys. Rev. Lett., 81, 3108 (1998).) The tetrahedral d's form a deuteron (d) subsystem, which is neutralized by an electron subsystem containing an equal number of electrons. In the superfluid all the properties of each quasiparticle d are partitioned among N_{site} equivalent sites. The partitioning of the d point charge reduces the Coulomb self-repulsion within each quasiparticle pair, which causes wave function overlap at large N_{site} , allowing d-d fusion. Similarly, partitioning of the point charge of each single quasiparticle d reduces the Coulomb repulsion between it and an obstructing impurity atom, which causes wave function overlap between quasiparticle and atom at large N_{site}, allowing transmutation of the impurity atom. The Iwamura reaction (Y. Iwamura, et al, Japan J. of Appl. Physics, 41A, 4642 (2002).) is $4\,^2D^+_{bloch} + 4e^-_{bloch} + {}^{131}Cs \rightarrow {}^{141}Pr$, with the reaction energy incoherently transferred to the lattice.

The entire paper (the “ChubbTAtheddcolf.pdf” file) can be downloaded from the Internet (see reference 1 above).

2) Scott Chubb *(Research Systems, Inc. , 9822 Pebble Weigh Ct., Burke, VA 22015-3378)*

Three, Key, Unanswered Questions posed by LENR's are: 1. How do we explain the lack of high energy particles (HEP's)? 2. Can we understand and prioritize the way coupling can occur between nuclear- and atomic- lengthscales, and 3. What are the roles of Surface-Like (SL), as opposed to Bulk-Like (BL), processes in triggering nuclear phenomena. One important source of confusion associated with each of these questions is the common perception that the quantum mechanical phases of different particles are not correlated with each other. When the momenta p of interacting particles is large, and reactions occur rapidly (between HEP's, for example), this is a valid assumption. But when the relative difference in p becomes vanishingly small, between one charge, and many others, as a result of implicit electromagnetic coupling, each charge can share a common phase, relative to the others, modulo 2n\pi, where n is an integer, even when outside forces are introduced. The associated forms of broken gauge symmetry, distinguish BL from SL phenomena, at room temperature, also explain super- and normal- conductivity in solids, and can be used to address the Three, Key, Unanswered Questions posed by LENR's.

3) Peter L. Hagelstein *(Research Laboratory of Electronics, Massachusetts Institute of Technology, Cambridge, MA 02139)*

We have proposed that phonon exchange can occur in the presence of a highly excited optical phonon mode during a dd-fusion reaction. We have also suggested (P. L. Hagelstein, Bull. APS 45, 235 (2000)) at new second-order site-other-site reactions can occur when the energy of a fusion reaction is transferred elsewhere. Fast particle ejecta from the experiments of Chambers(G. P. Chambers, et al, J. Fusion Energy, Vol. 9, p. 281 (1990).) and of Cecil (F. E. Cecil, et al, AIP Conf. Proc. Vol. 228, p. 383 (1990).) appear to be consistent with such a mechanism, in which a dd-fusion reaction at one site is coupled to a disintegration at another site. The dominant process of this type is the null reaction in which dd-fusion is coupled to He-4 dissociation. This process can lead to compact dd-states(P. L. Hagelstein, Bull. APS 2001), and is consistent with the Kasagi experiment(J. Kasagi et al, J. Phys. Soc. Japan 64, 777 (1995).). We find that compact states near resonance with the molecular D2 states changes the radial wavefunction at small r.

==========

In browsing the Internet I also found an earlier paper of Iwamura at all. Presented at the 7th International Cold Fusion Conference (Canada, 1998), it shows the history of the project. The authors wrote:

“Abstract
A new type of experimental apparatus is developed to induce nuclear reactions by continuous diffusion of deuterium. Ti atoms, which cannot be explained by contamination, were detected on the surface where deuterium atoms passed through on Pd cathodes after electrolysis. A multi-layer cathode (Pd/CaO/Pd) is introduced based on an EINR (Electron Induced Nuclear Reaction) model. Excess heat generations and x-ray emissions were observed for all the cases we tried

by the multi-layer cathodes. 57Fe/56Fe ratio of Fe atoms detected on the multi-layer cathodes is anomalously larger than natural
$^{57}Fe/^{56}Fe$.

1. Introduction
Beginning in 1993, we have researched "cold fusion" phenomena to investigate it as a potential new energy source. At first, we performed gas-loading experiments and suggested that the high diffusion velocity of deuterium, in addition to a high D/Pd ratio, is an important factor for causing nuclear reactions in solids (1)-(3) The authors analyzed electrolyzed Pd samples by a variety of methods (4), and we conjectured that impurities in Pd play essential roles to induce nuclear reactions. The foregoing ideas result in the assumption that necessary conditions to induce nuclear reactions in solids are as follows:

(i) high D/Pd
(ii) enough diffusion flux of deuterium
(iii) the existence of a third element except Pd and deuterium.

A new type of experimental apparatus was developed to induce continuous diffusion under high D/Pd conditions, in which the conditions (i) and (ii) were satisfied. (5) A multi-layer cathode composed of a Pd sheet, Pd and CaO complex layer, and Pd thin layer is developed to meet the condition (iii). Ca is introduced into Pd cathode based on an Electron-Induced Nuclear Reaction (EINR) mode (6). In this paper, experimental results using the continuous diffusion apparatus with both a normal Pd sample and the multi-layer cathodes is described**."**

The draft of the article, whose title is shown below, was posted here on February 27, 2004. The "clickable list of items" (my index.html file) referred to it as:

125) An article I want to publish (WORK IN PROGRESS)

I was still improving the draft. Then I decided to publish the article. But journals usually insist on receiving manuscripts which have not already been publish elswhere. For that reason I decided not to make my article accessible over the Internet. Attempts to publish failed and today (6/28/04) the article is going to be posted as item #152 on my web site. The item has has only three sentences below the title; it is a record for my chronologically evolving sequence. Today I will start writing the histiory of rejections. It will be a separate item showing my correspondence with editors of several journals. Each of them decided not to publish my article without telling me what is wrong with it. I think the article is an unbiased review of the main cold fusion claims. Why was it rejected? Why was it not sent to be peer reviewed?

Recent cold fusion claims: are they valid?

Ludwik Kowalski
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

What is Cold Fusion?
Cold fusion (CF) is a mixture of several claims that may or may not be related. Some of them belong to the realm of basic science while others belong to the area of patents. And some seem to be science fiction. . . .

126) Reactions or contamination, that is the question.

Ludwik Kowalski (1/24/2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

In an earlier unit I provided a brief description of sophisticated tools often used by those who demonstrate cold fusion alchemy. Except for a mass spectrometer, used to demonstrate changes in isotopic compositions, my familiarity with these tools is very limited. They are mostly used by chemists and material scientists. In this unit I want to describe another method, called "nuclear activation analysis" (NAA), with which I am very familiar. I will do this before describing an interesting paper of an American researcher, T. O. Passell. The author concludes, by using the NAA method, that the isotopic composition of palladium powder, after it was used to generate a lot of excess heat, is not the same as it was before the powder was exposed to deuterium. He also argues that nuclear reactions other than D+D fusion might be significant contributors to excess heat.

Nuclear activation analysis
Suppose you want to verify a claim that a very small amount of gold, for example, 0.0001% of the total mass of a 5 grams coin consists of gold. The NAA method seems to be ideal to show that 5 micrograms of gold (plus or minus 0.1 or so, depending on specific limitations) is indeed present. As a preliminary step you exposed a pure gold sample to a flux of neutrons for certain amount of time. The sample becomes gamma-radioactive and you use a gamma ray spectrometer to see the characteristic peak. That is your preliminary calibration. Knowing the number of counts under the peak and the mass of the pure gold sample you can calculate what to expect, under identical irradiation conditions, from the same amount of gold in the coin. If the characteristic obtained from the coin is, for example, ten times weaker than from the calibration sample then you know that the coin contains only 0.5 micrograms of gold.

I am skipping many details that become important when the issues of the accuracy (absolute error) and precision (random error) is addressed. The important point is that, gold is a monoisotopic element and the amount of ^{197}Au is essentially the same as the total amount of that substance. Many chemical elements are mixtures of several isotopes; the relative amount of each isotope in a mixture is a well known number. That number does not change by more than a fraction of a percent when samples of different origin are compared. The isotopic composition of Pd, for example, no matter where it was found on earth, is approximately as follows:

^{102}Pd 0.96%
^{104}Pd 10.97%
^{105}Pd 22.23%
^{106}Pd 27.33%
^{108}Pd 26.71%
^{110}Pd 11.81%

Deviations from the above average percentages do exist but they are, most often, at the level of very small fractions of one percent. It turns out that some isotopes are much easier to identify, by the NAA method, than others. Unlike traditional mass spectroscopy, the NAA method is not universal, it is suitable for some isotopes and much less suitable for others. In many cases the NAA is much more sensitive (allows to determin smaller quantities) than mass spectroscopy. The interesting thing about isotopic compositions is that they are essentially the same in all minerals containing that metal, for example, in rocks from Australia, Brazil, China or Denmark. It is also the same in palladium extracted from see water or found lunar rocks. In natural palladium the number of atoms of ^{108}Pd over the number of

atoms of ^{110}Pd, for example, is always 0.442. But that ration is very different in palladium extracted, for example, from spent fuel of a nuclear reactor. Passell analyzed palladium after it was used in a cold fusion experiment. The atomic ratio, ^{108}Pd/^{110}Pd, in that palladium, turned out to be 0.477 instead of 0.442. That is a very convincing indication that some kind of nuclear reactions did occur during the experiment.

Passell's two reports

Thomas O. Passell is research-oriented scientist (Ph.D. from the University of California at Berkeley) whose most recent report has been presented at the 10th International Cold Fusion Conference, (August, 2003). That report can be downloaded from <http://www.lenr-canr.org/iccf10/iccf10.htm> His older report (8th International Conference on Cold Fusion, Italy, 2000).is also worth reading; it can be downloaded from the library at <http://www.lenr-canr.org>.

In the older report one reads that "samples of particulate Pd weighing from 5 to 16 milligrams each were sent to the University of Texas for NAA.(7). All elements susceptible to NAA at a flux of 10^{12} n/cm^2-sec under an irradiation of 3 hours were detected by means of their emitted gamma rays as detected in an intrinsic germanium crystal operated at 77°K." So much for the general methodology. The neutron flux and the irradiation time are variables which could optimized for specific isotopes.

The purpose was to study chemical composition of trace elements, not to study their isotopic compositions, as in the most recent report. This is reflected in the title of the older report: "Trace elements added to palladium by exposure to gaseous deuterium." Here is how the motivation was described by the authors of this paper. "To confirm or refute the suspicion of a possible nuclear reaction producing the excess heat, trace element changes were measured in particulate Pd exposed to very high deuterium pressures generated in the hollow core of cylindrical Pd cathodes in a series of experiments by Arata and Zhang.(l) Independently in a completely different type of experiment, Mo, Cai, Wang, Wang, and Li reported observations of increased zinc for Pd exposed to hydrogen and deuterium gas.(6) In addition they reported observing an altered ratio of Zn-64 to Zn-68 relative to that of naturally occurring zinc. They speculated that the extra zinc observed may have been produced by some nuclear process induced by the hydrogen or deuterium on the Pd metal surface, since it was unlikely that contamination by handling or experimental processes would have given zinc with an altered relative abundance of Zn-64 and Zn-68."

The authors obtained three samples of palladium powder used by Arata and Zhang to generate excess heat [see item #23 on my CF site] plus one sample removed from the powder before it was inserted into the cold fusion apparatus. The chemical compositions of the first three samples were then compared with the composition of the fourth (virgin) sample. Increases in the amount of some elements, including iridium, gold and zinc, have been observed. Before jumping to a conclusion that the elements are produced through nuclear reactions, the authors write: "The conventional explanation for such increases is the cathodic deposition of electrolyte impurities on the cathode surface. However, all these samples were protected from the electrolyte inside the gas-pressure-tight hollow core of the cylindrical cathode. The only remaining possibility of contamination would be in the process of cathode preparation. .....It is possible that the high temperatures experienced by the welded region could have vaporized various impurities in the Pd and the vapors carried down for deposition on the Pd powder. While this scenario is plausible for the relatively volatile zinc, it is less likely for gold and iridium. For example, zinc has a boiling point of 907°C, whereas iridium and gold have boiling points of 4800°C and 2600°C respectively."

Due to experimental difficulties, the authors failed to confirm that the isotopic composition of zinc in the first three samples is different from that in the last sample. They were able to measure the amount of ^{64}Zn only; the amount of ^{68}Zn could not be determined. In the discussion of the results the authors speculate that the only exothermic "nuclear reaction capable of producing Zn-64 is the fission of palladium isotopes or proton capture in impurity copper….. " After providing an argument against the second possibility they write: "We are thus left with the possibility of Pd fission, a process giving about 20 to 30 Mev per fission (10-15 Mev per fission product atom)..... The proof of a nuclear source for the increased zinc (and possibly other multi-isotope elements), will be resolved by NAA or other methods that show the isotopic abundance ratios to be significantly different from those found naturally. Otherwise, a contamination source is indicated. The small increases in iridium and gold in the active samples relative to the virgin sample find no ready explanation."

I suppose that Dr. R. Park, an expert in surface science, read the report of Arata and Zhang before writing the "woodoo science" book (published in 2000). How does he distinguish real scientists from charlatans? But let me move to the most recent paper (2003) of Passell. I know that organizers of the 10th International Cold Fusion Conference, at which that paper was presented, personally invited Dr. Park to attend. Why did he, the official spokesman for APS (American Physical Society), decline the offer? Questions of that kind are always in my mind when I read good cold fusion papers. But that is not science. I do not know whether or not cold fusion claims are valid. But I am convinced that many cold fusion researcher are not charlatans and that their recent findings should be evaluated by appointed experts. Most of us are not equipped to conduct cold fusion experiments; that is why an authoritative evaluation would benefit all science teachers.

The title of the new paper of Passell is "$^{110}Pd/^{108}Pd$ Ratios and Trace Element Changes in Particulate Palladium Exposed to Deuterium Gas." The authors found that in palladium exposed to the deuterium gas (to produce excess heat in the cold fusion experiment of Ararta and Zhang) the $^{110}Pd/^{108}Pd$ ratio was 0.477 instead on 0.422. The 8% change in the isotopic composition of Pd is very significant. Unfortunately, a possible confirmation or refutation of changes in the isotopic composition of a trace element silver is only mentioned as work in progress. Interesting information on changes in the amounts of ^{109}Ag, ^{59}Co, ^{64}Zn, ^{191}Ir and ^{197}Au is also provided by the author. Here are the last two sentences from his last paper. "Probably the greatest revelation in this work is the possibility that trace elements may be significant participants in nuclear reactions in solids such as Pd so that focusing entirely on D+D fusion is not necessarily the only path forward in understanding these phenomena. Of course it is possible that some of the variations in impurity levels is simply random differences within a non-homogeneous batch of powdered Pd. Iridium and gold may be in this category, since no easy explanation for their changes have been found."

Comments

1) The NAA method is highly reliable; it has been used for decades in many applications. But it is not a universal method, like traditional mass spectroscopy. It is highly suitable for some isotopes and not suitable for others, even when only one chemical element is involved.

2) I suppose that NAA, when applicable, is much more sensitive than mass spectroscopy. That is why it should be used in the analysis of trace elements. But for the analysis of a main component in a sample, such as palladium, mass spectroscopy would be be more desirable that NAA. Why was the indirect NAA method chosen instead of the universal method of traditional mass spectroscopy? Probably because NAA is Passell's specialty.

3) Isotopic ratios of NAA are less informative than actual amounts of substances expressed in arbitrary units. We do not know if a change in the $^{110}Pd/^{108}Pd$ is due to an increase of ^{108}Pd or in a decrease in the ^{110}Pd. Traditional mass spectrometry would clarify this issue.

4) By using the AAA method Passell observed a large increase in the amount of ^{64}Zn. Such increase should not be identified with the increase of the total amount of zinc because 64Zn is only one of several stable isotopes. The identification would only be justifiable if the isotopic composition of Zn was the same in all four samples.

5) Traditional mass spectroscopy, of very high resolution, was an essential part of the methodology of Arata and Zhang. They used it to distinguish ^4He from D_2. I am surprised by the absence of references to studies conducted by traditional mass spectroscopy. Does it mean that nobody tried to compare isotopic compositions of Pd (before and after it was used in cold fusion experiments) by traditional mass spectrometry? It is hard for me to imagine that this was not done; an examination of a bulk element, in this case palladium, is usually easier than an examination of trace elements in it.

6) A panel of experts (appointed, for example, by the National Academy of Science, to investigate cold fusion claims) would have to decide on which experiments to focus. My recommendation would be

a) Arata and Zhang excess heat experiment with the follow up mass spectroscopic analysis of the bulk Pd and trace elements. Also a detailed chemical analysis of the so-called "impurities."

b) Jones's experiments on neutrons and charged particles. (10th International Cold Fusion Conference, August, 2003).
c) Karabut's experiment in which generation of excess heat was accompanied by generation of radioactive reaction products.
d) Iwamura experiment (10th International Cold Fusion Conference, August, 2003).

Fortunately, the authors of papers in which many essential CF experiments are described are still alive. The authors should be invited to repeat the experiments in front of critical experts appointed by the Academy. How else can the unhealthy situation (that resulted from the press release in March of 1989) be resolved?

127) Water remembers: Homeopathy does seem to be pseudoscientific

Ludwik Kowalski (1/31/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

On 1/30/04 I watched a TV fragment on homeopathy. It was a 20/20 “Give Me a Break” report by John Stossel on ABC . Those who defended homeopathy claimed that “water remembers.” The idea is to prepare a water solution of something that, in a strong dose, would produce sickness, or some other undesirable effect. A much weaker solution of the same thing causes the opposite effect, they said. For example, a person who can not fall sleep, after taking too much coffee, would fall asleep rapidly after drinking a highly diluted coffee. The claim is that a medicine can be effective even when it is diluted to a point at which the probability of finding a single molecule becomes practically zero. How can I accept this?

I have no doubt that some homemade remedies can be as effective as prescription drugs. Or that the “truly holistic” approaches are often desirable. But I can not accept the “water remembers” idea, as presented in the ABC program. Homeopathy became popular after a German doctor, Samuel Hahnemann, started promoting it two centuries ago. He was guided by the so-called law of similarities: '”That which makes you sick in large doses shall heal you in small doses.” That philosophical principle is likely to be consistent with some experimental facts (for example, vaccination) and be contradicted by others. It is not a law of nature confirmed by all available experimental facts. In my opinion those who defend the “water remembers” idea are pseudoscientists.

The only statement about homeopathic medication that I am willing to accept is that it cannot cause side effects or addiction, especially when the dilution process is carried out to the level of “nearly nothing is left.” One might say “water has an excellent memory for good things but no memory for bad things.” Hmm, what is the mechanism by which water distinguishes between what is and what is not good for a patient? Here is a brief description about how the remedies are made; I fetched it from the following Internet site:

http://www.webhealth.co.uk/Complementary_Health/Complementary_Therapies/
Complementary_Therapy_Overview/complementary_therapy_overview12.html

“ The remedies which homeopaths use come from many different sources. Most are derived from plants, but minerals, metals and some poisons which have been used medicinally for generations are also used. After initial preparation of the raw material the remedies are made by serial dilution and succession (vigorous shaking) in a solution of alcohol and water. This is done a few (three to four) times or up to many thousands of times. The liquid dilution is then used itself as a remedy or soaked into tablets or granules for convenience. The diluted remedies are described as being 'potentized', in recognition of the dynamic healing power they can stimulate.”

And here is an advertizing of “energized water;” it seems to be nothing but commercial deception and pseudoscience. “An Energy Mug to energize your water in 1-2 minutes.....Highly charged water inside the hollow of the mug transfers positive information to your drinks (water, juice, coffee, colas), giving them a positive spin and a sweeter, softer, less acidic taste. This information stays with the drink even when poured into another glass. (Do Not X-Ray Or Microwave).” What does it mean to “energize water?” What is “positive information?” In which form does is “stay with water?” What is the purpose of the last recommendation?

= = = = = = = = = = = = = = = = = = =

Since this is a short unit let me append to it a short e-mail message about BPL, the company described in my unit #47. This message, dated November 4, 2003 and signed by Charlie Arruda, was fetched by Google.

“I have a general business comment about Blacklight Power. It's been 12+ ‘years’ now and what started as a great ‘concept’ to provide an alternate energy supply is turning into another big ‘song and dance’ story. I have stuck with the hydrino group and initially was very excited about the Blacklight Power Company and its science/business. But now I'm wondering what happened and what must being going through the minds of their poor investors.

For instance, what happened to the very promising ‘Hydrino Hydride’ battery? I remember the nice pictures of the ‘Hydrino Hydride’ compounds and thought that was very impressive to have that much pure compound so early in their initial development. It all looked like a great ‘concept’, but after several years there is neither a ‘proof of concept’ demonstration nor viable product. I'm starting to think that hydrinos, if they exist in a stable state, are possibly very hard to control/use outside the low vacuum conditions (>1torr) of the plasma ‘test’ chambers and just aren't easily commercialized in large quantities - just like the early solar cells or the current carbon nanotubes (@ $500/gram). I wonder what the energy density would be at that pressure, most likely not much to commercialize. Maybe in 20 years there will be a way to use them in marketable quantities to become viable. Maybe the new ‘Electrokinetic Microchannel Battery"’concept will prove a better alternative... or maybe not. “

128) Screening or something else?

Ludwik Kowalski (2/13/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Steven Jones thinks that the D+D coulomb barrier for ions embedded in metals may be lowered significantly due to the phenomenon of screening. This, he wrote to me in private, has been confirmed by a large team of German scientists [F. Raiola et al., European Physical Journal A (13:377-382, 202)]. I should read this article when I find it. It reminded me the paper of Kasagi mentioned in the unit #17. Fortunately, the www.lenr-canr.com site has a paper that Kasagi presented at the 7th International Conference on Cold Fusion. I downloaded this paper [J. Kasagi et al., "Anomalously Enhanced D(d,p)T Reaction in Pd and PdO Observed at Very-Low-Energy Bombardments."] and read it critically. Here are my comments:

1) The idea of studying the enhancement of D(d,p)T cross section at very low energies in metals is great. Unfortunately, I have no access to earlier publications of Kasagi in which procedural details are said to be described in more details. What I have is not sufficient to be convinced.

2) The experiment was performed by using a thick target (d beam is stopped). Protons were counted by using the dE-E telescope of Si detectors; the first detector was only 50 microns thin. (Detectors of such thickness were not available when I was an active researcher.) Why the observed energy spectra of protons are not shown in the paper?

3) The target was thick and a large fraction protons was certainly not detectable. That fraction was energy-dependent; the lower the beam energy the larger the fraction. Some kind of procedure must have been used to correct for this effect. But I did not see the description of their procedure. Should I rule out a possibility that the so-called "enhancement" is due to the overcorrecting?

4) As indicated by the authors, the target itself (concentration of deuterons in metal) was not stable. This was probably due to large current beams (needed to observe rare protons). Is it conceivable that the so-called "enhancement" is due to target instabilities. The authors recognize this possibility and mention another possible source of a systematic error; the assume values of dE/dx for protons and deuterons at very small energies.

5) In the resume of Kasagi's paper, presented at the 10th International Conference on Cold Fusion, I see a statement that screening alone is not sufficient to explain the enhancements. Some other phenomena, the authors say, must also be contributing.

6) I suppose that Raiola's team was familiar with papers published by Kasagi's team. It will be interesting to see what Raiola thinks about Kasagi's papers.

= =

What is not possible in plasma (ionized gas), some say, might be possible in condensed matter. Let me illustrate this in terms of a coulomb barrier that prevents two ions from fusing at an ordinary temperature. To produce fusion in a gas one has two well known options: to increase the temperatures to millions of degrees or to electrically accelerate one of the ions. In a solid however one might imagine some additional scenarios. One of them is screening of positive ions by negative electrons, as suggested by Jones. And another is to produce some kind of a collective effect. Can the energy

needed to overcome the coulomb barrier be supplied (to a pair of embedded ions) from atoms surrounding them? If the total number of contributing atoms is one billion, for example, then only 0.001 eV of energy per atom would provide 1 MeV needed to produce fusion. That is my naive way of understanding arguments presented in some theoretical papers. I am referring to papers presented by S, Chubb T.Chubb and P. Hegelstein at the 10th International Conference on Cold Fusion. (More recent papers of these authors are going to be presented at the March 2004 meeting of American Physical Society. The abstracts can be seen at the APS web site
http://www.eps.org/aps/meet/MAR03/baps/abs/S9530.html)

Not having an accepted theory is the major weakness of those who investigate various cold fusion (CF) fields. But arguments about models should not be confused with arguments about the validity of experimental data. It is worth recalling that no theoretical model existed when excess heat from radium was discovered by Pierre Curie. The discovery of neutrinos, on the other hand, followed the opposite path; the existence of these hard to detect particles was first predicted theoretically and then confirmed via experimental investigations. Pauli's prediction, however, was triggered by calorimetric measurements of heat released in beta decay.

The major argument of those who rejected CF claims in 1989 was the fact that these claims could not be explained in terms of the accepted model of nuclear reactions. I think that it is OK to reject a model of a physical phenomenon on the basis of a conflict with experimental data but it is not OK to reject experimental data on the basis of a conflict with the model. Physical reality is much richer than man-made models. But that is a philosophical statement. In practice experimental findings conflicting with confirmed theories, as in the case of CF, should be scrutinized very carefully before being accepted.

In reading Kasagi's paper I noticed that A. Lipson, from Russian Academy of Sciences, was one of the coauthors. Like Jones, Lipson et al. demonstrated that 3 MeV protons are emitted from metallic foils loaded with hydrogen. In their setup protons were accompanied by alpha particles. That investigation has already been described in the unit # 28. Another investigation of Lipson et al., was presented at the 10th International Conference on Cold Fusion. The major tool in that study was the glow discharge chamber of Karabut et al. (already described in the unit #13). The main question was "how does the rate of emission of charged particles depend on the applied voltage?" These particles were detected with CR-39 detectors placed inside the chamber. The paper, entitled "Enhancement of DD-reaction Accompanied by X-ray Generation in a Pulsed Low Voltage High-Current Deuterium Glow Discharge with a Ti-Cathode," can be downloaded from the ICFF10 folder at
html://www.lenr-canr.org.

Here is the abstract of that paper: "Using noiseless solid state plastic track detectors (CR-39) and Al_2O_3:C thermo-luminescent (TLD) detectors, the yields of 3.0 MeV protons (from DD-reaction) and soft X-ray photons emitted from the cathode are studied in the pulsing-periodic deuterium glow discharge with Ti-cathode at low discharge voltages (ranging of 0.8-2.5 kV) and high current density (300 – 600 mA/cm^2). Analysis of DD-proton yield versus accelerating voltages, allowed to estimate the deuteron screening potential value Us at the deuteron energy range of $0.8 < Ed < 2.45$ keV. It was found a strong DD-reaction enhancement in glow discharge (the effective screening potential Ue = 610 ±150 eV) compared to that for accelerator experiments at higher deuteron energies (Elab >2.5 keV) and lower beam current density (50- 500 microA/cm^2). X-ray measurements showed an intensive (Ix = 10^{13}-10^{14} s^{-1}-cm^{-2}) soft X-ray emission (with a mean energy of quantum Ex = 1.2-1.5 keV) directly from the Ti cathode. The X-ray yield is strongly dependent on a deuterium diffusivity in the near -- the -- surface layer of cathode."

Note that the energy range at which the D(d,p)T reaction was studied (down to 0.8 keV) is below the range explored , with traditional accelerators. Nine references to studies conducted by using accelerators are made by Lipson et. al. The authors emphasize that studies of reaction yields at very low bombarding energies are highly significant in the context of astrophysical and thermonuclear processes. Such investigations seem to bridge a gap between cold fusion and traditional nuclear physics. The authors show that at the bombarding energy of 1 keV the number of 3 MeV protons is by nine orders of magnitude higher than theoretically expected. This refers to deuterons embedded in a Ti cathode and to a theory which agrees with experimental data at higher energies. In other words, the authors show that the accepted theory is not necessarily valid at very low energies and when targeted nuclei are not free to recoil, as they are in a hot plasma. The authors argue that the observed enhancement of the D(d,p)T reaction cross section is consistent with the

assumption that the coulomb barrier is lowered by 0.61 keV, for example, due to the screening by electrons.

= =

But what is screening?
How can all this be made meaningful to students in an introductory physics course? The concept of the coulomb barrier has already been described in the unit #40. To explain screening I would ask students to consider the following problem. Place two deuterons on the x axis, one at the origin and another at a distance x along the positive direction. Treat the second deuteron as a probe charge and calculate the electric potential as a function of x. This gives the familiar 1/x curve. If the attractive nuclear potential is very large at x<3 F and zero at all larger distances then the coulomb barrier is the same as the value of the electric potential at x=3. It is equal to 480 kV. Now place an electron at x=-5 F. The coulomb barrier is still electric potential at the location x=3 F. But it is now due to two point charges: the deuteron at x=0 and the electron at x=-5 F. The answer is 300 kV. Repeat the exercise when x2=-2 F. This time the coulomb barrier is 192 kV. Repeat it again to see the the coulomb barrier becomes zero when x2=0 (as one would expect without any calculations).

This simple numerical exercise is sufficient to convince students that presence of an electron,somewhere outside the two deuterons, has the effect on the coulomb barrier. Closer the electron smaller the barrier. Presence of two or more elections, as one can easily verify, would further reduce the coulomb barrier. This electric effect is can be called screening. Note that the value of x=3 was chosen because the range of nuclear forces was assumed to be 3 Fermis. The coulomb barriers would be considerably lower if the range of nuclear forces were larger. For the range of 4 fermis, for example, the coulomb barriers (with x2=-5 and -2 F) would be 200 and 120 kV, respectively. Even without screening the coulomb barrier would be 360 kV (with the range of 4 F) instead of 480 kV (with the range of 3 F).

It is clear that small distances between electrons and deuterons are extremely rare in a low pressure gas (plasma). But in condensed matter average distances between atoms are much shorter and a possibility of screening can be envisaged, especially in some metals. It is well known that in metals not all electrons orbit around atomic nuclei. It is possible to speculate that clouds of electrons are formed in some regions of metallic structures, perhaps near the boundaries of microcrystals where the D ions are trapped? Billions of Ti atoms would be involved to keep them there. Conditions for forming electron configurations which lower coulomb barriers significantly are probably rare. In some places the lowering of coulomb barriers might be very small in other it can be very large. According to Lipson et al., the average coulomb barrier lowering, in Ti, is about 0.6 kV. This is a small fraction of the two-body barrier, such as 200 kV. It is counterintuitive to think that by reducing the barrier from 200 to 199.4 kV, for example, one could increase the proton emission rate by the factor of one billion, as reported in the paper. But why should my intuition be trusted in the field about which I know so little? The purpose of this essay is nothing more than to clarify the meaning of the term “screening.”

It should be clear that one-dimensional setups of charges, and an arbitrarily chosen shape of the nuclear potential (rectangular with a given range, such as 3 F or 4 F) are not reliable for calculating coulomb barriers with or without screening. But they are sufficient to explain what screening is. To estimate the height of the coulomb barrier, without screening, one should look at the energy dependence of fusion cross sections. Most nuclear physics textbooks would show such experimental data. I am now looking at the curves for the DD reactions. They tell me that the coulomb barrier is probably omewher between 100 kV and 200 kV. The yields of neutrons and protons decrease very rapidly when kinetic energies of relative motion are less than 50 keV. (That is why thermonuclear reactions in gasses are studied at extremely high temperatures.)

= =

Here is a message, inspired by the above, that I just posted on the Phys-L list.

1) In electrostatic you might ask students to estimate the coulomb barrier preventing positive D ions from fusing at low temperatures. Here is my suggestion. First tell students that in addition to repulsive forces the ions attract each other by very strong nuclear forces. But these forces do not obey the 1/r^2 law. They are negligibly small when r is above a distance R (called range). For x<R the attractive nuclear forces are much larger than repulsive electric forces. That would be a sufficient justification for defining the coulomb barrier, CB, as the value of the electric potential at x=R.

The rest is trivial. Assume that R=3 F, for example, and calculate the CB. Note that F is the unit of length (femtometer or 10^-15 m). My answers were 480 kV and 360 kV, at R=3 F and 4 F, respectively. Depending on your predisposition, you may or may not like linking this problem with the cold fusion controversy.

2) If you do like this idea then consider addressing the screening effect. Some scientists say that screening is possible when D ions are embedded in metals, such as Pd or Ti. Simply stated, and without trying to argue about what causes screening (local clouds of electrons at crystal's boundaries?) one can simply declare: screening consists of lowering of the coulomb barrier by nearby electrons.

To illustrate screening do the following. Place one deuteron at x=0 at treat the other deuteron, at x>0, as a probe charge. That is what I did to calculate coulomb barriers. Then place an electron at some negative value of x, for example, -2 F. The CB is now V=V1 + V2 (where V1 is the positive part due to the deuteron and negative V2 is the negative part due the electron). You will see that CB approaches zero when electron is approaching the origin, as it should be. My answer, for R=4 F, was CB=120 kV for the electron placed at x=-2 F. And nothing prevents you from introducing more than one screening electron.

Suppose a single electron at x=10 A =100000 F is replaced by a negative particle of variable charge. Assuming R=4 F, how does the magnitude of the negative charge affect the coulomb barrier? It turns out that the charge of only 250000*e is sufficient to eliminate the coulomb barrier. Here my results;

charge in 10^5*e QB in kV

2.1 0.0015
2.0 72
1.0 216
0.5 288
0.1 346
0.01 358
0.00 360 (an ideal two-body barrier)

I find them shocking. First because the distance of 10 A is about ten times larger than the distance between atoms in most metals. And second because the number of electrons needed to eliminate the barrier (for that distance) is a negligible fraction of free electrons in each cubic micron. But not being a solid state physicist I do not know how to explain the postulated clustering of free electrons.

4) Yes, I know that three or more particles would usually not be at rest on the x axis. And I know that the nuclear potential is not a rectangular well. My goal is to estimate the orders of magnitude of CB, and to illustrate the idea of screening.

5) By the way, we usually think that the so-called "free electrons" in metals are uniformly distributed, like in ionized gases. What evidence do we have for this? Yes,
I know that the physics of surfaces is very complex, even for something familiar, such as friction.

6) No, I am not trying to poison your mind with heretical pseudo science. This piece is essentially an attempt to show how a trivial electrostatic problem can be made relevant, even in an introductory course. Those who do not want to deal with the concept of screening in condensed matter might ask students "why do fusion reactions in ionized gasses occur at stellar temperatures only?" This will naturally lead to two interesting topics outside electrostatics: the QM tunneling and the Maxwellian distribution of kinetic energies of ions at various temperatures. Students love digressions but one

must make sure that the main topic is electrostatics.

==========

ADDED ON JULY 23, 2011

A stranger who read the unit 128 just sent me a private message. He wrote: *"Just a couple comments on the above article..... I agree that screening would seem to play a minor role and would not be able to change the Coulomb potential much in matter in which the electrons were disposed symmetrically around the nucleus. But asymmetries do occur. For instance in highly polarized matter. I've been studying dielectrics such as barium titanate which have been produced with permittivities in excess of 30,000. In such materials at high electric fields the local field on the charges in the material can be ~10TV/m. This would certainly introduce an asymmetry in the dispositions of electrons in the nucleus. It wouldn't be too difficult to set up an experiment to test this."*

What kind of experiment can be performed with barium titanite [BaTiO3]? Suppose this dielectric is used as a target bombarded by 3 MeV protons. Suppose the cross section of a known Ti(p,n) reaction is measured. Then the same is done with a metallic Ti target. If the coulomb barrier for titanium in the dielectric is really lower than for the Ti in the metal then the cross section should be target-dependent. The cross section for the dielectric target, could be several times larger for the metallic target. Naturally, one needs a well equipped nuclear laboratory.

This was posted in the private discussion list for CMNS researcher. Then I added that such result would be the first demonstration, outside the CMNS field, that structure of condensed matter can have a dramatic effect on a nuclear process. The accepted textbook wisdom is that nuclear processes are not dependent on changes taking place at the atomic level (such as Ti metal versus Ti in a dielectric). A reproducible difference in cross sections, for example, by a factor of 2 or 10, would probably produce a dramatic change in the attitude of most scientists toward our CMNS field.

One researcher referred to Kasagi experiments. Responding to this, I wrote that Kasagi's energy region was several eV. Why did I suggest 3 MeV? Because the cross section at ~3 MeV should be many orders of magnitude larger (easier to measure) than at ~10 eV. On the other hand the 3 MeV is still below the region where the dependence of the cross section on energy becomes less steep. All this is based on what I remember, not on literature. Below are my additional reflection, also posted on the CMNS list.

1) For the most common (74%) isotope, ^{48}Ti, the (p,n) reaction will not take place when the energy of protons is 3 MeV, as I suggested. Why not? Because the Q value is 4.7 MeV The needed energy should be at least 5 MeV. This still is less than the coulomb barrier (~ 7 MeV). I would not hesitate using 5.5 MeV protons.

2) The coulomb barriers are practically identical (about 7MeV) for all stable isotopes of titanium [46 (8%), 47 (6%), 48 (74%) 49 (6%) and 50 (5%)]. But the Q values are likely to be different for other isotopes.

3) Let me go back to the ^{48}Ti target. The probability of Ti+p fusion (formation of an excited ^{49}V compound nucleus) depends only on the height of the coulomb barrier. But the cross section for a particular reaction, such as the Ti(p,n), depends on how many other "output channels" are also open (energetically possible), at a given excitation energy of the compound nucleus. I am thinking about the (p,d), (p,t), (p,al), etc. The Q values of competing reactions must be known to theoretically estimate a particular cross section.

4) What is the Q value of the (p,al) reaction: 48Ti + p --> 45Sc + alpha ? It happens to be +2.6 MeV. In other words, the (p,al) reaction is exothermic; it would take place, even for 3 MeV protons, and below. Considering this fact I would measure the (p,al) cross sections, not the (p,n) cross sections, as initially suggested. And why not the (p,d) or (p,t) reaction? These reactions can also be used to show that the expected effect is real. To answer this question I would have to calculate the Q values of these reactions. Detecting and identifying energetic charge particles is likely to be easier (less costly) than detecting and identifying energetic neutrons.

5) The less demanding (lest costly) method of validation of the expected effect would be to measure the elastic

scattering cross section, ES for alpha particles, for example, at 30 or 45 degrees. The formula for the ES is well known (and experimentally verified for thin metallic targets). The ES is inversely proportional to the square of the coulomb barrier. Once the ES is measured the barrier can be calculated. Why is this method less desirable than measuring a cross section of a nuclear reaction induced by protons? Because a sufficiently strong alpha source is much less expensive than a proton accelerator. The source could be placed into a small vacuum chamber and CR-39 chips could be used to detect scattered alpha particles.

But, as the saying goes, the devil is in the details. The most difficult part, for me, would be preparation of two thin targets, metallic and dielectric. The word "thin" stands for the "thin in comparison with the range of projectiles in it." Why is this important? Because the kinetic energy of projectiles must be well defined; it appears in the ES formula. Suppose that thicknesses of two targets are known to be the same. Suppose that each target is bombarded with a collimated beam of alpha particles for one hour. Suppose the number of particles detected at 30 degrees, for a metallic target is 1000. Suppose the same is done for the dielectric target and the number of particles detected at 30 degrees is 2000, under otherwise identical conditions. That would mean the cross section for the dielectric target is twice as large as for the metallic target. It would also mean that the coulomb barrier in the dielectric environment is four times lower than in the metallic environment.

6) Yes I know that gedanken experiments are much easier than real experiments. In reality the two targets would probably have slightly different thicknesses. A correction would have to be made, to account for this. Another correction should be made to account for the presence of barium atoms and oxygens atoms in the dielectric target. These atoms would also be scattering alpha particles. To avoid a serious error (an illusion of the coulomb barrier lowering) , I would place thin layers of Ba and O atoms (in one form or another) on the metallic target, matching the mg/cm^2 of Ba and O in the dielectric target. Similar considerations would be necessary for experiments based on nuclear reactions, rather than on scattering. Yes, the devil is in the details.

129) Consumed by a Quixotic fiasco?

Ludwik Kowalski (229/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

In a message (2/25/04) to a friend, a retired physics teacher, I wrote: " I tried to summarized what I have learned about cold fusion in a short article that has already been submitted to a journal. They will probably reject it and I might try another journal, probably outside the US. The article addresses readers like you and I would very much appreciate your reaction to it (mostly in terms of readability). Can you spare about 30 minutes to read my article? I would be happy to send it to you as an attached file. On the other hand, I will understand your preference for not being involved. It is a highly unusual "forbidden" topic. But please do not share the article with others at this time. Your comments will remain confidential (if you wish) or I might decide to thank you for them at the end of the article (with your permission). My goal is not to argue for or against cold fusion; it is to convince leaders of our scientific establishment that another formal evaluation of the CF field is desirable. (P.S. I will retire at the end of this semester and becoming a full time CF researcher is in my mind. I am already preparing an experiment to verify the 'emission of protons' claim.")

And here is the reply; it is typical of those who have made their mind long ago and do not want to be involved. "Since you said it would take thirty minutes, I'm afraid I can't afford to read it. I am not familiar with the field, so it would take me much, much longer to read it critically. It seems to me that one can only learn more about this field by doing more and better experiments. I am familiar with the experiments done by Mike Hayden, Walter Hardy et al. [1990 reference is given] and unless a better experiment is done to invalidate that result I am satisfied that there is nothing to the original claims. Jones' muon catalyzed fusion . . . is, of course, physically sound, if not economically so. The Pons and Fleischmann stuff, however, is incompetent. I hope that you can find a better, more rewarding pursuit for your retirement. You and I have many years to go, but not as many as we've already had. I would not like to see your "declining years" consumed by a Quixotic fiasco. .....I wish you well in whatever you do, but I respectfully suggest that you pick a topic with better a priori prospects than 'cold fusion' for your retirement efforts."

Replying to the above I wrote: "I will not bother you with my paper. Cold fusion refers to several claims which may and may not be connected. Some are definitely wrong, as I convinced myself last year by repeating an experiment (together with H.F. who made the original claim several years ago and who invited me to his private lab).

I want to focus on a recent claim made by a highly respected scientist. A good experiment should always produce an answer, either YES or NO, for a well formulated question. Being able to produce a clear answer about that particular claim will make me happy, no matter what the answer will be. That claim, by the way, has nothing to do with excess heat or with alchemy.

Most people are not familiar with what was going on in the CF field in the last ten years; their opinion was formed on the basis of the soap opera of 1989-1999. My article is a brief summary of what was going on in the CF field recently; it was written for scientifically literate readers. It would make me very happy to see it in print. Yes, we do not have too many years left and we should be selective. I will keep this in mind in deciding how long to explore the 'unexpected protons' claim; it is one aspect of CF that I feel qualify to address. ....."

130) Sonofusion

Ludwik Kowalski (3/3/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

March 3, 2004 New York Times (from the on-line editin; sent by a friend)

Experts Say New Desktop Fusion Claims Seem More Credible

By KENNETH CHANG

Scientists are again claiming they have made a Sun in a jar, offering perhaps a revolutionary energy source, and this time even some skeptics find the evidence intriguing enough to call for a closer look. Using ultrasonic vibrations to shake a jar of liquid solvent the size of a large drink cup, the scientists say, they squeezed tiny gas bubbles in the liquid so quickly and violently that temperatures reached millions of degrees and some of the hydrogen atoms in the solvent molecules fused, producing a flash of light and energy. "It can do some interesting science stuff as is," said Dr. Richard T. Lahey, a professor of engineering at Rensselaer Polytechnic Institute and an author of a paper describing the findings that will appear in the journal Physical Review E.

"Our interests are to see if we can't scale it up to something more exciting," he said. The experiment could conceivably shrink the science of fusion ? slamming hydrogen atoms together, producing heat and light ? from giant, expensive reactors to the tabletop. When this team of researchers made the same claim in an article in the journal Science two years ago, many scientists reacted with skepticism, even ridicule. But new experiments, using better detectors, offer more convincing data that the phenomenon is real. "We've addressed all the issues and now they all speak for themselves with far greater intensity than they did before," said Dr. Rusi P. Taleyarkhan, the scientist who conducted the experiments at Oak Ridge National Laboratory in Tennessee and is a professor of nuclear engineering at Purdue University.

Skepticism remains, but Dr. Lawrence A. Crum, a professor of electrical engineering at the University of Washington who was highly critical of the Science paper, said the new work was "much better" and deserved attention to determine whether the effect could be reproduced. "It's getting to the point where you can't ignore it," Dr. Crum said. For decades, physicists have dreamed of harnessing the ferocious alchemy of the Sun as a clean, limitless energy source. Most experiments have been conducted in giant, expensive reactors using magnetic fields to confine the ultrahot gases. In contrast, the new experiment, which cost less than $1 million, uses the power of sound to create energy comparable to the inside of stars. To many scientists, however, the phenomenon, nicknamed sonofusion, bears uncomfortable similarities to "cold fusion," which has now been discredited.

Sonofusion has already achieved more scientific respectability than cold fusion ever did, with two articles published in major journals. And unlike cold fusion, sonofusion is based on known science. Scientists have long observed a

phenomenon known as sonoluminescence, in which a burst of ultrasound causes a bubble in a liquid to collapse and emit a flash of light; some have speculated that the gases trapped in the collapsing bubbles could be heated to temperatures hot enough for fusion to occur.

Still, controversy enveloped the Science paper two years ago. The new research by Dr. Taleyarkhan and Dr. Lahey provides a much clearer picture of neutrons that are ejected when fusion occurs. Many scientists like Dr. Glenn Young, head of the physics division at Oak Ridge, said the experiment was solid, but still incomplete. "Neutrons are slippery little rascals," he said. "They can fool you. They can bounce and show up around corners you don't expect."

==========

A speculation:
In my mind sonofusion belongs to the area of hot fusion. The temperature of a rapidly compressed droplet of gas or vapor increases rapidly to a level at which some ions have enough kinetic energy (Maxwell tail) to fuse. The same is true for nuclear fusion induced by highly focused energetic laser beams of short duration. But what if further investigations will show that the dominant product of the D+D sonofusion is ^{4}He rather than ^{3}He and ^{3}H? In that case one would have to say that sonofusion is totally different from the thermonuclear fusion in hot plasma. I do not think that this will happen; a collapsing droplet is not surrounded by a lattice of positive ions. That metallic latice, according to some theoretical cold fusion people (Hegelstein, Chub and Chub), is essential to produce ^{4}He instead of lighter products. But this should not prevent one from trying to measure concentration of ^{4}He in heavy water after generating a lot of sonofusion events. Perhaps that concentration does increase significantely. This would indicate that the number of fusion events is higher than what one might infer from the number of neutrons. Another thing worth measuring is the excess heat; is it about 23 MeV per event (as some cold fusion people claim) or is it about 3 MeV (as in hot fusion)? Somebody will probably increase the rate of producing collapsing bubbles to make such difficult measurements possible.

==========

P.S.
In browsing the Internet I discovered the abstract of a paper of Roger Stringham, reporting on new sonofusion results. The paper will be presented at the March 2004 meeting of APS. I was not aware of this paper when the above speculation was composed. It is interesting that the paper has been placed into a session devoted to cold fusion. What a coincidence; the author is talking about measurable amounts of ^{4}He (up to concentration 100 times higher than in air) and excess heat (released without radiation). I was also not aware that the DD fusion takes place on the surface of a "foil lattice." The author states that compressed bubbles of D_2O (density of deutrons 10^{25} pec cc) are implanted into palladium before fissioning. The term “cavitationally induced fusion” is used in the abstract.

What kind of fusion is it, hot or cold? Producing excess heat without producing radiation seems to indicatative of cold fusion. The New York Times article, on the other hand, refers to emission of neutrons, as in hot fusion. Do Stringham and Lahey describe very different experiments? Stringham’s findings, if confirmed, would open a new field in the area of cold fusion. I should learn more about this and summarize the result in another unit. A popularizing article summarizint the situation in thermo-nuclear field (March 18, 2002, Business Week, in Science and Technology section) lists Stringham and Lahey as pioneers of sonofusion. Lahey was the coauthor of the Oak Ridge paper that started the new excitment about thermonuclear energy from another tabletop setup. Stringham is a cold fusion researcher; look for a description of his sonofusion work (by Eugene Mallove) at:

http://www.infinite-energy.com/iemagazine/issue42/breakingnews.html

On March 2, 2004 work of Lahey, a retired scientist, was described by Rusi in Pardue News. The article is available over the Internet at:

http://news.uns.purdue.edu/html4ever/2004/0400302.Taleyarkhan.fusion.html

APPENDIX:

Here is this article. Will Dr. Park also call it voodoo science? Sonofusion was not confirmed by two physicists from Oak Ridge one year ago.

Evidence bubbles over to support tabletop nuclear fusion device

WEST LAFAYETTE, Ind. – Researchers are reporting new evidence supporting their earlier discovery of an inexpensive "tabletop" device that uses sound waves to produce nuclear fusion reactions.
Rusi Taleyarkhan

The researchers believe the new evidence shows that "sonofusion" generates nuclear reactions by creating tiny bubbles that implode with tremendous force. Nuclear fusion reactors have historically required large, multibillion-dollar machines, but sonofusion devices might be built for a fraction of that cost.

"What we are doing, in effect, is producing nuclear emissions in a simple desktop apparatus," said Rusi Taleyarkhan, the principal investigator and a professor of nuclear engineering at Purdue University. "That really is the magnitude of the discovery – the ability to use simple mechanical force for the first time in history to initiate conditions comparable to the interior of stars."

The technology might one day, in theory, lead to a new source of clean energy. It may result in a new class of low-cost, compact detectors for security applications that use neutrons to probe the contents of suitcases; devices for research that use neutrons to analyze the molecular structures of materials; machines that cheaply manufacture new synthetic materials and efficiently produce tritium, which is used for numerous applications ranging from medical imaging to watch dials; and a new technique to study various phenomena in cosmology, including the workings of neutron stars and black holes.

Taleyarkhan led the research team while he was a full-time scientist at the Oak Ridge National Laboratory, and he is now the Arden L. Bement Jr. Professor of Nuclear Engineering at Purdue.

The new findings are being reported in a paper that will appear this month in the journal Physical Review E, published by the American Physical Society. The paper was written by Taleyarkhan; postdoctoral fellow J.S Cho at Oak Ridge Associated Universities; Colin West, a retired scientist from Oak Ridge; Richard T. Lahey Jr., the Edward E. Hood Professor of Engineering at Rensselaer Polytechnic Institute (RPI); R.C. Nigmatulin, a visiting scholar at RPI and president of the Russian Academy of Sciences' Bashkortonstan branch; and Robert C. Block, active professor emeritus in the School of Engineering at RPI and director of RPI's Gaerttner Linear Accelerator Laboratory.

The discovery was first reported in March 2002 in the journal Science.

Since then the researchers have acquired additional funding from the U.S. Defense Advanced Research Projects Agency, purchased more precise instruments and equipment to collect more accurate data, and successfully reproduced and improved upon the original experiment, Taleyarkhan said.

"A fair amount of very substantial new work was conducted, " Taleyarkhan said. "And also, this time around I made a conscious decision to involve as many individuals as possible – top scientists and physicists from around the world and experts in neutron science – to come to the lab and review our procedures and findings before we even submitted the manuscript to a journal for its own independent peer review."

The new findings were scrutinized by experts at Oak Ridge.

"There was a great deal of internal review at Oak Ridge National Laboratory before the paper was submitted to the journal for external review," said Lee L. Riedinger, deputy for science and technology at Oak Ridge. "It is clear that Rusi's new data are more significant statistically than his earlier data. This is an exciting result, even if I do not understand the origin of the effect."

Riedinger said new experiments should be conducted to check the findings and to spur further research.

The device is a clear glass canister about the height of two coffee mugs stacked on top of one another. Inside the canister is a liquid called deuterated acetone. The acetone contains a form of hydrogen called deuterium, or heavy hydrogen, which contains one proton and one neutron in its nucleus. Normal hydrogen contains only one proton in its nucleus.

The researchers expose the clear canister of liquid to pulses of neutrons every five milliseconds, or thousandths of a second, causing tiny cavities to form. At the same time, the liquid is bombarded with a specific frequency of ultrasound, which causes the cavities to form into bubbles that are about 60 nanometers – or billionths of a meter – in diameter. The bubbles then expand to a much larger size, about 6,000 microns, or millionths of a meter – large enough to be seen with the unaided eye.

"The process is analogous to stretching a slingshot from Earth to the nearest star, our sun, thereby building up a huge amount of energy when released," Taleyarkhan said.

Within nanoseconds these large bubbles contract with tremendous force, returning to roughly their original size, and release flashes of light in a well-known phenomenon known as sonoluminescence. Because the bubbles grow to such a relatively large size before they implode, their contraction causes extreme temperatures and pressures comparable to those found in the interiors of stars. Researchers estimate that temperatures inside the imploding bubbles reach 10 million degrees Celsius and pressures comparable to 1,000 million earth atmospheres at sea level.

At that point, deuterium atoms fuse together, the same way hydrogen atoms fuse in stars, releasing neutrons and energy in the process. The process also releases a type of radiation called gamma rays and a radioactive material called tritium, all of which have been recorded and measured by the team. In future versions of the experiment, the tritium produced might then be used as a fuel to drive energy-producing reactions in which it fuses with deuterium.

Whereas conventional nuclear fission reactors produce waste products that take thousands of years to decay, the waste products from fusion plants are short-lived, decaying to non-dangerous levels in a decade or two. The desktop experiment is safe because, although the reactions generate extremely high pressures and temperatures, those extreme conditions exist only in small regions of the liquid in the container – within the collapsing bubbles.

One key to the process is the large difference between the original size of the bubbles and their expanded size. Going from 60 nanometers to 6,000 microns is about 100,000 times larger, compared to the bubbles usually formed in sonoluminescence, which grow only about 10 times larger before they implode.

"This means you've got about a trillion times more energy potentially available for compression of the bubbles than you do with conventional sonoluminescence," Taleyarkhan said. "When the light flashes are emitted, it's getting extremely hot, and if your liquid has deuterium atoms compared to ordinary hydrogen atoms, the conditions are hot enough to produce nuclear fusion."

The ultrasound switches on and off about 20,000 times a second as the liquid is being bombarded by neutrons.

The researchers compared their results using normal acetone and deuterated acetone, showing no evidence of fusion in the former.

Each five-millisecond pulse of neutrons is followed by a five-millisecond gap, during which time the bubbles implode, release light and emit a surge of about 1 million neutrons per second.

In the first experiments, with the less sophisticated equipment, the team was only able to collect data during a small portion of the five-millisecond intervals between neutron pulses. The new equipment enabled the researchers to see what was happening over the entire course of the experiment.

The data clearly show surges in neutrons emitted in precise timing with the light flashes, meaning the neutron emissions are produced by the collapsing bubbles responsible for the flashes of light, Taleyarkhan said.

"We see neutrons being emitted each time the bubble is imploding with sufficient violence," Taleyarkhan said.

Fusion of deuterium atoms emits neutrons that fall within a specific energy range of 2.5 mega-electron volts or below, which was the level of energy seen in neutrons produced in the experiment. The production of tritium also can only be attributed to fusion, and it was never observed in any of the control experiments in which normal acetone was used, he said.

Whereas data from the previous experiment had roughly a one in 100 chance of being attributed to some phenomena other than nuclear fusion, the new, more precise results represent more like a one in a trillion chance of being wrong, Taleyarkhan said.

"There is only one way to produce tritium – through nuclear processes," he said.

The results also agree with mathematical theory and modeling.

Future work will focus on studying ways to scale up the device, which is needed before it could be used in practical applications, and creating portable devices that operate without the need for the expensive equipment now used to bombard the canister with pulses of neutrons.

"That takes it to the next level because then it's a standalone generator," Taleyarkhan said. "These will be little nuclear reactors by themselves that are producing neutrons and energy."

Such an advance could lead to the development of extremely accurate portable detectors that use neutrons for a wide variety of applications.

"If you have a neutron source you can detect virtually anything because neutrons interact with atomic nuclei in such a way that each material shows a clear-cut signature," Taleyarkhan said.

The technique also might be used to synthesize materials inexpensively.

"For example, carbon is turned into diamond using extreme heat and temperature over many years," Taleyarkhan said. "You wouldn't have to wait years to convert carbon to diamond. In chemistry, most reactions grow exponentially with temperature. Now we might have a way to synthesize certain chemicals that were otherwise difficult to do economically.

"Several applications in the field of medicine also appear feasible, such as tumor treatment."

Before such a system could be used as a new energy source, however, researchers must reach beyond the "break-even" point, in which more energy is released from the reaction than the amount of energy it takes to drive the reaction.

"We are not yet at break-even," Taleyarkhan said. "That would be the ultimate. I don't know if it will ever happen, but we are hopeful that it will and don't see any clear reason why not. In the future we will attempt to scale up this system and see how far we can go."

ABSTRACT

Additional Evidence of nuclear emissions during acoustic cavitation

R.P. Taleyarkhan 1, J.S. Cho 2, C.D. West 3, R. T. Lahey 3, Jr., R.I. Nigmatulin 4, and R.C. Block 3

1Purdue University, West Lafayette, Indiana 47907, 2Oak Ridge Associated Universities, Oak Ridge, Tennessee 37830, 3Rensselaer Polytechnic Institute, Troy, New York 12180,
4Russian Academy of Sciences,
6 Karl Marx Street, Ufa 450000, Russia

Time spectra of neutron and sonoluminescence emissions were measured in cavitation experiments with chilled deuterated acetone. Statistically significant neutron and gamma ray emissions were measured with a calibrated liquid-scintillation detector, and sonoluminescence emissions were measured with a photomultiplier tube. The neutron emission energy corresponded to <2.5 MeV and had an emission rate of up to ~$4*10^5$n/s. Measurements of tritium production were also performed and these data implied a neutron emission rate due to D-D fusion which agreed with what was measured. In contrast, control experiments using normal acetone did not result in statistically significant tritium activity, or neutron or gamma ray emissions.

131) Jones's manuscript on history of cold fusion at BYU

Ludwik Kowalski (3/5/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

An explanation

On January 6, 2004 I visited Steven Jones at BYU (Brigham Young University) in Utah. Recent investigations of Jones et al. are described in units #113 and #124. The purpose of my visit was to see the instruments described in papers he presented at the 10th International Cold Fusion Conference (August 2004) and to talk about our possible cooperation. During that visit Steven mentioned his unpublished paper devoted to history of cold fusion. I said that I would be very interested in reading it. Then I added that readers of this web site, many of whom are physics teachers, might also be interested in that paper. Such a manuscript, written by a scientist whose work triggered the famous cold fusion controversy, is a historic document that should be available to the scientific community. Steven agreed and today I received that paper. It is a priviledge to post it here.

From a photo of Steven Jones taken during the 10th International Conference on Cold Fusion (October, 2003).

====================

BRIEF HISTORY OF COLD FUSION AT BRIGHAM YOUNG UNIVERSITY

By BYU Professors Jae Ballif, William Evenson, and Steven Jones

An outline:

I. Scientific Team

II. History

A. Scientific paper on cold fusion published March 1986 (submitted June 1985) by Jones and Van Siclen
   1. Theory proposed which presaged the Brigham Young University experiments
   2. "Piezonuclear fusion" used by Steven Jones of Brigham Young University to describe cold fusion

B. Brigham Young University Physics Colloquium 12 March 1986
   1. E. Paul Palmer suggested geophysical applications

C. Report to DOE (Department of Energy) 13 May 1986

D. Brigham Young University's experimental program
   1. Planning began in March 1986
   2. Use of Pd, Li, Al, Cu, Ni, Pt, etc. under non-equilibrium conditions, was outlined 7 April 1986. Jones' lab notebook page was notarized that day.
   3. Geophysical evidence for cold/piezonuclear fusion was sought in the scientific literature as early as April 1986
   4. Electrochemical cell built and measurements taken beginning May 1986
   5. Work on a highly sensitive, energy resolving neutron detector was begun in 1986, since neutrons of the correct energy are a signature for nuclear fusion
   6. Research papers presented on cold/piezonuclear fusion experiments in March and April 1988
   7. Experiments planned, research program set out and pursued vigorously
   8. Publishable results

E. Discussions with scientists at other institutions (1986-1988)

III. Scientific Contacts with University of Utah Researchers

A. Steven Jones reviews proposal by Pons and Fleishmann at Request of DOE 20 September 1988

B. Jones offered to cooperate with Pons and Fleishmann
   1. Pons responded with telephone call December 1988
   2. Jones offered use of neutron detector
   3. Pons and Fleishmann visited Brigham Young University laboratory, 23 February 1989
   4. Researchers agreed to work toward simultaneous publication

IV. Contacts Between University Administrators

A. Telephone discussion between President of University of Utah and Provost of Brigham Young University, 3 March 1989

B. Meeting between Brigham Young University and University of Utah administrators and principle scientists at Brigham Young University, 6 March 1989

C. Agreements from 6 March 1989 meeting
   1. Simultaneous publications
   2. Publication prior to APS meeting (May 1989) where Jones was scheduled to speak
   3. Exchange of preprints
   4. No further public comments on results of research until papers submitted

David Mince
Eugene Sheeley
Paul Dahl
Paul Banks
S. Seth Jones
David E. Jones

D. University of Arizona Faculty Members - Department of Physics

Johann Rafelski

II. History

A. Scientific paper published March 1986 (submitted June 1985)

The roots of our work regarding piezonuclear fusion are described in a scientific paper published in the Journal of Physics G: Nuclear physics, 12: 213-221. This paper was received by the journal on 12 June 1985 (over three years before we heard of Pons and Fleischmann, or of Andrei Lipson in Russia, or of their related work) and published in March 1986.

A1. Theory proposed which presages Brigham Young University experiments

The detailed mathematical framework given in the paper was worked out primarily by Dr. Clinton Van Siclen, author on the paper with Dr. Steven E. Jones. The paper discusses fusion at room temperature and how this might be enhanced by increasing the density of hydrogen isotopes. The paper discusses the transition of hydrogen to the metallic state under high pressures and other technical points. One significant concept explored in this paper is that a hypothetical particle "with mass twice that of the electron" could lead to room temperature fusion at a rate of approximately one fusion per minute per kilogram of deuterium. This is close to the actual rates observed in later experiments at Brigham Young University by Jones and colleagues, and the theoretical framework given in this early publication continues to be a possible explanation for the cold/piezonuclear fusion effect. Indeed, this paper is referred to in our later papers on the Brigham Young University experiments since it provides a theoretical, mathematical foundation for cold fusion.

A2."Piezonuclear fusion" used by Steven Jones of Brigham Young University to describe cold fusion

In addition to initiating the 1985 study, Steven Jones (one of the authors) coined the term "piezonuclear fusion" in analogy to the term "thermonuclear fusion," to indicate that the proposed approach is to induce fusion by "squeezing" the hydrogen nuclei together at near room temperatures rather than by heating them to very high temperatures. (The prefix "piezo-" comes from a Greek work meaning to squeeze or compress.) Dr. Paul Palmer used the term "cold fusion" beginning in early 1986.

B. Brigham Young University Physics Colloquium 12 March 1986

E. Paul Palmer suggested geophysical applications

The paper was published in March 1986, and on March 12, 1986 many of the concepts in the paper were described by Dr. Jones at a Colloquium of the BYU Physics Department. BYU Physics Professor Paul Palmer was present and associated these ideas with geological data on heat and helium-3 which are correlated in volcanoes and other thermal regions of the earth. Both heat and helium-3 are released in fusion reactions (proton-deuteron and deuteron-deuteron reactions). Dr. Palmer suggested that rock, lava, or crystals in the earth might help to catalyze the fusion reaction. This creative leap is recorded in Dr. Palmer's logbook, dated March 13, 1986 in some detail (copies available on request to BYU Physics Department).

C. Report to DOE 13 May 1986

Our work on cold piezonuclear fusion was reported to the DOE in the 1985-86 Annual Performance Report, dated 13 May 1986, along with three related documents: the Van Siclen/Jones paper on piezouclear fusion, a note entitled "Experiments in Cold Fusion" dated 28 March 1986 by Paul Palmer; and "Comments on Catalyzed Fusion," a note by Steven Jones dated 1 April 1986. It was at this time that Prof. Jones received permission from the DOE funding agent R Gajewiski to pursue research on this aspect of cold nuclear fusion under an already existing DOE grant to Brigham Young University for muon-catalyzed fusion research.

D. Brigham Young University's experimental program

D1. Planning began in March 1986

As a result of discussions generated by the Physics Department colloquium by Dr. Jones on March 12, 1986, an experimental program was worked out to test these new ideas. An important discussion meeting was held at BYU on April 7, 1986, involving Profs. Czirr, Jones, and Palmer of BYU, and Johann Rafelski of the University of Arizona, along with student researchers. Plans for the research were extensively developed at the meeting. Prof. Rafelski had been very active in theoretical work on piezonuclear fusion since late 1985 and strongly urged the active pursuit of this experimental effort at BYU.

D2. Use of Pd, Li, Al, Cu, Ni, Pt under non-equilibrium conditions, was outlined 7 April 1986 - notarized lab notebook page

Prof. Jones's brief notes from the April 7, 1986, meeting (available on request) record that the metals aluminum, copper, nickel, platinum, palladium (because it "absorbs hydrogen readily"), and lithium were discussed as prime candidates for the process. The importance of non-equilibrium conditions was discussed; in particular, "shocked hydrides" and "electric discharge" were considered. These notes were notarized that day by Lee R. Phillips, a notary and BYU attorney, showing the importance attached to these ideas by the physicists present.

D3. Geophysical evidence for cold fusion was sought in the scientific literature as early as April 1986

On April 13, 1986, Prof. Palmer noted in his logbook a number of fusion reactions to be studied, including the deuteron + lithium reaction. (On March 18, he had noted the high amounts of sodium and lithium in magmas; these later became ingredients in our electrolyte solution, commonly known as "Mother Earth Soup".) On April 16, he records the findings of a paper by the Russian physicists B.A. Mamyrin, L. V. Khabarin, an V. S. Yudenich [Dokl. Adad. Nauk. SSSR, 237: 1054 (1987)] in which they report excess helium-3 found in various metals. This paper was encouraging to us, but we were surprised that no follow-up work was recorded in the literature.

D4. Electrochemical cell built and measurements taken beginning May 1986

On May 22, 1986, our first electrochemical cell for "electrolytic infusion of hydrogen into metals" was built (see Prof. Palmer's logbook) and on May 23, D_2O (heavy water) was added. Using a sodium-iodide detector, we looked first for gamma rays from proton-deuteron fusion, and found on May 27 that the foreground rate when the cell operating was slightly higher than the background rate when the cell was not operating, but the result was not statistically significant.

In June, we developed another means of loading hydrogen isotopes into metals, using pressurized gases, and added a neutron detector.

D5.. Work on a highly sensitive, energy resolving neutron detector was begun in 1986, since neutrons of the correct energy are a sure indicator of nuclear fusion

Throughout the summer of 1986, work was done on the neutron detector, while different electrolytes were tried, including the addition of NaOH or H_2SO_4 to D_2O and the addition of "impurity salts" of various metals. We also tried loading the cathode with deuterium gas before beginning the electrolysis (see, e.g., 10 September 1986 entry). By September 3, 1986, we saw a foreground minus background rate of about $5x10^{-3}$ in the neuron counter, but the result was neither not consistently repeatable. However, this rate proved to be consistent with the rate obtained in later work when the neutron counter system had been dramatically improved. As the Fall 1986 school term began anew, we concluded that in order to make progress in our work we had to first improve the neutron detector. Bart Czirr and Gary Jensen continued this work. Some of the effort went into trying to find suitable hydrogen-rich, inorganic scintillator. While this work continued, Dr. Jones pursued muon-catalyzed fusion research.

D6. Student papers presented on piezonuclear fusion experiments in March and April 1988

In January, 1988, Prof. Jones organized a student research class along with Prof. Palmer and Prof. Larry Rees. Cold or piezonuclear fusion was one of the principal research topics, pursued by students Paul Dahl and Paul Banks. Both wrote term papers on the topic. On 12 March 1988, Paul Dahl presented an oral paper at the Spring Research Conference of the BYU College of Physical Sciences and Mathematics; his paper was entitled "An Experimental Investigation of Piezo-nuclear Fusion." On 25 March 1988, we prepared some deuterided metal samples, which we sent to Harmon Craig of the University of California at San Diego, for helium and tritium analysis. These examples were later sent to Al Nier of the University of Minnesota, but analysis had not been completed as of 30 March 1989 as our paper for Nature neared completion.

D7. Further experiments planned, research program set out and pursued vigorously from August 1988

In August 1988, the decision was taken by the scientific team to vigorously pursue experimental cold fusion research. In particular, Prof. Jones' logbook records that a fusion group meeting took place on 24 August 1988, and that this matter was aired. We decided that both gamma and neutron detectors would be used. Since energy applications for muon-catalyzed fusion appeared remote, we decided to place particular emphasis on our cold/piezonuclear fusion research program. This decision followed work in early August by Prof. Jones in which he outlined a paper on the subject. His intent was to include a discussion of piezonuclear fusion research in his paper, for publication in the proceedings of a muon-catalyzed fusion workshop previously held in Florida in May 1988, as recorded in his logbook entry dated 9 August 1988. (Prof. Jones is an editor of this Proceedings, which is publication no. 181 of the American Institute of Physics.) However, during a visit to Provo on 15-16 August 1988, Prof. Rafelski dissuaded Jones from including this work in his paper but rather encouraged more experimental studies first. Dr. Jones also discussed the BYU work on this fusion process and his intentions to emphasize cold/piezonuclear fusion studies with Dr. Alan Anderson and Dane Chapman in August and early September 1988. Our group has vigorously pursued its experimental cold fusion research at BYU since May 1986.

D8. Publishable results obtained in 1988-1989

In August 1988, we did gamma-ray studies, using the sodium-iodine detector easiest set up. As before, we saw only non-significant hints of gamma production in our 3 inch sodium iodide counter, so we decided to concentrate on using the neutron spectrometer, which was fully conditioned for use in late 1988. Our first studies with this spectrometer were done using titanium, palladium, tantalum, nickel, aluminum, iron, and lanthanum. We also used several methods of loading deuterium into metals, including the original electrochemical method. Thus, we performed anew the experiment which we had started in May 1986, namely electrolytic infusion of deuterium into metals, but with a much-improved neutron detector. Of these experiments, Paul Palmer records: "Steve [Jones] and Bart [Czirr] have set up experiments exactly as we did a year or so ago and looked for fusion-generated neutrons in Bart's liquid-scintillator, low-resolution spectrometer.... As in the previous work, the results were tantalizingly positive." Within a few weeks, the results had

reached a statistical significance of over five standard deviations. We also found correlations between tritium detected in Hawaii and volcanic eruptions there, in agreement with expectations that piezonuclear fusion occurs in the earth. We decided in early February to publish our results.

E. Discussions with scientists at other institutions (1986-1988)

Our work in this field has been communicated to a number of scientists outside of BYU in the 1986-1988 period, to name a few : Harmon Craig (University of California, San Diego geophysicist), Al Nier (University of Minnesota), Alan Anderson (Idaho Research Software), Gus Caffrey (Idaho National Engineering Laboratory), James Cohen, Mel Leon, Jim Bradbury, Richard Maltrud, Mike Paciotti (all of Los Alamos National Laboratory), Russell Kulsrud (Princeton Plasma Physics Laboratory), Archie Harms (McMaster University), and Mike Danos (National Bureau of Standards).

III. Scientific Contacts with University of Utah Researchers

A. Steven Jones reviews proposal by Pons and Fleishmann at request of DOE, 20 September 1988

According to Prof. Jones' logbook, he reviewed a proposal by Profs. Stanley Pons and Martin Fleischmann on 20 September 1988, entitled "The Behavior of Electrochemically Compressed Hydrogen and Deuterium." The proposal was sent to Prof. Jones by Ryszard Gajewski, director of the Division of Advanced Energy Projects of the Department of Energy. Dr. Gajewski had funded Jones' work on cold nuclear fusion (including muon-catalyzed fusion) since 1982, and his specific work on electro-fusion since May 1986. For his part, Dr. Jones has reviewed about eight to ten proposals relating to cold nuclear fusion, his primary field of research. The cover letter with the proposal said nothing about declining to review the proposal if the reviewer was doing related work. Indeed, most of the proposals which Dr. Jones is asked by the DOE to review related closely to his active research on cold nuclear fusion, including muon-catalyzed fusion. The cover letter did specify that the reviewer agrees to "use the information contained in the proposal for evaluation purposes only." This Jones accepted and acknowledges that he has abided by this agreement. The development of the project at BYU outlined above, including the use of electrochemical cells since May 1986, shows that Brigham Young University was conducting research in cold fusion, including the use of electrolytic cells and deuterium-gas loading, long before the review of the University of Utah's proposal at the request of the Department of Energy. We adhered to our on-going program in a straightforward way, despite the unfounded accusations which circulated in the media in 1989 following the press conference of Drs. Pons and Fleischmann.

B. Jones offered to cooperate with Pons and Fleischmann

Prof. Jones recommended that the University of Utah's proposal be approved, despite his unresolved reservations about the theoretical underpinnings. He also suggested to R. Gajewski that he inform Pons and Fleischmann that Jones has been doing related work on cold fusion since 1986 and that perhaps a cooperative effort between the nearby universities (BYU and University of Utah) would be desirable. Jones pointed out that the techniques of the two efforts (e.g. neutron detection at BYU and calorimetric measurements at the University of Utah) were complementary and that the research effort could be benefitted by cooperation.

B1. Pons responded with telephone call December 1988

Dr. Gajewski did inform Pons of the proposed cooperation, who in turn called Jones in (about) December 1988 to discuss the matter.

B2. Jones offered use of neutron detector

In ensuing contacts, Pons requested written information regarding the neutron spectrometer which had been developed at BYU. Jones mailed him this information and offered to allow Pons to use the operating neutron spectrometer at BYU. Pons seemed pleased with the offer.

B3. Pons and Fleishmann visited Brigham Young University laboratory, 23 February 1989

Finally, on 23 February, 1989, Pons and Fleishmann came to BYU to visit Jones and his colleagues in the BYU

Underground Laboratory. Pons and Fleishmann were shown the neutron spectrometer and the neutron-energy spectra which it produced, including calibration and actual data distributions. In particular, we openly pointed out the significant fusion neutron signal observed in our data. We also discussed some of our geological evidence for cold fusion (tritium in volcanic gases). In the exchange of information, Fleishmann showed us one of their electrochemical cells, although he indicated that this particular one was one that did not work. We invited them to bring their (working) apparatus to BYU to verify its operation with our neutron spectrometer. They agreed, and the date of 26 February was set for the test.

B4. Researchers agreed to work toward simultaneous publication

Over lunch at BYU that day (23 February 1989), Jones told Pons and Fleishmann that the BYU group was preparing to publish their data and offered to let them publish simultaneously. Dr. Jones reports that when he made the offer to allow the University of Utah researcher to publish simultaneously with the BYU report, he was attempting to establish an open and cooperative relationship. The University of Utah researchers did not come back to the BYU laboratory to test their equipment on 26 February as agreed. Rather, they explained that morning (via telephone) that a graduate student had had to travel to a funeral, and said that they would plan to come at the end of the week. But they did not come then, either. Subsequently, a meeting was proposed by University of Utah President Chase Peterson for 6 March 1989, to be held at BYU with the chief scientists and Presidents of the two universities present.

IV. Contacts Between University Administrators

A. Telephone discussion between President of University of Utah and Provost of Brigham Young University, 3 March 1989

On Friday, March 3rd, the President of the University of Utah called the Provost of Brigham Young University. He made some observations about the significance of cold fusion research going on at both universities, and some of the complexities surrounding the project. He then asked for a meeting with top university administrators and chief scientists involved in the projects as soon as possible. A meeting was scheduled for the following Monday.

B. Meeting between Brigham Young University and University of Utah administrators and principal scientists at Brigham Young University, 6 March 1989

On Monday, 6 March, University of Utah president (Chase Peterson), his vice-president for academic affairs (Joseph Taylor), and the two principle scientists (Drs. Pons and Fleischmann) involved in the cold nuclear fusion experiment at the University of Utah, arrived at 9:00 A.M. to begin the scheduled meeting. Brigham Young University participants in the meeting were the president of the university (Jeffrey R. Holland), the Provost and academic vice-president (Jae R. Ballif), the associate academic vice-president responsible for research (LaMond Tullis), and the principal scientist who directs Brigham Young University's cold fusion experiments (Dr. Jones).

Before the meeting, the president of the University of Utah met separately with the president of BYU and his provost to discuss the agenda. It was agreed that the University of Utah's president could pursue his agenda so long as it included a brief historical summary of the research done at BYU.

President Chase Peterson of the University of Utah first explained how wonderful an invention practical cold nuclear fusion would be. He also said that the large monetary proceeds from said invention could be extremely valuable to the University of Utah. Dr. Jones then held up a small flashlight and stated a strong cautionary note that he would be extremely surprised if enough power could be generated by the process to power even a flashlight in the foreseeable future, and that he could not see in any case how the proceeds from the invention could be vouchsafed for the University of Utah. Jones then reviewed the history of the BYU research on cold fusion (at the request of Academic Vice President Ballif). He described much of the history given above. In particular, Jones showed a notarized page from his own logbook dated (and notarized) 7 April 1986, demonstrating that the metals palladium, platinum, nickel, lithium, copper, and aluminum were particularly enumerated for the BYU research on cold/piezonuclear fusion on that date. He also showed copies of pages from Paul Palmer's notebook that demonstrate unequivocally that experimental research using electrolytic infusion of hydrogen into various metals began at BYU on 26 May 1986, 2 ? years before we learned of the University of Utah work in this area, with the first positive hints of cold nuclear fusion by this process presenting themselves on 27 May 1986. None of these dates were questioned, nor were there any questions about the proposal-

review process involving Dr. Jones. They did not allege at that time that the BYU group had pirated any ideas from their research. After Dr. Jones' review of detailed documents showing the BYU research over the years, Utah President Peterson turned to BYU president Holland and commented on the remarkable coincidence that such similar research had sprung up independently at the two universities. This met with general agreement.

Then the meeting shifted to a discussion of releasing the information to the public. The University of Utah researchers stated that they would prefer to have up to eighteen months to quietly pursue their research before announcing it. Dr Jones stated that he had been funded on the research in question since May 1986, that he had positive results, that he felt obliged under DOE grant to publish his results. Furthermore, the DOE funding agent (Dr. Gajewski) had encouraged him to go ahead with a publication on the experimental work to complement his earlier theoretical paper. In particular, Jones displayed his abstract for an Invited Paper to the Spring Meeting of the American Physical Society of 2 February 1989, which states in Part: "We have shown that nuclear fusion between hydrogen isotopes can be induced by binding the nuclei closely together for a sufficiently long time, without the need for high-temperature plasmas.....We have also accumulated considerable evidence for a new form of cold nuclear fusion which occurs when hydrogen isotopes are loaded into various materials, notably crystalline solids (without muons). Implications of these findings on geophysics and fusion research will be considered."

The University of Utah contingent expressed great concern about Jones' speaking at the May meeting in Baltimore. In particular, University of Utah President Peterson suggested strongly that it would be desirable for Jones not to give the talk. Dr. Jones replied that he was shocked that Pres. Peterson would suggest that he give up an invited APS-meeting talk on the BYU work, and Pres. Peterson finally agreed that he would not ask Jones to cancel his talk. Instead, it was agreed that the two groups would submit papers SIMULTANEOUSLY and quickly (in about three or four weeks time) in order to have the papers accepted and hopefully published before Jones' scheduled talk on May 4, 1989. It was also agreed by all that no public disclosure of the research would be made by either group prior to the simultaneous submission of the papers. In keeping with this understanding, Jones said that he would cancel a previously scheduled physics department colloquium at BYU, set for 8 May (two days later), and he did so. Jones also cancelled a talk by a graduate student (Stuart Taylor) on the BYU cold fusion research scheduled at the BYU Spring Research Conference on 11 March 1989, in order to strictly adhere to this agreement.

In subsequent discussions between Jones, Pons, and Fleischmann, it was agreed that the precise day for the joint submission would be on 24 March 1989. On 21 March Dr. Pons called Dr. Jones and the joint submission date of 24 March was re-confirmed. Dr. Pons indicated that the University of Utah paper was ready but assured Jones that it would not be submitted earlier than 24 March. No mention whatsoever was made of the University of Utah press conference held on 23 March 1989, one day prior to the agreed date for releasing the information jointly, or of the University of Utah paper on cold fusion already submitted on 11 March 1989, to the Journal of Electroanalytical Chemistry by Pons and Fleischmann.

C. Agreements from 6 March 1989 meeting

After an extended discussion of what might be done to accommodate the interests of the University of Utah delegation, it was agreed by all present that:

C1. Simultaneous publication

Scientists at Brigham Young University and the University of Utah would prepare and submit simultaneous publications to the same journal.

C2. Publication prior to APS meeting (May 1989) where Jones was scheduled to speak

Every effort would be made to submit simultaneous publications prior to the American Physical Society Meeting, even though this would be difficult in the short time available. It was agreed that publication in the most prestigious physics journals would be pursued first, but if that could not be accomplished in time, the papers would be submitted to another journal. It was agreed that if necessary journals outside the field of physics would be considered including simultaneous publication in a chemistry journal. Dr. Jones contacted George Miley regarding possible publication of these two paper in Fusion Technology as well as an editor of Nature, for he had previously published papers on muon-catalyzed fusion

in these major journals.

C3. Exchange of preprints

The scientists would exchange papers after they were completed.

C4. No further public comments on results of research until papers submitted

No further public announcements of the results of either teams' research would be made until after the papers were submitted for publication. Brigham Young University scientists had a department colloquium scheduled later in the week to discuss their research. Jones volunteered to cancel the presentation and did so following the meeting at BYU on March 6, 1989.

V. University of Utah Press Conference and Subsequent Events

On 22 March 1989, the BYU group had calls from people at the Department of Energy about a press release announcing a 23 March University of Utah press conference. It stated that net energy-producing cold nuclear fusion had been achieved at the University of Utah, and that a reviewer of the proposal had confirmed the result! We were shocked and disappointed by the announcement and communicated these feelings to Chase Peterson and James Brophy at the University of Utah. For example, on 22 March BYU Professor Grant Mason, Dean of the College of Physical and Mathematical Sciences, spoke to Dr. James Brophy, University of Utah Vice President for Research, and expressed to him that if the press conference were held, we at BYU would interpret this as a violation of the agreements between the two universities. His words were that we would interpret such a press conference "as a stab in the back."

The University of Utah press conference was held (despite our protestations) on 23 March 1989. No mention was made of the cold fusion research at BYU. In fact, a question was asked at the University of Utah press conference: "Is this going on any place else, or is this the kind of process that is currently being developed by anyone else?" to which University of Utah Vice President of Research James Brophy replied: "Let's see, I'll answer it and then perhaps you can . We're not aware of any such experiments going on." It was also stated that the University of Utah paper on their work had already been submitted, although they did not say to which journal. This was also a great shock to us at BYU. After learning of this, we could not see why we should wait until the next day to send our paper to Nature, so, after the press conference at the University of Utah, we sent our paper to Nature. We have received considerable criticism from University of Utah persons for not going to the airport to meet them on 24 March, to send our papers off together. However, it was verified to us on 24 March that Pons and Fleischmann had indeed submitted their paper prior to 23 March; their preprint entitled "Electrochemically Induced Nuclear Fusion of Deuterium" contained this statement on the title page: "Submitted to Journal of Electroananalytical Chemistry March 11, 1989." Thus, the University of Utah paper was submitted prior to 24 March, although we are given to understand that a paper on the subject was also submitted on 24 March to Nature. It is noteworthy that our paper to Nature was published (April 1989, 338:737),, while the P/F paper was not published in Nature after all.

There remains one final area to be recorded in this effort to lay out the facts. Numerous allegations and insinuations have been made to the effect that Dr. Jones pirated the idea of cold fusion in an electrochemical cell or some unspecified ideas from the University of Utah work based on his review of their proposal. For example, such insinuations appeared in a front page article of the Deseret News on 2 April 1989, quoting persons from the University of Utah. Similar accusations were made to officials at the Department of Energy and to scientists at Los Alamos National Laboratory in New Mexico.

On or about 14 February, University of Utah attorney Norm Brown spoke to the BYU attorney Lee Phillips and suggested that Jones had pirated ideas from his review of the University of Utah proposal. This was reported to Jones who reported the allegation to the DOE funding agent Dr. Ryszard Gajwski. Dr. Gajewski then questioned Dr. Pons about this. Dr. Pons apologized for the insinuations of the lawyer both to Dr. Gajewski and directly to Dr. Jones on or about 21 February 1989. We know of no further accusations or insinuations of wrongdoing against Dr. Jones until 10 March 1989, when Dr. James Brophy made allegations of this kind to Prof. John Lamb of BYU. During the week of 14 March 1989, Dr. Pons made general accusations against Jones to Dr. Gajewski, as reported to Jones by Dr. Gajewski.

We have provided evidence from logbooks and other sources that demonstrates that these unsubstantiated allegations are false. When the University of Utah proposal becomes available through the Freedom of Information Act, it will be completely clear, if it is not already, that our work was conducted independently of theirs. (According to agreement with the Department of Energy, BYU retained no copy of the proposal following the evaluation.) Meanwhile, we have opened our logbooks and other documents to public view; copies are available upon request from the BYU Department of Physics and Astronomy.

Jones reported: "A few weeks after the press conference at the University of Utah, I saw Martin Fleischmann in Erice, Italy for the first time since the March 6 meeting. He took me outside the breakfast room and acknowledging that his March 23rd press conference had been "unfair" to us at BYU. He did not suggest that we had driven him to this action. Rather, he told me that administrators at the University of Utah had pressured him to have the press conference. Note that no press conference on "cold fusion" was ever held at BYU. "

We had not agreed to join in a media circus with the University of Utah, which is one of the main reasons we declined to go on March 24 to the SLC airport to send off our paper with the P/F paper (we were told that the press would be there). In addition, at the March 23rd press conference at the University of Utah, it was announced that P/F had recently submitted a paper, before their press conference. So we simply faxed our paper to Nature without fanfare, in such a way that it would have a March 24 submission date. That someone from the U. Utah did go to the airport and indeed waited for BYU to show up - with the press there - shows clearly that they had understood that there was an agreement for parallel submission of papers and that they knew very well of the BYU work. However, they had already submitted their paper on March 11 without informing us. And at the press conference, Dr. Brophy of the University of Utah answered a question about whether any such research was going on elsewhere thus: "let's see, I'll answer it and then perhaps you can. We're not aware of any such experiments going on."

It would be grossly unfair to cast blame on the BYU group these actions by persons from the U. Utah or for the press conference held there, or for the public statement made by Brophy a few days later that the BYU research "confirmed" the P/F work, which statement was terribly misleading.

Jones reported: "During the May 1989 meeting at Sante Fe on Cold Fusion, I approached Dr. Brophy of the University of Utah and expressed my disgust at his allegation (made to BYU Prof. John Lamb, BYU research director, in early 1989) that I had stolen the P/F idea based on my review of their proposal. He told me he no longer believed that."

Addenda - Extracts from early BYU publications on cold fusion.

The following is extracted from a paper submitted in 1985 and published in 1986, on cold/piezonuclear fusion, by Clint Van Siclen and Steven E. Jones:

"It is interesting to consider whether piezonuclear fusion within the liquid metallic hydrogen core of Jupiter can account for the excess heat radiated from the planet. This excess is equal to about one and a half times the energy received from the sun. . . Assuming a metallic hydrogen core of radius 4.6 X 10^9 cm, 189 fusions per cm^3 The following is extracted from a proposal submitted by J. Bart Czirr of Brigham Young University, who performed research on cold fusion with BYU Professors Paul Palmer and Steven E. Jones:

"The present [neutron] detector with improved resolution will find application in several diverse fields, including:

Magnetically confined fusion plasma temperature measurements for d-d and d-t reactions, muon-catalyzed fusion experiments, other cold-fusion experiments, low intensity source measurements requiring good discriminating against background radiation, radioactive source spectrum measurements utilizing (alpha, n) reactions or spontaneous fission, and measurements of the neutron-neutron cross section through the negative-muon/deuteron reaction.

Experiments are currently in progress at Brigham Young University to search for evidence of electron-catalyzed fusion in metals containing deuterium atoms. A neutron spectrometer would provide an important diagnostic tool for the detection of 2.5 MeV neutrons from d-d reactions taking place in these experiments. [emphasis added]

This detector is designed to fill a gap in existing technology for neutron spectrum measurements and permit a broad

range of future experiments. The list above only represents a portion of the potential applications. (J.B. Czirr, SBIR Phase II Proposal, May 14, 1986. See also, DOE SBIR grant, number DE-AC02-85-ER80289.)

The following is a published abstract for a talk presented publicly by BYU student Paul Dahl at a conference held at BYU in March 1988. It demonstrates our active research in this research area a year before the Pons/Fleischman press conference, and long before we heard of them or their research:

"AN EXPERIMENTAL INVESTIGATION OF PIEZO-NUCLEAR FUSION.
P.A. Dahl, P.S. Banks, E.V.Sheeley, E.P. Palmer, S.E. Jones,
Department of Physics and Astronomy, Brigham Young University,
Provo, Utah 84602.

Excess helium-3 and tritium gases have been observed in volcanic emissions as well as in some metals. Independently of these results, theorists Rafelski and Muller suggested to us that excited HD (and by inference D_2) molecules might undergo fusion without the need for stellar temperatures to form ^3He (and tritium), in analogy to the muon-catalyzed fusion process. We are therefore motivated to study the possibility that fusion may occur at a measurable rate in the earth's crust and in metals wherein the fusion of hydrogen isotopes is facilitated by their dense packing amongst surrounding ions. To test this piezonuclear fusion hypothesis, we will prepare deuterated metal foils, subjecting some to high pressures as found deep in the earth. Then the growth of helium-3 and tritium in the foils will be evaluated."

Finally, from a copy of the original log book kept by BYU Prof. Paul Palmer to demonstrate early work on cold fusion at BYU. In particular, these log book entires show that the first cold fusion experiments at BYU were performed in May 1986.

Mar 13 1886 Source of volcanic heat.

Colloquium yesterday by Steve Jones of BYU physics set me thinking. He talked of muon catalyzed cold fusion — among other things such as quark search and electron-catalyzed fusion of HD molecules. He talked of spontaneous fusion under pressure (low) and catalyzed fusion (high).

$$H + D \rightarrow {}^3He + \sim 6\ MeV \quad (\gamma\ \text{below.})$$

Well, when earths sedimentary material at a continental margin gets pulled down in a subduction zone at a plate boundary, fusion could take place as the pressure increased.

<SNIP>

To measure all this, measure the ^3He that outgasses from the lava! Simple. These data must be available. The ratio of H to ^3He that outgasses could allow computation of the fraction of spontaneous fusions per average water molecule.

Perhaps the rock catalyzes the reaction! Temperature separates H and D from water and even oxygen might catalyze.

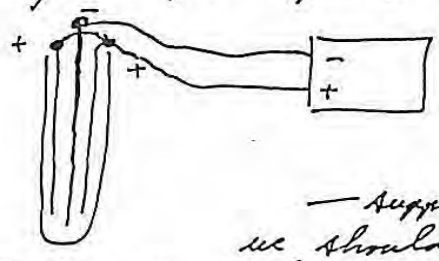
May 22 1986 Electrolytic infusion of hydrogen into metals

We constructed an electrolytic cell in a test tube to try to get hydrogen into metals.



Used a solution of HCl in water. We used copper cathode (−) and nickel anode (+) and ran enough current through to get bubbling at the electrodes. — supposedly, if Cu behaves like Fe, we should get H in the metal.

After 8-10 hrs, a heavy green coating built up on cathode(−) that flaked off when dry. The cathode was nickel plated underneath in a spotty grey-black silver coating. There was green gelatinous stuff in liquid.

We put this strip which supposedly contained hydrogen and deuterium (in the normal concentration for D_2 of .016 %) around the crystal of a gamma spectrometer. We counted background for 1200 sec and copper strip for about — ~ 2400 sec I believe.

May 22 1986 (cont.) Electrolytic infusion of H.

The results were completely inconclusive. The rate with the hydrated sample was 10% ± 7% greater than background. The count on the background was too short but the equipment was needed for other purposes. As Bart said — you wouldn't bet on cold fusion on the basis of these results — but neither would you bet against it.

We don't know if we had any H in the copper. We are going to weigh it and bake it, but that is of doubtful validity because of oxide formation and surface contamination effects.

May 23, 1986 Electrolytic cell using D_2O.

I rigged up the same cell as before but used 10% D_2O, sulfuric acid, and distilled water with copper anode and cathode. I ran it with 200 mA current and approx 1.5 V across cell. Hydrogen came off the cathode in small bubbles. Ran from ~ 10:00 AM

Bart suggests we use palladium as the metal because we know it has the ability to let H diffuse through it readily. It should work fine.

Ran cell 4½ hrs at 200 mA, then cut to 100 mA at 3:00 PM

132) Another testimony

Ludwik Kowalski (3/9/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

After posting the historical testimony of Steven Jones (item #131) I realized that the recent article of Martin Fleischmann is also worth posting here. As many might remember, Fleischmann and Pons were the first to announce the unexplained excess heat, and to claim that it was generated through a nuclear process. Unfortunately, this was done via a press release (see details in item #131) rather than through a publication in a pear review paper. The photo of Fleischmann shown below was taken during a break between two sessions of the 10th International Conference on Cold Fusion. The text that follows was extracted from an article that Fleischmann published in a journal called "Accountability in Research" *(*2000. 8: p. 19). The entire article, entitled "Reflections on the Sociology of Science and Social Responsibility in Science, in Relationship to Cold Fusion" can be downloaded from the library at www.lenr-canr.org. Let me add that Stanley Pons, who worked with Fleischmann, was not at the conference. People said he left research many years ago.

Extracts from Fleischmann's paper

"Reflections on the Sociology of Science and Social
Responsibility in Science, in Relationship to Cold Fusion;"
Accountability in Research*,* 2000. 8: p. 19.

. . . Realization that models of electrolyte solutions had to be based on the Q.E.D. paradigm inevitably focused my attention again on the Pd/H and Pd/D systems. I had realized since the end of 1947 that these were the most extraordinary examples of electrolytes....... The question of whether one could induce nuclear reactions became more clearly-defined at the end of that decade [1960s]. Work on the isotopic separation of H and D showed that it was necessary to assume that the H and D present had to be modeled as many-body systems in order to explain the macroscopic behavior . . . In the early 1980's Stan Pons and I started a number of collaborative projects. ...... We decided that the project not only had to have a 'hidden agenda', it had to be totally hidden. This was all the more necessary because the military applications of any positive outcome of the research were not at all clear. ...... The overall structure of the problem had become reasonably clear by the summer of 1988. We were observing the generation of heat in excess of the enthalpy input to the cells, and far above that commensurate with the generation of tritium and neutrons predicted by measurements on 'hot fusion.' Moreover, the excess enthalpy was far beyond that which could be attributed to any parasitic chemical reactions.

= =

I would be very happy to append M. Fleischmann's comments on what S. Jones wrote in the unit #131. On the other hand, I can understand his reasons for not commenting on political events of 1989-1990 at this time. So let me show how Peter Hagelstein, from MIT, summarized these events in "A Student Guide to Cold Fusion." This recently published document (authored by Edmund Storms) is avaialble over the Internet at http://www.lenr-canr.org. Less than

a year ago, Hagelstein, who has also been an important player in the field if cold fusion, wrote:

“It Started in 1989 . . .

Many of us recall the controversy surrounding the announcement of claims of observations of fusion reactions in a test tube that were made in 1989. At the time, these claims were greeted with considerable skepticism on the part of the physics community and the scientific community in general.

The principal claim of Pons and Fleischmann

The principal claim of Pons and Fleischmann in 1989 was that power was produced in palladium cathodes that were loaded electrochemically in a heavy water electrolyte. The evidence in support of this was a measured increase in the temperature in the electrochemical cell. There was no obvious evidence for nuclear reaction products commensurate with the claimed heat production. Fleischmann speculated that perhaps two deuterons were somehow fusing to ^{4}He through some kind of new mechanism.

Rejection by the physics community

This claim was not accepted by the physics community on theoretical grounds for several reasons:

First, there was no mechanism known by which two deuterons might approach one another close enough to fuse, since the Coulomb barrier prevents them from approaching at room temperature.

Second, if they did approach close enough to fuse, one would expect the conventional dd-fusion reaction products to be observed, since these happen very fast. Essentially, once two deuterons get close enough to touch, reactions occur with near unity probability, and the reaction products (p+t and n+^{3}He) leave immediately at high relative velocity consistent with the reaction energy released. To account for Fleischmann's claim, the proposed new reaction would seemingly somehow have to make ^{4}He quietly and cleanly, without any of the conventional reaction products showing up, and would somehow have to arrange for this to happen a billion times faster than the conventional reaction pathway. Most physicists bet against the existence of such a magical new effect.

Third, the normal pathway by which two deuterons fuse to make ^{4}He normally occurs with the emission of a gamma ray near 24 MeV. There was no evidence for the presence of any such high energy gamma emission from the sample, hence no reason to believe that any helium had been made.

Finally, if one rejects the possibility that any new mechanisms might be operative, then the claim that power was being produced by fusion must be supported by the detection of a commensurate amount of fusion reaction products. Pons and Fleischmann found no significant reaction products, which, given the rejection of new mechanisms, implied an absence of fusion reactions.

An alternate explanation is proposed

The physicists decided in 1989 that the most likely reason that Pons and Fleischmann observed a temperature increase was that they had made an error of some sort in their measurements. When many groups tried to observe the effect and failed, this led most of the physics community to conclude that there was nothing to it whatsoever other than some bad experiments.

The claim of Jones

A second very different claim was made at the same time in 1989 by Steve Jones. This work also involved electrochemistry in heavy water and the observation of reaction products corresponding to the conventional dd-fusion reactions. The initial publication showed a spectrum of neutron emission that Jones had detected from a titanium

deuteride cathode loaded electrochemically. The response of the physics community was skeptical, as the signal to noise ratio was not particularly impressive. Given the polarization of the physics community in opposition to the claims of Pons and Fleischmann (which were announced essentially simultaneously), the physicists were not of a mood to accept much of any claims that fusion could happen in an electrochemical experiment at all. Jones went to great lengths to assure fellow scientists that his effect was completely unrelated to the claims of Pons and Fleischmann, and was much more reasonable.

Also rejected

Physicists had reason to be skeptical. Theoretical considerations indicated that the screening effects that Jones was relying on were not expected to be as strong as needed to account for the fusion rates claimed. As this experiment could not seem to be replicated by others at the time, it was easy for the physics community to reject this claim as well.

Cold fusion, weighed and rejected with prejudice

Cold fusion, as the two different claims were termed, was dismissed with prejudice in 1989. The initial claims were made near the end of March in Utah, and the public refutation of the claims was made at the beginning of May. It only took about 40 days for the physics community to consider the new claims, test them experimentally, and then announce loudly to the world that they had been carefully weighed and rejected.

Following this rejection, physicists have treated cold fusion rather badly. For example, Professor John Huizenga of Rochester University was selected to be co-chair of the DOE ERAB committee that met to review cold fusion and issue a report. Shortly afterward, he wrote a book entitled Cold Fusion, The Scientific Fiasco of the Century, in which he discusses the claims, the experiments, and the extreme skepticism with which the new claims were greeted. Robert Park discusses the subject in his book entitled Voodoo Science. You can find many places where physicists and other scientists happily place the cold fusion claims together with claims of UFOs and psychic phenomena."

133) Another new name for “cold fusion?”

Ludwik Kowalski (3/19/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

This morning I received a message announcing the next conference (ICCF11). And I see that the term “cold fusion” has been dropped. The new name is CMNS (Condensed Matter Nuclear Science)

> Dear colleague,
>
> It is my pleasure to announce you that ICCF11, the 11th International
> Conference on Consensed Matter Nuclear Science will he held in
> Marseilles, France from October 31 till November 5, 2004.
>
> Registrations are open at : www.iccf11.org Use the some site to the
> highlights of the conference: In addition to the usual format of this type
> of conferences we will have:
>
> 1- An open session at the University of Marseilles, with demonstrations
> 2- A special evening session where we will discuss with economists,
> philosophers, journalists and scientists, the consequences of the
> application of "Cold Fusion" in our day to day life, but also the geopolitical
> and economical changes that might occur.
> 3- The week long meeting will end with a press conference.
>
> I hope to see you in Marseilles
>
> Jean Paul Biberian, Chairman biberian@crmcn.univ-mrs.fr

Going to the conference web page I see an invitation to become a member of the Internationa Society for Condensed Matter Nuclear Reactions. The page has many tabs. One of them leads to FAQs (frequently asked questions). Here are two of them:

Why have you avoided "Cold Fusion" in the name of the Society?

Critics back in 1989 dubbed the science "Cold Fusion" because it was a convenient straw-man to demolish theoretically. The name stuck, but it is misleading. Condensed Matter Nuclear Science is about multiple anomalies and it is unlikely that these can be explained by just one class of nuclear reactions be they fusion or fission. "Cold Fusion" is a widely used name of software and could be a source of confusion.

What is the origin of the name of the Society?

It is difficult to trace the origin but Jones' 1989 paper, Nature 338 p 737 "Observation of cold nuclear fusion in condensed matter" certainly stimulated many similar titles. According to Xing Zhong Li, the

phrase "Condensed Matter Nuclear Science" was suggested at a meeting of the ICCF-9 Advisory Committee and he adopted it as the title for the conference proceedings. Subsequently the title was adopted for the electronic journal as announced at ICCF-10

http://www.rle.mit.edu/phagelstein/.

The Society's name may be abbreviated to ISCMNS. Condensed matter nuclear physics is not a new science. It includes neutron and muon physics, fields which are of interest to CF (but often overlooked).

134 Second Evaluation by DOE?

Ludwik Kowalski
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

This Unit #134 will be used to record what I learn and think about the pending evaluation of cold fusion by the US Department of Energy (DOE). I started composing it on 3/21/04.

Below are extracts from an e-mail message received today (3/21/04). The author is Eugene Mallowe; the message was probably sent to many people interested in cold fusion. Somehow I suspect that what is written below is not true. On the other hand, why would Eugene put his reputation at stake without being certain? The title of the full text of his message is "**U.S. Department of Energy Will Review 15-Years of Cold Fusion Excess Heat and Nuclear Evidence**." It will, most likely, be available at:
www.infinite-energy.com

= = = = = = = = = = = = =

1) The U.S. Department of Energy has made a startling reversal of its past refusal to evaluate with a fresh look the large body of experimental evidence that now supports highly anomalous non-chemical magnitude excess heat phenomena in some hydrogen systems, plus associated nuclear anomalies.

2) The confirmation of the DoE review came first in a draft article by Physics Today science journalist Toni Feder. This draft was circulated to several LENR scientists, critics, and others who gave input to Ms. Feder. New Energy Foundation provided input to Ms. Feder and welcomed receipt of the draft article from her. The article is to appear in Physics Today's April 2004 issue, which should be out by the first week of April.

3) The first popular journal to publish the news of the impending DoE review is, however, the UK-based New Scientist. In its March 20, 2004 issue, which was received in the mail today (3/20) at New Energy Foundation here in Concord, New Hampshire, freelance journalist Ben Daviss reports in a short article in the 'Upfront: News in perspective' section (p.6), that James Decker, deputy director of the DoE's Office of Science, 'has pledged to review evidence from the past 15 years of research in the controversial field.' Daviss also writes, 'The study could be completed by January 2005 and might open up the possibility of funding for cold fusion research projects.'

4)The initiative that helped launch the impending review was a letter to U.S. Energy Secretary Spencer Abraham from MIT Professor Peter Hagelstein, a cold fusion theorist since 1989. ..... It was shortly after ICCF10 that Prof. Hagelstein wrote to Spencer Abraham. .....The door to DoE was evidently further opened by Randall Hekman, who is an MIT graduate (1969), a former judge, and an energy entrepreneur (Hekman Industries). Hekman knows Spencer Abraham and Republican Congressman Vern Ehlers from Michigan, who is a physicist. Ehlers is quoted in the Physics Today article that it is time for a new review 'because there is enough work going on and some of the scientists in the area are from respected institutions.' "

= = = = = = = = = = = = = = = = =

After reading the note of Ben Daviss (see below) I posted the following message on the e-mail list CSAM, at Montclair State University.

“Those interested in social aspects of cold fusion might like to read a just published note shown below. It appeared in the March 20, 2004 issue (page 6) of the British journal New Scientist. The title is "No cold shoulder" and the author is Ben Daviss. At first I thought that the e-mail massage about the forthcoming review of the CF field was a joke but now I believe it is true. It is not yet April 1 to print a joke like this. In my opinion there should be two independent panels, one dealing with fundamental science and another with possible practical applications. I would prefer the US Academy of Science to be in charge with the first issue. Practical applications, if any, are decades away. Making promises which can not be delivere is dangerous. That was one of the mistakes made 15 years ago (on March 23, 1989).

And I think that several months is not enough to conduct a serious study of many claims which may or may not be related. I would give scientists two years and enough money to travel to numerous distant laboratories willing to perform experiments with them. The two major claims are: occurrence of unexplained nuclear reactions and generation of unexplained excess heat. The first should be verified by physicists, the second should be verified by chemists (to show that measured heat can not be explained by chemical reactions or another energy storage mechanism).

= = = = = = = = = = =

NO COLD SHOULDER (by Ben Daviss, 3/20/04)
After being banished by many to the realms of pseudoscience, a review by the US Department of Energy is promising to bring cold fusion back in from the...well, cold. James Decker, deputy director of the department's office of science, has pledged to review evidence from the past 15 years of research in the controversial field. The study could be completed by January 2005 and might open up the possibility of funding for cold fusion research projects.

The pledge was sparked by a letter from Peter Hagelstein of the Massachusetts Institute of Technology, a leading cold fusion theorist, to energy secretary Spencer Abraham an international cold fusion conference in Boston in August 2003. The letter summarized the field's recent progress, which includes a new theoretical framework rooted in the equations that define hot fusion. The theory makes quantifiable predictions that proponents of cold fusion say have been verified experimentally. Insiders say that energy department scientists have also been following results in cold fusion, and laying the groundwork for a review for more than a year "There's so much new, valid scientific evidence that it's high time to take another look," says George Miley, professor of nuclear engineering at the University of Illinois. "I'm hopeful that a fair review will remove any remaining prejudice so research proposals in cold fusion will finally be able to compete on their merits."

= = = = = = = = = = = =

6) I also received the draft of the article of Tony Feder. But it would not be appropriate for me to say anything about it at this time. She is one of the editors of Physics Today and her article about the new situation is going to be published. I will comment on that important article after it is printed, presumably in three weeks. In fact, I will try to turn my comments into a letter to the editor of Physics Today. Will they reject my contribution for the third time in a row? It will depend on who what motivates their deire to address the issue.

7) One might find it useful to read recommendations made by the panel of scientists that conducted the first evaluation (see unit #26). Let me quote from it again:

RECOMMENDATIONS (from the ERAB report, November 1989)

A. The Panel recommends against any special funding for the investigation of phenomena attributed to cold fusion.

Hence, we recommend against the establishment of special programs or research centers to develop cold fusion. **[They did not recommended blacklisting, they did not recommended stopping ordinary support, etc.]**

B. The Panel is sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system. **[In other words, they recognized that their negative evaluation was not the final word.]**

C. The Panel recommends that the cold fusion research efforts in the area of heat production focus primarily on confirming or disproving reports of excess heat. .....Cooperative experiments are encouraged to resolve some of the claims and counterclaims in calorimetry.

D. A shortcoming of most experiments reporting excess heat is that they are not accompanied in the same cell by simultaneous monitoring for the production of fusion products. If the excess heat is to be attributed to fusion, such a claim should be supported by measurements of fusion products at commensurate levels. **[And a lot of new data is now avaialable on accumulation of ^{4}He at the rate of about one atom per 24 MeV of excess heat. In other words, the commensurate products were found but they turned to be different from what was expected. It is nor longer a situation in which there were a "fire" without "ashes."]**

E. Investigations designed to check the reported observations of excess tritium in electrolytic cells are desirable. **[Another recognition of something interesting and important.]**

F. Experiments reporting fusion products (e.g., neutrons) at a very low level, if confirmed, are of scientific interest but have no apparent current application to the production of useful energy. In view of the difficulty of these experiments, collaborative efforts are encouraged to maximize the detection efficiencies an to minimize the background. **[That what Steven Jones was doing in the last 15 years. It is about time that other nuclear scientists evaluate his recent data.]**

THAT WAS WRITTEN IN 1989. I INTERPRET IT AS A CALL FOR A FUTURE INVESTIGATION OF ANTICIPATED NEW FINDINGS.

==========

1) Today's article (3/25/04) in The New York Times (by Kenneth Chang) gives additional details on the pending process. Should I be disappointed? The name of the article, by the way, is "**U.S. Will Give Cold Fusion Second Look, After 15 Years.**" Here are some extracts:

"Cold fusion, briefly hailed as the silver-bullet solution to the world's energy problems and since discarded to the same bin of quackery as paranormal phenomena and perpetual motion machines, will soon get a new hearing from Washington..... Last fall, cold fusion scientists asked the Energy Department to take a second look at the process, and last week, the department agreed..... 'It was my personal judgment that their request for a review was reasonable,' Dr. Decker said. For advocates of cold fusion, the new review brings them to the cusp of vindication after years of dismissive ridicule.

'I am absolutely delighted that the D.O.E. is finally going to do the right thing,' Dr. Eugene F. Mallove, editor of Infinite Energy magazine, said. 'There can be no other conclusion than a major new window has opened on physics.' ..... The research is too preliminary to determine whether cold fusion, even if real, will live up to its initial billing as a cheap, bountiful source of energy, said Dr. Peter Hagelstein, a professor of electrical engineering and computer science at the Massachusetts Institute of Technology who has been working on a theory to explain how the process works. Experiments have generated small amounts of energy, from a fraction of a watt to a few watts. Still, Dr. Hagelstein added, 'I definitely think it has potential for commercial energy production.'

Dr. Decker said the scientists, not yet chosen, would probably spend a few days listening to presentations and then offer their thoughts individually. The review panel will not conduct experiments, he said. 'What's on the table is a fairly

straightforward question, is there science here or not?' Dr. Hagelstein said. 'Most fundamental to this is to get the taint associated with the field hopefully removed.' . . .

Because cold fusion, if real, cannot be explained by current theories, the inconsistent results convinced most scientists that it had not occurred. The signs of extra heat, critics said, were experimental mistakes or generated by the current or, perhaps, chemical reactions in the water, but not fusion. Critics also pointed out that to produce the amount of heat reported, conventional fusion reactions would throw out lethal amounts of radiation, and they argued that the continued health of Drs. Pons and Fleischmann, as well as other experimenters, was proof that no fusion occurred. Some cold fusion scientists now say they can produce as much as two to three times more energy than in the electric current. The results are also more reproducible, they say. They add that they have definitely seen fusion byproducts, particularly helium in quantities proportional to the heat generated.

After a conference in August, Dr. Hagelstein wrote to Energy Secretary Spencer Abraham, asking for a meeting. Dr. Hagelstein; Dr. Michael McKubre of SRI International in Menlo Park, Calif.; and Dr. David J. Nagel of George Washington University met Dr. Decker on Nov. 6. 'They presented some data and asked for a review of the scientific research that has been conducted,' Dr. Decker said. 'The scientists who came to see me are from excellent scientific institutions and have excellent credentials.' Scientists working on conventional fusion said cold fusion research had fallen off their radar screens. 'I am surprised,' Dr. Stewart C. Prager, a professor of physics at the University of Wisconsin, said. 'I thought most of the cold fusion effort had phased out. I'm just not aware of any physics results that motivated this.' “

2) What would I suggest to scientists appointed to investigate cold fusion? **SEEK NOT THE GOLDEN EGG, SEEK THE GOOSE**. In other words, focus on essential scientific questions and not on practical applications which are far away, at best. Promising too much, and too early, was one of the mistakes made fifteen years ago. In my opinion the six most important scientific questions are:

```
a) Is it true that unexpected neutrons, protons, tritons and alpha
     particles are emitted (at low rates) in some LENR experiments?
b) Is it true that generation of heat, in some LENR experiments, is
     linearly correlated with the accumulation of He-4 and that the rate
     of generation of excess heat is close to 24 MeV per atom of He-4?
c) Is it true that highly unusual isotopic ratios have been observed
     among the elements found in some LENR systems?
d) Is it true that radioactive isotopes have been produced in some
     LENR systems?
e) Is it true that transmutation of elements has occurred in some
     LENR setups?
f) Are the ways of validating scientific findings in the areas of
    LENR research consistent with accepted methodologies in
    other areas of science?
```

Several other questions about cold fusion research can be asked but the above six are probably the most important. I think that **a positive answer to even one of these questions** should be sufficient to justify an official declaration that “cold fusion, in light of recent data, should be treated as a legitimate area of research.” The normal peer review mechanisms will then be used to separate valid claims from wishful thinking.

3/27/04

In a message received this morning a friend wrote “I see that Park did not mention the DoE review in his current ‘What's New’." To verify this I went to the APS web site <http://www.aps.org/WN/index.cfm> and I saw that the friend is correct. The piece dated 3/26/04 has nothing about the pending DOE review of cold fusion. Is it possible that Dr. Park knows nothing about it?

But I see something else which is perhaps significant. At the bottom of the first item Park wrote: “Are we about to be exposed? It’s time to come clean: WN has fabricated interviews for years. It gives us full control of a story, and it’s highly addictive. Having no experience at confession, WN turned to a professional, Mia Culpa, for help. ‘It’s best to be indirect,’ she mused, "perhaps you could reveal the truth in a whimsical interview with a fictitious expert. Thanks Mia."

Is this an unrelated joke? Most likely. But it was a big surprize to see the Mia Culpa on the web page consulted to see what the spokesman for APS, and the author of the book “Voodoo Science,” has to say about the pending DOE

evaluation of cold fusion. Why was this evaluation not metioned?

135) From the Salt Lake Tribune

Ludwik Kowalski (3/24/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Yesterday was the 15th anniversary of the infamous press conference at the University of Utah. Not surprisingly, two articles about cold fusion were printed in the Salt Lake Tribune to remember the historical event. These articles were probably written at least a week earlier; the pending DOE initiative would otherwise be mentioned. Here are some extracts. Quoting Steven Jones the author writes: " 'There's really a lot going on that looks very favorable,' Jones said of the field [of cold fusion] today. 'But it's not given a fair chance in the journals.' . . . Jones plans to publish a pair of research papers, as part of the conference record, that involve new thoughts on reactions and evidence of tritium, which he sees as a telltale sign of fusion, in two volcanoes. "

I suppose these are the papers summarized in my unit #113. "In the late 1980s and early 1990s, Jones was able to reproduce what he believes are cold fusion reactions about 15 percent of the time. Today, Jones and company claim to see evidence of charged particles as a product of nuclear fusion up to 80 percent of the time. They also indicate the presence of neutrons about 40 percent of the time. Even the 80 percent figure was still not enough for the top science journals. .....The journal Physical Review C turned down one of Jones' recent efforts because the experiment did not work 100 percent of the time. Another problem: Jones could not offer an explanation for what exactly was happening."

Hmm, interesting. Do the editors of this journal ask authors of all experimental papers about how many unsuccessfull attempts were made before a success? In the past I coauthored many published papers but I do not remember being asked about the number of unsuccessful runs or about the number of repetitions. Why is cold fusion treated differently? Because extraordinary claims call for extraordinary scrutiny. But a success rate of 80%, in my opinion, is already very impressive. Knowing the credentials of the author I would publish the article, if i were the editor.

"These sorts of woes [irreproducibility] have haunted the cold fusion community since the early 1990s. The events of 1989 have essentially stigmatized the field as a whole, said Bart Simon, a sociologist at Canada's Concordia University. 'You can't deny it would have been a different story if it had not been publicized when it was publicized,' said Simon, who wrote the 2002 book, Undead Science: Science Studies and the Afterlife of Cold Fusion. Jones continues his unfunded work with an apparatus that uses deuterium gas. Three labs are working on replicating his latest findings, he noted. Even without funding, Jones continues to set up fusion experiments."

In the second Salt Lake Tribune article the same author writes: " the [cold fusion] episode may be remembered most as a clash between science and capitalism, where science lost." I suppose that in this context the term capitalism refers to those administrators who wanted the golden egg before the goose was born. I hope the new DOE panel will focus on science and not on practical applications. Such applications seem to be much less certain than highly unusual experimental findings. Fortunately, this time, I see no call for massive support of another Manhattan-like project. The cold fusion tragedy probably would not have happened if scientific findings had been announced through peer review papers and not through a sensational press release. That is what I would emphasize, if asked to write a newspaper article about what happened fifteen years ago.

136) What is cold fusion?

Trying to publish a review.

Ludwik Kowalski (4/6/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

What is cold fusion? This question should be answered before an attempt to validate CF claims is undertaken by the DOE. Some people think that cold fusion is generation
of excess heat in electrochemical cells. This is not a good definition. Many hidden effects, for example, parasitic chemical reactions or some kind of storage (as in an electric battery) can produce "excess heat." For several days I was trying to formulate a satisfactory definition of cold fusion; I now have one. I hope it can be useful to those who will be examining CF claims.

Cold fusion is any process in which a nuclear reaction is produced without relying on traditional means, such as particle accelerators, neutron sources, stellar temperatures, cosmic rays or alpha particles.

P.S. insertion (May 5, 2004):

Referring to the above definition Steven Jones, who invented the term cold fusion, wrote to me in private: “I strongly suggest that you re-consider your definition of cold fusion. Consider:

Cold Fusion is: ‘Nuclear fusion which occurs in condensed matter.’

This brings in recent experimental observations of strongly enhanced fusion yields with low-energy deuteron beams on d and Li in metal lattices, as well as the observation of the importance of currents in deuterided metals. The "condensed matter" requirement implies "cold" temperatures without having to say "cold fusion." Note also that fusion includes p,d,t +Z fusion, where Z is equal to OR GREATER THAN ONE. (This includes hydrogen istopes, lithium, and heavier elements.) In short, your definition should include the most important new directions in the field! Note that our original Nature paper (April 1989) was entitled "Observation of cold nuclear fusion in condensed matter." "Condensed matter" is the key to the whole matter, for it enhances the p,d-Z fusion rate... We are still exploring how this trick is accomplished. But it is real!

END of the P.S. insertion

Focusing on excess heat is not the best way to investigate CF. My advice would be to focus on presence or absence of easy to demonstrate nuclear signatures, such as highly abnormal isotopic ratios or the accumulation of ^{4}He at the rate of one atom per 24 MeV of excess heat. Such findings have recently been reported by several CF researchers. They say that CF is no longer "a fire without ashes," as it was characterized in 1989. Is this true? Only highly trained chemists, working in ultra-clean labs, will be able to tell.

Will the DOE appointed panel ask cold fusion experts to perform demonstrations in their presence or will it accept testimony of several teams of scientists who observed accumulation of ^{4}He (and other presumably observed ashes)? Will they ask Steven Jones to repeat several experiments in which the probability of success (to observe neutrons and other nuclear particles) was reported to be 70%? It depends on the mandate assigned to the panel, and on financial means given to it. The idea to investigate resent CF claims is very good but the project could easily degenerate into personal clashes and inconclusive investigations due to insufficient means. Mutual personal accusations between R. Park and E. Mallove (see item 2 below) are totally inappropriate at this time. Park thinks that Mallove is a leader of CF researchers while Mallove thinks that Park is the leader of researchers who categorically reject CF.

I think that both assumptions are wrong. No one is the leader of about 200 top CF researchers, world-wide. No one is the leader of tens of thoudands of scientists, also world-wide, who are very sceptical about CF claims. The first group is loosely organized through yearly conferences, the second has a powerful bureaucracy controlling the tax money. In that sense the situation is highly assymetric. But individual scientists in each group are very similar. Most of them are not extremists and that is why, I think, an honest public dialog is possible. Will those who organize the second review of cold fusion be able to keep the debate scientific? Will they be able to correct assymetries and make sure that the entire process is not derailed by extremists? I hope so.

2) Illustrating poisonous words.

Using the American Physical Society (APS) server <http://www.aps.org/wn/> Robert Park wrote (on 4/2/04): “COLD FUSION: TRUE BELIEVERS SEE DOE REVIEW AS ‘VINDICATION.’ There hasn’t been much to celebrate in the 15 years since the University of Utah held a press conference in Salt Lake City to announce the discovery of ‘cold fusion.’ Although a brave little band of true believers continued to trumpet cold fusion, the band leader was publishing ‘Infinite Energy Magazine.’ That made it pretty hard to take this stuff seriously.” To which Mallove reacted with an e-mail message. It arrived on the same day; and was probably sent to many others. Mallove wrote:

“Dear All: One of the greatest honors that can be bestowed on a scientist is to be attacked by the mental midget, Robert Park, who represents himself as a ‘scientist’ and a spokesperson for the American Physical Society. . . I am happy for the great privilege of being repeatedly disparaged over the years (since 1991) by this buffoon. And Infinite Energy magazine gets free publicity too. As everyone knows, Park is completely out of touch with the now compendious laboratory evidence for low-energy nuclear reactions (LENR - a.k.a. ‘cold fusion’). He has not examined the papers -- peer-reviewed and otherwise, and he damned well knows that. So at some deep level, this regular purveyor of misinformation knows that he is cornered and will die the fool that he is -- for sure on the topic of low-energy nuclear reactions.

I look forward to the day when the vile corpse of Park no longer rattles and confuses the world with weekly doses of misinformation. When will the APS wake up? I hesitated to use the ‘corpse’ metaphor, but Park seems so fond of using it against cold fusion that in this case it is seems highly appropriate. And besides, there may be another oak tree waiting for him...to put him out of his misery in the face of his inevitable doom on the matter of LENR. APS members should be so lucky. But while Park still breathes and rants, they should not continue to allow him to be the anti-science black mark that he represents for the APS. Finally, I categorically deny - of course - that I am the leader of any ‘cold fusion band’! Sincerely, Dr. Eugene F. Mallove President, New Energy Foundation, Inc. (A Nonprofit, 501(c)(3) Corporation) Editor-in-Chief, Infinite Energy Magazine PO Box 2816 Concord, NH 03302-2816 www.infinite-energy.com editor@infinite-energy.com”

I hope that the pending DOE review will not trigger a war of insulting words and accusations. How can an objective evaluation of scientific facts and interpretations be conducted when poisonous bullets are flying in all directions? But who can prevent Park and Mallove from jumping at each other? Would they be able to forget what they wrote about

each other, publicly, in more than a decade? I do not think so. They probably enjoy verbal wars. That is very unfortunate.

3) On March 23, 2004, in a private e-mail message to X, I wrote:

According to today's article about cold fusion in The New York Times the second evaluation will not going to be as detailed as the first one was. Is this correct? I have a slogan to suggest for your meetings. SEEK NOT THE GOLDEN EGG, SEEK THE GOOSE. In other words, focus on essential scientific questions and not on practical applications which are far away, at best. Promising too much, and too early, was one of the mistakes made fifteen years ago. In my opinion the six most important scientific questions are:

1) Is it true that unexpected neutrons, protons and tritons are emitted (at a very low rate) in some LENR experiments?
2) Is it true that generation of heat, in some LENR experiments, is linearly correlated with the accumulation of He-4 and that the rate of generation of excess heat is close to 24 MeV per atom of He-4?
3) Is it true that highly unusual isotopic ratios have been observed among the elements found in some LENR systems?
4) Is it true that radioactive isotopes have been produced in some LENR systems?
5) Is it true that transmutation of elements has occurred in some LENR setups?
6) Are the ways of validating scientific findings in the areas of LENR research consistent with accepted methodologies in other areas of science?

I think that a positive answer to even one of these six questions should be sufficient to justify an official declaration that "cold fusion, in light of recent data, should be treated as a legitimate area of research." The normal peer review mechanisms will then be used to separate valid claims from wishful thinking. Please excuse this attempt to share with you a personal opinion on a subject with which you must now be deeply preoccupied. Feel free to share the above with anybody you wish, or to modify it in any way that can be useful.

4) My review article

In trying to publish my review article about CF I approached editors of several well known US journals. But no sucess so far. Here is what I wrote in an accompanying letter in one of the submissions.

"I am sure that you are aware of the DOE move to review the cold fusion field, as reported in The New York Times (3/25/04). Attached is a review article which, I hope, can be published in ***** . The title is 'Recent cold fusion claims: are they valid?' It is not a paper defending cold fusion claims; it is a paper describing them, no matter what one is inclined to think. Scientifically literate readers are likely to appreciate my short summary of recent claims made by cold fusion researchers.

Some of these claims, such as turning Sr into Mo, or Cs into Pr, without stellar temperatures, are even more extraordinary than the claims made by Pons and Fleischmann. The strange thing is that authors of such reports seem to be reputable scientists associated with prestigious universities and laboratories. Is it a matter of fraud? Is it a matter of self-deception, or incompetence? Is it a matter of progressive degeneration due to the isolation of the field from mainstream science? My article does not try to answer these questions; its purpose is to present a summary of what has been recently reported without taking sides. The subject is interesting no matter what the final verdict of the second DOE evaluation will be.

Like many other science teachers, I am in no position to verify validity of hard-to-accept claims in a specialized laboratory. That is why, as suggested in the concluding section, a new evaluation of cold fusion claims, by an appointed panel of experts, is highly desirable. In writing this I was not aware of the pending DOE review. I am a physics teacher

at Montclair State University. Studying cold fusion was my 2003/2004 sabbatical project, which resulted in the attached manuscript." So far I was not successful; perhaps I will be more lucky with an European journal, such as Nature. That journal is also known for being negative about accepting papers devoted to cold fusion. Why should they be more receptive to my review than American journals? Instead of sending them my article I will firs ask them if they might be interested. Nature has a mechanism for this, it is called pre-submission.

5) Nature

The most impressive part of pre-submitting my CF review article to Nature was the nearly immediate negative reply. It came about ten hours after I approached them. The process of pre-submission consists of pasting information into two text boxes on their web site. The first box is for the letter about the paper; the second is for the opening paragraph of the paper, and for references used in it. In the first box I pasted what was shown in item 4 above (with some modifications). The content of the second box was:

"Cold fusion (CF), presumably discovered 15 years ago, is any process in which a nuclear reaction is produced without relying on traditional means, such as particle accelerators, neutron sources, stellar temperatures, cosmic rays or alpha particles. In 1989, several months after the discovery was announced (through a press release at the University of Utah) a panel of scientists, appointed by the US Department of Energy (DOE), examined the evidence supporting the CF claims. That evidence was declared insufficient. But, as summarized in (1) 'there remain unresolved issues which may have interesting implications. The Panel is, therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system.'

CF became highly controversial and only several hundred researchers continued working on it, worldwide. Most scientists still think that cold fusion is pseudoscience. On that basis editors of many journals refuse to publish papers devoted to CF research. Only a small fraction of scientists is familiar with recent progress in that area. The purpose of this article is to objectively summarize recent findings (2) and to supply references with which I am familiar. The article was triggered by the reported initiative of DOE to review (3,4) cold fusion research. I will focus on four cold fusion claims which are, in my opinion, the most important. As a nuclear physicist, and a physics teacher, I examined some of CF publications and attended one cold fusion conference (5).

1. Huizenga, J. *Cold Fusion: the Scientific Fiasco of the Century*. Oxford University Press, 2nd edition, Oxford, 1993.
2. Cold fusion papers are usually published at specialized scientific conferences. Many of them are downloadable from the library at http://www.lenr-canr.org.
3. Daviss, B. "No Cold Shoulder." *New Scientist*, March 20, 2004, p 6.
4. Feder, T. "DOE Warms to Cold Fusion," *Physics Today*, April 2004, page 27.
5. The Tenth International Conference on Cold Fusion was held in Cambridge, Massachusetts 24 - 29 August 2003. Conference proceedings, in the form of Pdf files, can be downloaded from http://www.lenr-canr.org/iccf10/iccf10.htm "

The reply was short and clear; "Thank you for your enquiry about submitting your paper entitled 'Cold fusion 15 years later' to Nature. I regret that the paper that you describe seems unlikely to prove suitable for publication in Nature, and we accordingly suggest that you pursue publication elsewhere. I am sorry that we cannot respond more positively on this occasion. Yours sincerely Dr Karen Southwell, Senior Editor." I was aware, from browsing, that the rate of acceptance in Nature is about 1 out of 10. On that basis I should have expected a rejection.

137) Another nonsense?

Ludwik Kowalski (4/12/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

In browsing the Internet I found a web site of a team promoting a cold fusion reactor. The arguments are not at all convincing. Do the authors themselves believe in what they are saying or are they fully aware that it just a commercial pitch? I suspect that a con artist directing behind this non-existing project. The URL of the web site is:

http://dspace.dial.pipex.com/brook.farm/fusion.shtml

SUMMARY REACTOR PROJECTS
A specific Reactor design has been developed by a group of eminently recognized scientists during the last fifteen years. Funding for this project has been obtained from STU, a Swedish government funding institution which invests in Hi-Tech projects for development in Sweden. Additional capital investment has also been provided by private Foundations, Institutions and the Inventors.

WHY ARE THEY SO VAGUE ABOUT EMINENTLY RECOGNIZED SCIENTISTS AND ABOUT PRIVATE FOUNDATIONS?

The ultimate aim of the Reactor application is to develop a small portable 500kW power generator based on a new nuclear "cold" fusion reaction. With the prospect of depleted natural energy resources in less than 100 years this invention could replace the totality of the worlds estimated energy demand. The unit can be made small enough to replace a standard car engine or the boiler of a family house. When selling "power-by-the-hour" each unit is expected to produce magnificently high returns. Comprehensive third party computer simulations of the process has shown its feasibility.

COMPUTER SIMULATIONS ARE OF NO HELP IN SITUATIONS IN WHICH NOTHING IS KNOWN ABOUT UNDERLYING PHENOMENA. IT IS LIKE RELYING ON A THEORY THAT DOES NOT EXIST.

There are a number of further applications for this reactor described below.

COLD FUSION REACTOR INTRODUCTION

The Inventors has taken a very close and active look at the spectacular proposals to gain nuclear fusion energy from a body of the element Palladium. However, for scientists it has been known for a long time that this element has unusual properties. By direct information from advanced scientists in USA and Japan we now know that proofs exist that some unexplained reactions occur. For this reason a materials expert has already been engaged in our group who is working with the bulk treatment of the materials in question.

METHOD
Of particular interest is that of the basic concept seen to be extremely useful in treatment of materials, implanting

deuterium into the matrix, and triggering energy releasing events.

NO EVIDENCE IS GIVEN THAT THEY KNOW HOW TO DO THIS.

We keep close collaboration with Japanese Scientists as we hold a patented construction which may be essential in the future development of a reactor type which is known to be of interest to the Japanese. We believe that our patents will be essential for the final development of a working unit to their stated requirements.

CLAIM
It has been claimed lately especially from Japan that it is possible to make energy producing units based on the original idea. In combination with our patents the possibility of a working prototype may be very feasible within a 5-7 years.

AHA, NO WORKING PROTOTYPE, ONLY SIMULATIONS. THE STYLE IN WHICH THIS WEB PAGE IS WRITTEN IS NOT VERY CONVINCING. I WOULD NOT INVEST A PENNY IN THAT REACTOR.

by Marc J. Plotkin
Pure Energy Systems News Service
March 27, 2004

FAIRFAX, VA USA

After fifteen years of wandering in the wilderness, the “cold fusioneers” may finally see their field get the recognition they believe it deserves.

Since 1989, that small but growing band of scientists has persisted in trying to verify the existence of low-energy nuclear reactions, at great personal costs and in the face of overwhelming opposition and ridicule from the mainstream physics community. But now, their persistence may finally be bearing fruit. The New York Times reported on March 25, 2004, that the U.S. Department of Energy has decided to give cold fusion a second look. At a meeting with several top cold-fusion researchers, officials from the Department indicated that given the Matterhorn of experimental evidence that has accumulated over the past fifteen years, a second review was reasonable. The Department’s findings will be presented in December 2004 or January 2005.

Three days earlier, New Energy Times science journalists Steven Krivit and Nadine Winocur have released a 50-page report on the current state of cold fusion. According to this report, almost 15,000 cold fusion experiments have been performed around the world since the field was declared anathema in 1989. In the first years after the initial announcement, experimental results were erratic and inconsistent, often with positive results occurring in only about 10 percent of the experiments. Within the last five years, however, successful replications have been occurring much more frequently. Five years ago, the Fleichmann-Pons effect had been observed in only about 45 percent of the experiments performed. Now, according to Krivit and Winocur, the effect has been reproduced at a rate of 83%. Experimenters in Japan, Romania, the United States, and Russia have reported a reproducibility rate of 100 percent.

This experimental success is due in large measure to more refined methods of measuring excess heat and detecting the signatures of nuclear reactions. Over the years, experimenters have discovered that in order to obtain more robust results, the ratio of deuterium atoms in the electrolyte solution to palladium atoms in the cathode must be above a certain minimum threshold. This is referred to as “loading.” The density of

the electric current passing through the system must likewise reach a certain threshold. More recently, it was discovered that excess heat could be generated faster if the reaction could be triggered in some fashion. In a paper presented at the 10th International Conference of Cold Fusion, held at MIT in August 2003, researchers Dennis Cravens and Dennis Letts presented a variety of methods that could be used to "shock the system," including current-pulsing, radio frequency excitations, and laser stimulation. Actual experiments were carried out at the conference, and the results were manifest for all to see.

According to Dr. Eugene Mallove, editor of Infinite Energy Magazine and a passionate advocate of cold fusion development, the evidence of excess heat and products from nuclear reactions is so extensive as to compel a finding that the cold fusion phenomenon is real. Were it not for Dr. Mallove and others who kept the faith, cold fusion might well have faded from the public consciousness.

When the Department of Energy decided to give cold fusion another hearing, it made no public announcement and did not post any information about its decision on its website. Nevertheless, Dr. Mallove remains confident that once the Department evaluates the evidence in an open-minded and unbiased fashion, it will reconsider its earlier rejection of cold fusion and pave the way for funding of next-generation cold fusion research.

Whether or not cold fusion can be turned into a useful source of energy remains uncertain. But the first step of that 1000-mile journey has been taken. The existence of the phenomenon discovered by Fleischmann and Pons in 1989, then disavowed by the scientific establishment, but subsequently confirmed worldwide in thousands of experiments, may finally be recognized as a revolutionary discovery of science. Cold Fusion may become hot news again.

Here is the ending of the article posted by Charles Choi at the above URL

"I was working at Los Alamos National Laboratory when Pons and Fleischmann made their announcement," Storms recalled. "The laboratory took an enthusiastic interest in the claims and many efforts were undertaken to replicate. Only three were successful, one of these being my effort. Actually seeing the effect is a powerful reason to believe it is real and caused me to continue my research after I retired."

Within a year after the initial announcement, a Department of Energy review decided cold fusion did not bear special federal funding. "The Department of Energy has been the single most important impediment in the development of the cold fusion phenomenon," Storms said.

McKubre, director of SRI's Energy Research Center, told UPI he felt the original Department of Energy review was "premature and hasty, but it couldn't have been avoided. And it really was not that damning if interpreted rationally. The original panelists said they didn't see any evidence to merit special treatment. That was interpreted as a condemnation, which meant no money was made available." In the past 15 years, researchers in universities, government, military and private labs in at least 13 countries have pursued cold fusion, according to New Energy Times. McKubre noted cold fusion results are now more reproducible.

Now, a number of prominent international researchers treat cold fusion seriously, including physics Nobel laureate Carlo Rubbia, McKubre said, adding the U.S. government has provided funding for cold fusion research, albeit through military agencies, such as the Defense Advance Research Projects Agency, and the Naval Research Laboratory -- not DOE.

McKubre said the new review has a target date of January 2005 for reporting its findings, although he said "it seems to

be acted on in the Department of Energy at lightning speed. My guess is it could be done by the end of the academic summer."

Park had no objections to the review.

"The way the system is supposed to work is that everybody is supposed to make their point, that science is not closed," he said.

Charles Choi covers research for UPI Science News. E-mail sciencemail@upi.com

= = = = = = = = = = = = = =

And here is one which is short but very significant. I can say this because I met some of those who are motivated by "results once seen." On 3/29/04 Richard Hull posted this message"

". . . As much as physicists would like to see it all just go away like N rays and polywater, there are just too many folks impressed by the process and befuddled by its capriciousness to just drop it. Results, once seen, even if not replicable on demand, keep a faithful cadre of workers beguiled. (as it should any true scientist.). "

= =

John Harris, like myself, went to the 10th cold fusion conference to learn what about the field. On 3/27/04 he posted a message, under the subject "Cold fusion - Another official look." Here is his messages:
"The tenth conference on cold fusion was held last August in Cambridge. I went up to see what was going on. Here is a quick summary of what I gathered in. Various researchers have by this time accumulated evidence for heat, helium-4, helium-3, and tritium. New to me were reports of quite energetic alphas loose in the system (8 MeV and faster) and energetic protons as well. It was not clear to me whether or not the protons were knocked out of deuterium by the alphas' passage. Fast neutrons are still missing. I don't think anyone has ever assessed the slow neutron population in a PF (Pons Fleischmann) cell.

There was a report of a change in lithium isotope ratios in the cathode, but it was not clear (to me, anyway) if this change could be attributed to reactions or to electromigration. One energetic trend in experimental systems is to thin films, and I had the impression some investigators would like to get away from the electrolysis cell altogether, that is, load palladium (or other metals) with deuterium under pressure rather than electrolytically. It has been found that it helps to stimulate the surface of a deuterium loaded cathode with a low power (semiconductor) laser. There were plots of laser stimulation vs xs heat out.

On the theoretical side, several researchers are still emphasizing d+d, and especially d+d => He-4. Scott Chubb has a helpful paper on the net explaining his and various other theoretical views of this concept. Peter Hagelstein has also created a theoretical basis for this pathway. The problem is that no gamma comes out. The theoretical efforts are aimed at somehow visualizing a way to turn the energy that one would expect to emerge as a gamma into heat instead. Another popular (maybe I should say modish) idea is a sort of triple deuterium reaction system. It actually seems like a pretty clean idea, and there were some experimentalists at the conference who are finding results that would seem to support it. One thing has not changed over the years. Although the umbrella name for the whole enterprise has been changed to "low energy nuclear reactions," or LENR, and there is a nodding recognition that other reactions or processes could be invoked to account for the results, the discussion is still pretty much all about the fusion of deuterium. Many of the conference papers can be downloaded, now, from the LENR site."

= =

Here are two messages I posted on www.MarsNews.com list:

My definition: "Cold fusion is any process in which a nuclear reaction is produced without relying on traditional means, such as particle accelerators, neutrons, cosmic rays, alpha particles or stellar temperatures." Unfortunately the term

"cold fusion" means different things to different people. It is certainly premature to define cold fusion as a practically unlimited energy resource. But that is what most people say when asked to describe CF. I suspect that many disagreements about CF would disappear if its definition were accepted by all antagonists. The main issue today is validity of scientific claims, such as accumulation of He-4 at the rate of about one atom per 23 MeV of excess heat (reported by many teams), and not practical applications. Promissing too much too early was one of the mistakes made in 1989. I hope that the DOE will focus on science and not on applications. Applications would follow naturally after basic scientific claims are recognized as valid.
Posted by: Ludwik Kowalski at April 13, 2004 04:14 PM

* * * *
I am responding to my own message above. Excess heat (at the level of 1 W and less) can be due to non-nuclear causes. Most of us are not qualified to rule out possibilities of some parasitic chemical reactions (already mentioned in 1989 reports) or some electric battery effects (also mentioned by those who criticized cold fusion). That is why direct demonstrations of "nuclear signatures," such as neutrons, protons, tritons and alpha particles is much more convincing. See recent reports of Steven Jones (about neutrons and protons) or the report of Lipson (about alpha particles). These reports can be downloaded from the library at <http://www.lenr-canr.org> Excess heat, if it were reproducible at the level 50 W or more, would be not only very convincing but also very promissing. I have a web site devoted to cold fusion: <http://blake.montclair.edu/~kowalskil/cf/ >

* * * *

At <http://www.prweb.com/releases/2004/3/prweb114697.htm> is an interesting letter **from Tom Bearden to Eugene Mallove**, the editor of Infinite Energy. On 3/21/04, in the second half of his letter ,Tom wrote:

. . . The only conventional way to overcome this ordinary "Coulomb barrier" blockage of fusion at low temperature is to go ahead and use high temperature and the resulting very high ion momentum necessary for some ions to penetrate and overcome the normal Coulomb barrier between themselves and their approaching ions, headed at each other and thus colliding. In short, some collision and formation of the necessary "quasi-nuclei" is achieved by brute force temperature and momenta, for some of the ions on mutual collision courses.

Now consider a "reaction reversal zone" up to a cubic micron in size, where indeed the reactions do run backwards negentropically (due to the production of negative work) for up to two seconds. When reactions are reversed, then the law of attraction of charges can also be reversed. In this special zone, momentarily, now the "reversed Coulomb law" is that like charges attract and unlike charges repel -- for up to two seconds and in zones up to a cubic micron in volume. So up to a few dozen billion ions and molecules can be involved in reversals of the coulomb barrier into a coulomb attractor.

Interestingly, the difference between a proton and a neutron is merely the orientation of a single quark. Consequently, theorists need to look into the implications at the quark level when two protons are in such a "negative entropy region" with reactions reversed. In that case, the Coulomb barrier is now reversed between the two protons! It is now the "Coulomb attractor" rather than the "Coulomb barrier". It seems the two protons could now certainly attract each other so closely that each does indeed penetrate to the strong force "deep" region of the other (if things were normal). Further, instead of the "deviation aside" of nominal close misses, the reversed Coulomb barrier can convert a near miss into a collision "hit".

It may also be that the strong force of each particle is also momentarily reduced, depending on the extent of reversal action on the gluon forces and on the orientation of the quarks. At any rate, it appears that a "quasi-nucleus" of two H+ ions can form, with the probably "flipping" of one quark in one proton to turn that proton into a neutron, lowering the excitation. That would be the formation of a quasi-nucleus of deuterium. Then as the transient thermodynamic fluctuation reverses in sign and things move back toward equilibrium, the strong force would again resume its strength (much stronger than the now emerging Coulomb repulsion between the two protons). The notion is that the quasi-nucleus of deuterium would just "tighten" into a normal deuterium nucleus, or just a D+ ion.

At least this notion of a reversal of the Coulomb barrier and a reversal of the law of attraction and repulsion of charges,

precisely fits theknown fact that negative entropy, reversed reaction zones do occur and have been experimentally demonstrated by thermodynamicists completely independently of cold fusion experiments. This then lends yet one more powerful argument that cold fusion can and does occur under the proper circumstances, and those circumstances may necessarily include the proven "reversal of reactions" that occur in such thermodynamic reversal zones that experimentally violate the second law of thermodynamics by producing negative work, negentropy, and reversal of the Coulomb barrier into a Coulomb attractor.

In our book, Energy from the Vacuum, Cheniere Press, 2002 we also listed candidate "reversed reactions" that would well occur in such fluctuation zones, and that would yield the experimentally observed alpha particles, tritium, etc. in the experiments. These suggested "reversed reactions" are based on the temporary "reversal" of the law of attraction and repulsion of charges, occurring in one of the thermodynamic reversal zones that have been experimentally demonstrated by thermodynamicists. As is well known, the occurrence of such excess deuterium, tritium, and alpha particles is icommon to a great many of the successful cold fusion experiments conducted in multiple laboratories by many researchers, in multiple nations of the world.

Anyway, let us fervently hope that the DoE gives a very rigorous and very fair review and appraisal of the cold fusion situation. And let us hope they also take into account the very important and pertinent transient fluctuation thermodynamics work and its production of significant "reversal zones", as shown by researchers such as Evans, Searles, Rondoni, Wang, et al.

My comment:
Another possibility is that potential energy curves (plotted against distances) might be more complex than a textbook curve with a single maximum. A V(r) curve, especially in a solid, may have two, or more, peaks separated by local minima. It is conceivable that a local minimum, (or a sequence of minima on the outer side of the coulomb barrier hill) play an important role in cold fusion. Fission isomers, discovered in 1960s, (by Polykhanov?) were explaied in terms of such potential energy minima.

139) Suggestions for the DOE investigators

Ludwik Kowalski (4/25/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

While waiting in suspense for the pending DOE investigation of cold fusion, I would like to speculate about what I might do if I were in charge of the project.

1) By my definition: "Cold fusion (CF) is any process in which a nuclear reaction is produced without relying on traditional means, such as particle accelerators, neutrons, cosmic rays, alpha particles or stellar temperatures." Unfortunately the term "cold fusion" means different things to different people. It is certainly premature to define cold fusion as a practically unlimited energy resource. But that is what most people say when asked to describe CF. I suspect that some disagreements about CF would disappear if the above definition were accepted by all antagonists.

2) Is the so-called “excess heat,” reported by many investigators, real or not? I would not focus on this question, unless the heat were generated reproducibly at the rate of 10 W or more. Excess heat per se is not a signature of a nuclear process; heat generated at the rate of one watt or so can be due to parasitic chemical reactions or to other hard-to-identify effects. The most convincing argument against CF, in the 1989 ERAB report (1), was the lack of evidence for nuclear reaction products accumulating at rates commensurate with excess heat. This argument, according to many cold fusion researchers, is no longer valid. They claim that in some experiments ^{4}He has been observed to accumulate at the rate of about one atom per 23 MeV of excess heat. This claim would be the first to investigate on my agenda.

3) In practical terms I would proceed as follows. First I would select a research team claiming to be able to conduct the experiment. The Japanese team headed by Arata, for example, would be a good candidate; they did build the apparatus and described highly reproducible experiments on accumulation of ^{4}He (2). I would consult many cold fusion researchers before selecting a team of proponents. Then I would select a highly qualified team of scientist who are highly critical of the reports published by proponents. I would call them opponents. Again, I would consult many cold fusion researchers before selecting a team of opponents. Proponents would be asked to perform experiments in presence of opponents. The claim would be validated if opponents were satisfied with conclusions of proponents. In case of a disagreement each team would be asked to write a report. Another group of experts would read the reports and decide the outcome.

4) What else is worth investigating? The number of claims is large and one must be selective. The most convincing nuclear signature in a CF setup, as far as I am concerned, were dramatic changes in isotopic ratios of trace elements accumulating in CF setups. It is conceivable that some of these elements result from redistribution of contamination but dramatic changes in isotopic ratios can not be explained in that way. To investigate the claim I would proceed, more or less, as described in 3 above.

5) For practical reasons I would limit the number of claims to investigate to three. The third claim would be the unexpected emission of nuclear particles, at very low rates, as reported by Jones (3). The rates of emission are too low to produce measurable heat. This, however, does not mean that the confirmation of the claim is not important. It might indicate that a nuclear process similar to hot fusion (emission of neutrons, protons, tritons and ^{3}He) can take place at ordinary temperatures. The name “cold fusion” would be appropriate for this kind of reaction, but not for other cold fusion processes.

6) What makes cold fusion possible at room temperatures? Is it screening by electrons or minima near the top of the

potential-energy-versus-distance curve? Such questions would be left for later studies. Another question to be left for further study has to do with our model of stellar energy generation. Is it conceivable that cold fusion also contributes to generation of heat inside stars. Is it conceivable that the sun emits fewer neutrinos than expected because not all of its heat is generated through fusion reactions with which we are familiar? Yes, I know that this is only a speculation. But who said that cold fusion is not possible at stellar temperatures?

7) I would totally ignore proposals dealing with practical applications at this time. Such proposals would evolve naturally if cold fusion were no longer blacklisted. The main overall task would be to decide about validity of scientific claims in the area of cold fusion. And about quality of research. Were methods of validation, in the area of CF, different from those used in other areas of science or not? Were major CF researchers qualified in their sub-disciplines? Was there any evidence of fraud or mutual deception?

8) Only highly respected scientists, preferably Nobel prize winners, would be selected to evaluate reports, and to announce decisions, which either confirm or refute claims made by cold fusion researchers. Time limit to reach decisions, and material support to conduct experiments, would be generous. Recall that the 1989 ERAB report was published only nine months after the discovery of cold fusion was announced. In my opinion this was not appropriate.

140) Seven papers from Kasagi

Ludwik Kowalski (5/1/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

This morning I received an e-mail message from Kasagi in Japan. He wrote: "Recently, I have found your www site on cold fusion by chance. And I knew, in the essay, that our works on low energy nuclear reaction have been cited several times. I appreciate it very much. I noticed that some of our papers are not in your hands; for example, that gives a detailed description of the experiment, spectra of observed particles, and so on. Thus, I decided to send them. Please find attached files (pdf files), which are our published papers on LENR in refereed journals." I am pleased that a scientist like Kasagi read my entries on this site. What follows are my short summaries based on fast reading of these seven paper. Dr. Kasagi saw the draft of this unit and made several small corrections.

At the same time (5/4/04) he wrote: "I started this kind of research in 1989, of course, after the big announcement [of the discovery of cold fusion]. Since I thought that low-energy nuclear reactions in materials were not investigated, I decided to measure DD reaction rates in metals by lowering incident energies as low as possible. The paper #2 is based on the work in 1989-1990 by using an ion source at Tokyo Institute of Technology where I was working at that time. I also started to observe reaction products during and after deuteron bombarding on metals. The paper #1 is based on the work in 1990-1994 by using a small Cockcroft-Walton machine in Tohoku University, where my friend was working for the Cyclotron laboratory, and, later on, I moved to the Laboratory of Nuclear Science (we have electron machines here). Thus, what led me to the cold fusion field was the original works of Fleishmann-Pons and Jones, although the first publicatio on this subject in the refereed journal was delayed too much."

Paper #1 (1995)
(1) J. Kasagi, T. Ohtsuki, K. Ishii and M. Hiraga, Energetic Protons and alpha-particles Emitted in 150-keV Deuteron Bombardment on Deuterated Ti, J. Phys. Soc. Jpn, 64, 777-783 (1995)

Deutrons of 150 keV were used to bombard a thick target of Ti loaded with D. In addition to expected 2.45 protons from the D(d,p)T reaction they discovered unexpected protons of 17 MeV and alpha particles of 6.5 MeV. The Ti, before loading it with D, was 99.5% pure and chemical composition of the remaining 0.5% (mostly O and Fe) was shown in the table. These people know that extraordinary claims call for extraordinary evidence and they investigated many kinds of scenarios, such as reactions in impurities, reactions due to neutrons, protons and ^{3}He. Here is one example. The dominant D(d,^{3}He)n reaction produces neutrons and ^{3}He. Thus targets were exposed to deliberately stronger doses of ^{3}He and n in order to show that not enough alpha particles were produced. Some protons could be explained as due to the D(^{3}He,p)^{4}He reactions (whose Q value is 18.35 MeV) but most high energy protons must be due to something else, claim the authors. Similar discussion was presented to rule out a possibility that most of the 6.5 MeV alpha particles are due to known reactions.

I was pleased to read this paper because I am familiar with instruments described by authors. They are similar to instruments I used in postdoctoral work at Columbia University about 35 years ago. It is interesting that the word "cold fusion" is not mentioned. Was it because the topic was considered pseudoscientific in Japan (as described in Mizuno's book) or because this work led the authors to cold fusion? In order to interpret the results they speculate that (for unknown reason) deuterons in Ti are sometimes much closer to each other than distances between Ti atoms. That would allow the D+D+D --> p+n+ a reaction in which the available energy of 21.62 MeV is shared among three products. The authors conclude: "However, this possibility requires an anomalously large enhancement factor which is not understood at present."
P.S.

The term LENR (low energy nuclear reactions) certainly appropriate for this study. But the term CF (cold fusion) is not appropriate because, by my definition in unit # 136, "Cold fusion is any process in which a nuclear reaction is produced without relying on traditional means, such as particle accelerators, neutron sources, stellar temperature temperatures, cosmic rays or alpha particles." Yes, formation of compound nuclei can be called fusion (of two nuclear drops) but even 150 keV is not "cold."

Paper #2 (1995)
J. Kasagi, T. Murakami, T. Yajima, S. Kobayashi and M. Ogawa, Measurements of the D+D Reaction in Ti Metal with Incident Energies between 4.7 and 18 keV, J. Phys. Soc. Jpn. 64, 3716-3722 (1995)

This paper is also devoted to D+D reactions in Ti but the energies of projectiles are lowered to 18 and 4.7 keV . Reaction cross sections, in that energy region, are very small, due to the Coulomb barrier. But they are known to be larger than expected. This effect has been attributed to screening (lowering of Coulomb barriers caused by orbital electrons. That is why the distance hydrogen nuclei in Ti and Pd are much shorter than H_2 molecules. Studying of screening effects was the motivation behind this investigations. Is this a camouflage for the "forbidden word" - cold fusion? The lowering of the Coulomb barrier is expressed in terms of so-called astronomical factor, S, (obtained by dividing a measured reaction cross section by the Gamow factor and by the incident energy). The main conclusion of this work is that screening in Ti is not significantly different from screening in a gas target (reported by other researchers).

Paper #3 (1997)
H. Yuki, T. Sato, T. Ohtsuki, T. Yorita, Y. Aoki, H. Yamazaki, J. Kasagi and K. Ishii, Measurement of the D(d,p)T reaction in Ti for 2.5 < Ed < 6.5 keV and electron screening in metal, J. Phys. Soc. Jpn. 66, 73-78 (1997)

This paper is also devoted to the study of D(d,p)T reaction in Ti but beam energies were between 2.5 and 6.5 keV. This was possible because the new accelerator was able to produce beams up to several hundreds microapmers (instead of only 2 in the previously used machine). Slight enhancement of cross sections (over those in bare D+D reaction) was noted. It was interpreted as caused by the electron screening. The first reference is for the "effect of the electronic environment on nuclear phenomena." It is G.T. Emery in Annu.Rev. Nucl. Sci. 22 (1972) 165.

The second reference is the 1989 CF paper of Fleischmann and Pons. The authors gave a very good description of controversies in that field; they wrote: "The so-called cold fusion has roused attention more generally on the influence of the environment where nuclear processes take place. Although most of the experiments reported at that time were known to have a difficulty in the reproducibility and, hence, to be under suspicion, the influence of the environment in various nuclear processes is one of the interesting subjects which need more study, because of its interdisciplinary nature involving nuclear physics, condensed matter physics, material science, and so on. In addition, one can develop its applications in various fields if the electron environment really affects the nuclear processes very strongly."

The paper focusses on difficulties of obtaining reliable data on cross sections in the region of very low energies. Overcoming some of these difficulties the authors demonstrate the enhancements of cross sections below 4 keV. The value of the screening potential for the D+D in Ti is reported as 19 eV, plus or minus 12 eV.

Paper #4 (1997)
H. Yuki, T. Sato, T. Ohtsuki, T. Yorita, Y. Aoki, H. Yamazaki and J. Kasagi, The D+D reactions in metal at bombarding energies below 5 keV, J. Phys. G: Nucl. Part. Phys. 23, 1459-1464 (1997).
This paper, published in an journal is devoted to the same topic as the previous paper. It shows that enhancements of D+D reactions in Yb are stronger that in Ti. The screening potential in palladium is reported as 81 eV, plus or minus 10 eV.

Paper #5 (1998)
H. Yuki, J. Kasagi, A.G. Lipson, T. Ohtsuki, T. Baba, T. Noda, B.F. Lyakhov and N. Asami, Anomalous enhancement of DD reactions in Pd and Au/Pd/PdO heterostructure targets under a low energy deuteron bombardment, JETP Letters 68 (1998) 823-829.

This paper is devoted to the same topic as the previous two papers but the metal is Pd (palladium). The enhancements in Pd (250 eV, plus or minus 15 eV.) was found to be much stronger than in Ti and Yb. Even more pronounced enhancements (601 eV) is reported for Au/Pd/PdO heterostructure. The authors believe that conductive electrons (due to mobility of D ions in Pd) might contribute to very large enhancements in Pd and in Au/Pd/PdO sandwich.

Paper #6 (2002)
J. Kasagi, H. Yuki, T. Baba, T. Noda, T. Ohtsuki and A.G. Lipson, Strongly enhanced DD fusion reaction in metals observed for keV D+ bombardment, J. Phys. Soc. Jpn, 71 (2002) 2881-2885.
This paper elaborates on results obtained in the previous one and provides additional data on enhancements in PdO. The authors begin by showing how the maximum possible deuterium density depends on temperature in several metals. In Ti, for example, the density is about $4*10^{22}$ atoms per cubic centimeter while in Au it is about two times less. In Pd, on the other hand, the density is about ten times smaller that in gold. In all cases the saturation density decreases with the temperature, as illustrated in Figure 1. Great effort was made to keep the deuteron densities stable during bombardments with highly intensive deuterium beams. The discussion focusses on the observed correlation between the deuterium densities (smaller in Pd) and screening potentials (largeer in Pd). The authors speculate that low density may indicate increased “fluidity” which in turn leads to a screening caused “not only by electrons but also by positive ions.”

Paper #7(2004)
J. Kasagi, Y. Yuki, T. Baba, A. Taguchi, M. Shimokawa and W. Galster, Strongly enhanced Li + D reaction in Pd observed for deuteron bombardment on PdLix with energies between 30 and 75 keV, J. Phys. Soc. Jpn. 73 (2004) 608-612.
This very recent paper paper also indictaes that “the enhancement in the Pd case cannot be explained by electron screening alone.” The conclusion is reached by analyzing the energy dependence of cross sections for Li(d, a) reactions occurring in host metals (Pd and Au). Beam energies were between 30 and 75 keV. Screening in PdLi (~1500 eV) was found to be much stronger than in AuLi (~60 eV). As in the previous paper, the authors speculate that high fluidity of Li ions in the Pd host might be responsible for the strong enhancement.

141) A paper from Dubna in Russia

Ludwik Kowalski (5/7/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

About a month ago I sent an e-mail message to a large number of cold fusion researchers in Europe. It was about the pending reevaluation of cold fusion by the DEO. F.A. Gareev read my message. On April 28, 2004 he wrote to me: "Dear Professor Ludwik Kowalski, Thank you very much for extremely important information about cold fusion. I was involved in this field starting from 1989 when information we get in NBI in Copenhagen where I spend some few years. I now nearly finished **review about cold transmutation in Russia** in russian and some my mechanisms cold transmutation. If you are able to read in russian I will be happy send for you my review paper and 2 original one. So give me your usual mail address. Professor of Physics, Gareev Fangil A."

The copy of the paper, published in 2003 (in "Geoinformatica, #1, p 51), arrived this morning. What follows is my translation of the first two and of the last sections. I do not want to translate the main section of the article because I am not familiar with that field of theoretical physics. The e-mail of the first author is gareev@thsun1.jinr.ru

P.S.
On May 11, 2004, he sent me a much longer paper (also in Russian) entitled "**Influence of excitation and ionization of the atoms on the velocity of nuclear processes at low energies.**" This 47-pages-long paper contains 246 references. The authors are: F.A. Gareev, I.E. Zhidkova and Yu.L. Ratis. In the summary they write: " We have concluded that cold transmutation of nuclei is possible in the framework of the modern physical theory excitation and ionization of atoms and universal resonance synchro-nization principle are responsible for it. Investigation of this phenomenon requires knowledge of different branches of science: nuclear and atomic physics, chemistry and electrochemistry, condensed matter and solid state physics,... The results of this research field can provide a new source of energy, substances and technologies."

Mechanism of cold transmutation of chemical elements

F.A. Gareev, G.F. Gareev, I E. Zhidkova
Joint Institute of Nuclear Research, Dubna, Russia

1. Introduction

Several publications describing low energy transmutations of atomic nuclei appeared recently. Such transmutations have been observed in electric explosions of thin metallic foils in liquids (1), in water solutions of salts exposed to ultrasound (2), in melting of zirconium (in a vacuum) by bombarding it with electrons (3), and in lead traversed by high electric current in a strong magnetic field (4). Neutrons were observed during electroacustical cavitation (5). It is significant to emphasize that cold transmutations of atomic nuclei consist an exothermic reactions in which the released energies

(MeVs) exceed the interaction energies (eVs and keVs) by 4 to 6 orders of magnitude. No gamma rays or alpha particles are emitted in these reactions. Theoretical objection against cold transmutations of atomic nuclei are based on “missing protons,” on low penetrability of Coulomb barriers, and on the absence of nuclear particles. The purpose of this work is to show how the unexpected nuclear processes can be explained in terms of resonance synchronization and resonant tunneling.

2. Mechanism of cold transmutations

Transmutation reactions must be isothermic because external influences causing them are weak. The energy must be conserved; the released energies are due to mass differences between the input and output channels. The “missing protons” objection can be removed by assuming that changes in Z are due to weak interactions:

$$A(Z,N) + n*e^- \rightarrow Z(Z-n,N) + nn_e,$$

and

$$A(Z,N) \rightarrow Z(Z+n,N) + ne- + nn_e,$$

where n is the number of leptons. Note that ‘ and “ refer neutrinos and antineutrinos, respectively. Probabilities of such interactions are extremely low and an amplifying mechanism must exist to make them observable. Such mechanism exists: it is the universal principle of resonant synchronization (7,8,9,10) and of resonant tunneling (11).

3. Principle of resonant synchronization

4. Conclusions

To summarize let us say that resonance synchronization and resonance tunneling amplify weak, acoustical and electromagnetic processes to such extent that cold transmutations of atomic nuclei become possible, at least in principle. Resonant amplification of the rate of transmutation depends only on the frequency of external interactions, it does not depend on the nature of these interactions. In recent experiments

In recent experiments large clusters of 100 to 1,000,000 atoms were observed to interact with laser beam pulses of very short duration. Energies of ions emitted from such clusters were shown to increase with sizes of clusters. In some cases atomic nuclei emitted ions whose energies approaching 1 MeV; such energies are sufficiently large to produce fusion. According to (18), for example, the $D(D,n)^3He$ reaction does take place when deuterium clusters interact with ultraist laser pulses. The authors concluded that the cross section of that fusion reaction increases rapidly with the size of the cluster.

The mechanism of cold transmutations consists of resonant amplification of reaction rates resulting from synchronized external interactions and from formation of large nuclear clusters. This can easily be verified by performing relatively simple and inexpensive experiments. The way is open for production of new chemical elements, and for generation of energy from radioactive waste. It turns out that different kinds of external interactions lead to similar results, as far as cold transmutations are concerned.

142) In memory of Eugene Mallove

Ludwik Kowalski (5/15/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Eugene Mallove, the author of “Fire from Ice,” is dead. He was killed yesterday. It was “a homicide and an investigation is underway," according to Steven B. Krivit. Steven is another young journalist trying to promote the reevaluation of cold fusion; his e-mail message made me aware of Eugene’s death this morning. It was a real shock. I met Eugene at the 10th International Conference on Cold Fusion. We had several conversations. We disagreed on some topics but I was very impressed by his personality. We lost an admirable fighter and a master of carefully chosen words. He died without knowing the outcome of the pending DOE reevaluation of cold fusion. It was Eugene who made me aware, two months ago, that the reevaluation project was informally announced.

Here are nice words that Steven Krivit wrote about Eugene. **”Gene is survived by his wife Joanne, his son, Ethan, and his daughter, Kim..... We believe that Gene Mallove will one day be recognized as one of the greatest science journalists of his time. He was an authoritative historian and innovative investigator within the new energy field. Through his 1991 book, "Fire from Ice: Searching for the Truth behind the Cold Fusion Furor," Gene was the first to courageously and boldly express the reality of cold fusion, long before any other science journalist dared to ask questions that challenged the prevailing view. In 1996, he reached an even broader audience with his highly educational video, ‘Cold Fusion: Fire From Water.’**

For 15 years, he worked tirelessly and relentlessly, at great personal sacrifice, to foster and oversee the development of cold fusion and other new energy experimentation at his New Energy Research Laboratory. He published Infinite Energy: The Magazine of New Energy Technology, which provided a "torch" of information that drew and enlightened many to the existence and legitimacy of cold fusion and other emerging new energy technologies. Most recently, he established the New Energy Foundation, a non-profit corporation, which provides grants to researchers and developers in the field of new energy.

Gene will be remembered for the immense support and encouragement he provided to cold fusion researchers around the world, whose progress and achievements he recognized, chronicled and publicized through a wide variety of media. His tremendous efforts have shown increasing success over the past few years and continue to bear fruit, as is evidenced by the growing media attention in support of cold fusion. Gene's generosity toward the scientific community, his commitment to the integrity of Science, and his dedication to creating a better world, will be forever appreciated and celebrated.”

Let me add that Mallove’s book is availble at <http://www.amazon.com>;I strongly recommend it for school libraries. Here is fragment from one of the reviewers of this fascinating book. “**In Fire from Ice,**

astronautical engineer and well-known author, Eugene Mallove, sheds a new and very different light on the cold fusion confusion. Based on personal interviews with many of the people involved, as well as his firsthand experiences in laboratories and scientific conferences, he offers a unique insiders view of that divisive controversy, while at the same time clearly explaining the relevant science and technology. And Dr. Mallove convincingly argues that cold fusion may yet prove to be real. A story of scientific ambition and professional rivalry, political intrigue and hard science, Fire from Ice is the fascinating account of one of the most intense and momentous scientific controversies of all time.

And another book reviewer wrote: "**"Mallove brings dramatically to life the human side of this important scientific controversy, which has tapped the emotions of its scientific participants in a way usually typical of major scientific revolutions. Fire from Ice is highly recommended reading for anyone who is interested in the nature of scientific controversy and scientific change. I frankly could not put the book down once I started it."**

In an Internet testimony his friend, Mark Plotkin writes: "**His greatest accomplishment and legacy will be the 52 bi-monthly magazine issues of Infinite Energy that he founded and edited. Infinite Energy magazine is a compendium of scientific research into all branches of unconventional energy research from contributors around the world. Many of the authors simply couldn't get published elsewhere, but had the courage and foresight to get most papers peer-reviewed before they were published. His magazine has thousands of loyal subscribers from over 40 countries including Russia and China. See www.infinite-energy.com.**

Gene traveled to dozens of international conferences, most of the time at great personal sacrifice simply to network with energy researchers and benefactors from around the world. He knew nearly everyone in the unconventional energy community worldwide. Gene has been a champion of cold fusion for many years highlighted by his organizing last summer's successful (International Conference on Cold Fusion) ICCF-10 held in Cambridge, Massachusetts from 24- 29 August 2003. Gene's presence has been the rare voice of scientific reason in a field filled with many phony claims and charlatans. See the web page with the experiments at http://www.lenr-canr.org/Experiments.htm.

Equally significant but perhaps not as well known is the *New Energy Foundation*, which he founded with the help of a generous wealthy anonymous benefactor. The New Energy Foundation has become a science-based clearinghouse for generating much needed funds for promising energy research leading to commercialization.

His latest triumph was to reverse over a decade of ignorance at Department of Energy by presenting compelling evidence of anomalous reactions of Low Energy Nuclear Reactions. DOE's decision to review the files on LENR aka Cold Fusion could possibly open a new area of scientific inquiry that has been closed since 1989. This was a triumph not just for Gene personally, but for every scientist who spoke as lone voices in large auditoriums. Gene's voice gave courage to those brave individuals who toiled in their laboratories, struggling to survive with virtually no funding, yet many developed innovative ways produce low energy nuclear reactions (LENR). Researchers often put their careers in jeopardy and only approached this field when retirement was assured.

Gene tirelessly climbed every mountain with courage and grace articulating truth in a field meriting

serious scientific investigation of anomalous energy phenomena despite constant criticism from ignorant skeptics who refused to examine even the best peer-reviewed data. One of the best examples of his fearless battles was when he reviewed Professor Bob Park's book “Voodoo Science.“ This bloody battle was over paradigm shifts in science revealing the complete ignorance of Bob Park by his refusal to consider any peer-reviewed data.

Gene's vision was of a world with abundant energy produced without fossil fuel or nuclear waste. It is now up to us to fearlessly make that vision a reality.

143) Social Aspects: Two Items

Ludwik Kowalski (5/21/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Item 1.
In browsing the Internet I found this page:

http://www.wpi.edu/Academics/Depts/Chemistry/Courses/CH215X/coldfusion.html

It is an old document, entitled "The Cornell Cold Fusion Archive" written by Bruce V. Lewenstein. The date is not specified; I think it was posted in 1994. The author asks questions belonging to the realm of "science and society". I think that these questions are worth thinking about. What follows are very extracts from his paper.

Introduction
". .....Many analysts have attempted to draw morals from cold fusion, labeling it "pathological" or worse, while others have pointed to the ongoing investigations and challenged critics to approach cold fusion with the openness that is claimed to be the hallmark of scientific inquiry. But we should look at the cold fusion saga neither as an episode of error nor as an exemplar in science. Instead we learn much more by considering what it tells us about science at the end of the twentieth century. Among the key issues:

a) What role does the press play in modern science?
b) Does the press merely disseminate the results of experimental investigations, or does it become an active player in the scientific process?
c) Was its behavior in the cold fusion saga somehow different than in other scientific episodes?
d) What changes in science communication does cold fusion foretell?
e) What is the place of politics in science? Are politicians just players on the outskirts of scientific investigation--or are they integral to modern scientific work?
f) What does politics in science accomplish?
g) How important is competition between research teams?
h) Is science fundamentally a search after nature's truths, or is it a game with winners and losers?
i) How do patents affect research?
j) How can a field that puts so much emphasis on priority of discovery deal with instances of double discoveries?

k) How can scientific commitments to open communication be reconciled with intellectual property rights?
l) And, perhaps most fundamental, what does it mean for science when experiments are unclear? If modern science depends on the belief that an experiment can yield an answer, how can it deal with ambiguity and incoherence in the research process?

Some scientists hope that cold fusion is unique. But I believe that the opposite is true. Virtually nothing about cold

fusion is new or different. Instead, the cold fusion saga simply illustrates much of what we already know about science--about how researchers interact with the media, with politicians, with the patent system, with each other, and with nature. We can use the history of cold fusion as a window through which to view modern science.

The History of Cold Fusion

. . . . Recollections differ on the outcome of the March 6 meeting. Jones believes the two groups agreed to simultaneously submit manuscripts to *Nature* , with no public statements before the submission on March 24. Pons and Fleischmann have said that they planned on the simultaneous submission, but made no commitment to staying quiet.

In the event, they didn't. A week after the meeting, they submitted a "preliminary note" on their work to a specialty journal that promised them quick publication. And the day before they were to meet Jones at the airport Federal Express office for the simultaneous submission, they announced their findings by press conference. Fleischmann showed up at the airport as scheduled, but Jones didn't; by then, furious at what he believed to be a broken agreement, he had faxed his manuscript to *Nature*

According to Frank Close, a British theoretical physicist whose book on cold fusion, *Too Hot to Handle* , is critical of Pons and Fleischmann, this prehistory explains much of the chaos that followed. Close argues that the competition between the groups fueled the secrecy and speed with which they worked, leading to incomplete experiments, misinterpretations that persisted because they were never disclosed and debated with other scientists, and various other mistakes. On the other hand, the succor which the groups provided to each other--after all, each of them seemed to offer independent verification of the same results--also explains the certainty with which each side proceeded to defend its findings.

. . . The findings of the two groups were not identical. Jones claimed--and in 1993 continues to believe--that his apparatus yields signs of a small amount of nuclear fusion, an amount so small that it comes nowhere close to 'break-even,' the point at which an experiment produces more energy than it consumes. Pons and Fleischmann, on the other hand, claim that their experiments produce more heat (and thus energy) than can be explained by the chemical reactions occurring in the cells. Pons and Fleischmann acknowledge that their experiments do not produce the typical signs of fusion--neutrons, gamma rays, tritium, and helium in amounts correlated with excess heat. They argue that a "hitherto unknown nuclear process"--a new form of fusion--must be causing the heat.

But whatever the findings of Pons, Fleischmann, and Jones, they were not the only actors in the cold fusion drama. Within days of the press conference, scientists around the world had taken up the challenge posed by the two teams, and attempted to replicate the experiment themselves . . . The first widely-publicized confirmation of heat production came on April 10 from Texas A&M University in College Station, Texas. On the same day, a team of researchers at the Georgia Institute of Technology in Atlanta announced that they had detected neutrons in a cold fusion cell, confirming that fusion was occurring. (The Georgia Tech team publicly withdrew its claims within a few days; with less fanfare, the Texas A&M group later did the same.) By the end of April, a dozen laboratories from around the world had publicly announced partial confirmations of some aspect of cold fusion; at least 40 articles had been submitted to refereed journals on cold fusion.

. . . The president of the University of Utah, who had already secured a $5 million commitment from his state legislature, asked for $25 million from the federal government. On May 1, at an American Physical Society meeting in Baltimore, physicists turned the tables on the chemists, producing a string of negative evaluations of cold fusion in a marathon session that began in the early evening and ran until well past midnight. A similar session took place the next evening, as well. The APS meeting marked the beginning of the end of media attention to cold fusion. But the scientific controversy rolled on. . . .

Understanding the Cold Fusion Saga

Cold fusion skeptics have called this sequence of events everything up through fraud, pointing to abundant evidence of sloppiness and error in many of the experiments. True believers prefer to highlight new experimental work and recall the admonition that all scientific knowledge is tentative and temporary. But both of these approaches are normative attempts to say what science ought to be. Instead, we should ask, What does cold fusion tell us about science as it really is ? What, after all, is unique about cold fusion?

It's not the presence of the press. The media have been covering science closely for most of this century, with the active support of the scientific community. In the United States, the American Chemical Society, the American Physical Society, and the American Association for the Advancement of Science are just three of the mainstream scientific organizations that devote significant fractions of their resources to cultivating press coverage of their fields. Press conferences have been used in the past, and will be used in the future, to present research both before and after it is published in the peer-reviewed literature.

A content analysis of the media coverage of cold fusion conducted by my students suggests it matched media coverage of other scientific topics. It met journalistic standards of "balance"-- that is, it reported both (or more) sides of the story. It rarely sensationalized. It was essentially accurate, erring primarily by the sin of omission. While scientists may not always be happy with the way science is covered by the media, many observers have come to understand that publication in the worlds of journalism and science have different meanings. Journalists will never provide the details scientists want, and scientists will rarely look for the "story" that excites journalists. Given the constraints under which science journalists operate, they did a competent job with cold fusion.

. . . One unusual aspect of cold fusion was the media's role as an active information broker. In several cases, reporters served as go-betweens for scientific groups that were not in direct contact.....Science communication is a complex, multifaceted, multidirectional process that involves many actors in various reciprocal arrangements. The media comprise merely one set of actors in the process. One new aspect of science communication in the cold fusion saga was the role of electronic communication (faxes, electronic mail, and computer bulletin boards) in the ongoing distribution of information about cold fusion. When preprints of manuscripts by the BYU and University of Utah teams became available about a week after the public announcement, copies of the preprints were faxed and (after having been scanned into computer-readable format) e-mailed around the world.

. . . Another area in which cold fusion is sometimes considered unique: competition. But competition between research teams is not new. In 1991, *Science* magazine featured an article on the ways in which teams try to beat each other to press, to shave just a few days off the publication process, in order to win to themselves the kudos of their peers. The physicist Philip Morrison has recently suggested that science is like sports. One implication is that while some parents may try to shield their children by saying that "doing your best" is the goal, we all know that for many people in sports, winning isn't everything, it's the only thing. The same holds true for many scientists. They are in the game because they want to win.

. . . The implication of the experimenter's regress for modern science is multifaceted. If science is not the objective investigator of nature that its proponents often assert, then what is the basis of its claim to a privileged role in our daily affairs? If, on the other hand, we say that nature greatly constrains the possible judgments that a researcher (or a citizen) can make, even in the face of experimental uncertainties, how should we deal with arguments that push the limits of the uncertainties? Cold fusion is not unique in raising these questions; it simply puts them in bold relief.

Conclusion

. . . Cold fusion doesn't teach us anything that we don't already know about science. But perhaps the saga of cold fusion itself may be explained by the confluence in a single case of all the things we already know. And since the same confluence of media, patents, controversy, and politics shows up in other recent examples of high-profile science (high temperature superconductors are probably the best example), it seems likely cold fusion is merely a harbinger of confluences to come. In other words, cold fusion is a prototypical example of the contemporary social context of science.

Item 2.

In browsing the Internet I also found this page:

http://www.newenergytimes.com/Audio/2003NagelAug25-2003PPP.mp3

It is a sound file, a public lecture of David Nagel at the 10th International Conference on Cold Fusion. Some social issues are touched upon. I was in the audience and my voice can be heard. I tried to compare cold fusion with

Manhattan project. The number of scientists working on cold fusion, worldwide, is about the same as the number of those who worked on Manhattan project. And caliber of scientists were more or less the same. How come, I asked, that in fifteen years cold fusion researchers could not produce a single item to convince other scientists that a new phenomenon was discovered? David said that those who developed atomic weapons had unlimited governmental support while those who discovered cold fusion were declared to be pseudo scientists. One can note that the efforts of weapon scientists were highly organized while the efforts of cold fusion researchers were not coordinated by an army general. Each of these two factors (support and coordination) is important.

144) Catalytic Mechanisms

Ludwik Kowalski (5/30/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Fusion of two deuterons into one helium atom, in hot plasma, is a rare process (one out of million fusion events). It is an exothermic process; the released energy of 23.7 MeV appears in the form of gamma rays. In condensed matter, on the other hand, production of helium has often been reported as a dominant fusion event in which the released energy appears in the form of heat and not in the form of gamma rays. What is the mechanism of nuclear fusion of deuterons in condensed matter? According to R.H. Parmenter (1) cold fusion in metallic lattices can be a two-step process whose steps are:

$^{1}H + {}^{2}H \rightarrow {}^{3}He + 5.4$ MeV

and

$^{3}He + {}^{2}H \rightarrow {}^{4}He + {}^{1}H + 18.26$ MeV

Note that common protons, presumably dissolved in the metallic lattice, play the catalytic role; they are used in the first step and released in the second step. The author claims that that the probability of the Coulomb barrier penetration, for the first step of the above sequence, is six orders of magnitude higher (but still very small), than for the direct fusion mechanism ($^{3}H + {}^{2}H \rightarrow {}^{4}He$). The ^{3}He produced in the first step (of the above sequence) has sufficient energy to overcome the Coulomb repulsion hindering the second step.

A sequence of two nuclear reactions, producing two ^{4}He atoms (and 22.3 MeV of energy), is also discussed. In that reaction neutrons play the catalytic role; ^{6}Li is supposed to be introduced into the lattice from the LiOD or LiOH salt dissolved in the electrolyte. The envisioned two-step process is:

$^{6}Li + n \rightarrow {}^{3}H + {}^{4}He + 4.8$ MeV

and

$^{3}H + {}^{2}H \rightarrow {}^{4}He + n + 17.5$ MeV

The issue of the critical mass (in a real cell not all neutrons produced in step 2 would react with ^{6}Li), and the issue of the absence of gamma rays, are not addressed by the author.

145) Non-equilibrated solids

Ludwik Kowalski (5/30/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

A typical distance between the atoms of a metallic crystal is 0.1 nm (one angsrom). The same applies to ions of hydrogen dissolved in metals when saturation densities (about one ion of hydrogen per atom of a metal) are reached. At such distances the attractive nuclear forces are too large to overcome the repulsive electric forces. That has been the main theoretical argument against cold fusion since its experimental discovery has been announced 15 years ago. But cold fusion has been observed by many investigators. The only way to consolidate theoretical arguments with massive experimental data, according to D. Cravens and D. Letts, is to postulate that cold fusion takes place at locations in which local conditions are far from equilibrium.

What follows is the first section of their practically-oriented paper. The authors refer to excess heat but their observations are probably applicable to all LENR-CANR processes {"Low Energy Nuclear Reactions and Chemically Assisted Nuclear Reactions" is a new (very auckward) name for what is commonly known as "cold fusion."}

1 Background

1.1 Static Equilibrium Often Produces Sporadic Results

The study of nuclear events at low temperatures often has resulted in frustrating investigations. The field of cold fusion has often been marked with sporadic and non-reproducible work. Critics have often pointed to the sporadic nature of the heat generation in electrolytic systems as indication of poor experimental procedure. However, it now seems that the sporadic nature of the results is a characteristic of an electrolytic system, which is initially near equilibrium, and slowly loaded to a transition point which is best described by the mathematical term as a chaotic transition. For example: slowly loading palladium can be driven between beta and gamma states and cause internal fluxes of deuterium.

Electrolytic cells using bulk palladium often require loading times of 10 to 20 times longer than would be expected by diffusion times of deuterium within the metal before they be expected to produce excess heat.[1] This was likely the cause of failure of early researchers who rushed to replicate Fleischmann's and Pons' early work.[2] In the first few years after the announcement, it was easier for a researcher to rush to print and claim negative results than to patiently wait until the system was fully loaded and driven into internal transitions that drive the reactions. As a result, early work more often than not failed to see excess heat.

This work will illustrate methods that will help drive CF systems off equilibrium and trigger internal events that lead to production of excess heat. The viewpoint taken here is that a system must be allowed to depart from static equilibrium before the required reactions can take place.

1.2 Theoretical Limitations

Most simple theoretical models fail to predict that nuclear reactions within a deuterated metal lattice can take place at significant rates. Such models rely on reaction rates that are based on equilibrium placement of deuterium within a metal lattice or on wave functions based on such placements. In particle models, the global average of the deuterium density within the metal is on the order of an Angstrom or more even for extreme loading ratios of D/Pd. It is clear that deuterium at such remote nuclear separations would not be expected to lead to nuclear events.

The imposition of dynamic conditions can cause the local separations of deuterium to be significantly different from the value predicted by the global density alone. It also seems that dynamic conditions provide ways for coupling of energy to drive the reactions and impurities within the lattice can allow for spin exchanges required for spin selection rules. It is a surety that the energy required to drive any nuclear events and energy released from such events are much larger than any external energy available to the deuterium based on a per atom division of energy.[3] This means that any external energy driving the possible nuclear events must act in a coherent way to channel energy from a large region of many atoms to the active sites.[4,5,6] This coherent channeling must involve over 10^8 atoms and likely many more. The experimental conditions then must make use of non-equilibrium events acting on a system that has some group coherent nature. The methods described here are simple and practical methods that can be used to produce such dynamic conditions, which may lead to the desired nuclear events. The assumption here is that the reactive nuclear species must be driven to a dynamic active state before the desire events can produce excess energy within the system. . . .

146) Scientific or not scientific?

Ludwik Kowalski (6/2/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

The following extracts (about scientific methods and pseudosciences) were found in browsing the Internet. I think that they are worth sharing. Keep in mind, however, that any wikipedia article can be changed by any reader. Thus what I extracted today may no longer be there tomorrow.

FROM ***http://en.wikipedia.org/wiki/Scientific_method***

1) The ***scientific method*** is a sequence or collection of procedures that are considered characteristic of scientific investigation and the acquisition of new scientific knowledge based upon physical evidence. This method is believed to distinguish science from other intellectual traditions, such as painting, philosophy or theology.

2) In the twentieth century Karl Popper introduced the idea that a hypothesis must be falsifiable ; that is, it must be capable of being demonstrated wrong. ..... Today falsifiability is often cited as a main distinction between science and pseudoscience.

3) The essential elements of the scientific method are traditionally described as follows: (a) Observation, (b) Hypothesis/Prediction, (c) Experiment (d) Collect data, (e) Conclusion and (f) Repeat. This can be called the hypothetico-deductive method. These activities do not describe all that scientists do. [It is an idealized description, not all discoveries are made in this way.] Science is a social activity, and one scientist's theory or proposal cannot become accepted unless it has become known to others (usually via publication, ideally peer reviewed publication), criticised, and finally accepted by the scientific community.

4) A hypothesis is a suggested explanation of the observations. It needs to be consistent with the phenomenon or set of facts observed. Sometimes this is nothing more than a "guess," especially in the case of students. Scientists use whatever they can—their own creativity (currently not well understood), ideas from other fields, induction , or even systematic guessing, or any other methods available—to come up with possible explanations for the phenomenon under study. There are no definitive guidelines for the production of new hypotheses. The history of science is filled with stories of scientists claiming a "flash of inspiration", or a hunch, which then motivated them to look for evidence to support or refute their idea.

5) A specific prediction should arise (as a logical consequence of the hypothesis), that can be put to the test of an experiment, which should allow concrete measurements. If results contradictory to the predictions are found, the hypothesis under test is incorrect or incomplete, requiring either revision or abandonment. If results consistent with the hypothesis are found, the hypothesis might be correct, but is always subject to further tests. Deductive reasoning is the way in which predictions are developed with which to test a hypothesis.

6) Experiments, whether widely accepted or not, should be performed by many different scientists so as to guard against bias, error, misunderstanding, fraud, etc. Those that seem to call into question, or even force rejection of, an existing previously satisfactory theory should be especially carefully checked. Scientific journals use a process of peer review ,

in which scientists' papers describing experimental results and their conclusions are submitted to a panel of fellow scientists for evaluation.

Scientists are rightly suspicious of results that do not go through this process. For example, the cold fusion experiments of Fleischmann and Pons were never peer reviewed—they were announced directly to the press before any other scientists were able to evaluate their efforts or reproduce their results. Their results have not been reproduced elsewhere else in the decades since [is this true?]; the press announcement was regarded at the time, by most nuclear physicists, as very likely wrong. Peer review may well have turned up problems and led to a closer examination of the experimental evidence Fleischmann, Pons, et al. believed they had found. Paul Kammerer 's experiments on acquired physical traits in amphibians (described in Arthur Koestler 's The Midwife Toad) seem to have been deliberately faked, while the confusion in the 60s and 70s about ' polywater ' seems to have been the result of micro contamination. Much embarrassment and wasted effort might have been avoided by proper peer review in many such cases.

7) The primary constraints on science are: (a) Publication, i.e. Peer review and (b) Resources (mostly, funding). It has not always been like this: in the old days of the "gentleman scientist" funding (and to a lesser extent publication) were far weaker constraints. Both of these constraints indirectly bring in the idealised method - work that too obviously violates the constraints will be difficult to publish and difficult to get funded.

8) The study of the scientific method is distinct from the practice of science and is more a part of the philosophy, history and sociology of science than of science itself. Such studies have limited direct impact on day-to-day scientific practice.

9) Scientific Method is often touted as determining which disciplines are scientific and which are not. Those which follow the scientific method might be considered sciences; those that do not are not. That is, method might be used as the criterion for demarcation between science and non-science.

10) In his book The Structure of Scientific Revolutions Kuhn argues that the process of observation and evaluation take place within a paradigm. 'A paradigm is what the members of a community of scientists share, and, conversely, a scientific community consists of men who share a paradigm' (postscript, part 1). On this account, science can be done only as a part of a community, and is inherently a communal activity. For Kuhn the fundamental difference between science and other disciplines is in the way in which the communities function.

FROM **http://en.wikipedia.org/wiki/Pseudoscience**

1) A pseudoscience is any body of knowledge purporting to be either both factual and scientific, or of an even higher standard of knowledge , but which fails to comply with scientific method. Motivations for the advocacy or promotion of pseudoscience range from simple naivety about the nature of science or of the scientific method, to deliberate deception for financial or other benefit. Some people consider some or all forms of pseudoscience to be harmless entertainment. Others, . . .consider all forms of pseudoscience to be harmful, whether or not they result in immediate harm to their followers.

2) Pseudoscience is distinguishable from revelation ,theology or spirituality in that it claims to offer insight into the physical world by "scientific" means (i.e., most usually in accordance with the scientific method). Systems of thought that rely upon "divine" or "inspired" knowledge are not considered pseudoscience if they do not claim to be scientific or to overturn well established science.

3) Pseudoscience also differs from protoscience . The latter may be defined as speculation or hypothesis which has not yet been tested adequately by the scientific method, but which is otherwise consisent with existing science or which, where inconsistent, offers reasonable account of the inconsistency. Pseudoscience, in contrast, is characteristically wanting adequate tests or the possibility of them, occasionally untestable in principle, and its supporters are frequently strident in insisting that existing scientific results are wrong.

4) The boundaries between pseudoscience, protoscience, and "real" science are often unclear to non-specialist observers.

They can even be obscure to experts. Many people have tried to offer objective criteria for the term, with mixed success. Often the term is used simply as a pejorative to express the speaker's low opinion of a given field, regardless of any objective measures.

5) After more than a century of active dialogue, the question of what marks the boundary of science remains fundamentally unsettled. As a consequence the issue of what constitutes pseudoscience continues to be controversial. . . . Examples of fields of endeavor that many consider – to varying extents – pseudoscientific include Cold fusion ,Pseudoarchaeology ,Gene Ray 's Time Cube ,astrology and homeopathy.

6) There are also young fields of science that are sometimes frowned upon by scientists from established fields, primarily because they are speculative in nature. [For example]: (a) exobiology /astrobiology , (b) Search for Extraterrestrial Intelligence (SETI) and (c) Communication with Extraterrestrial Intelligence (CETI). These fields are not considered pseudoscientific or protoscientific by most scientists, though, and they are studied at many universities and specialized institutes.

147) EXTRACTS FROM A GOOD OLD PAPER

Ludwik Kowalski (6/8/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Four years ago **Edmund Storms** published a long review paper entitled "**A Critical Evaluation of the Pons-Fleischmann Effect**." It appeared in two parts (1); the paper is also available over the Internet (2). In the abstract of the paper the author wrote: "Many new studies are available to make an objective evaluation of the Pons-Fleischmann effect possible. The phenomenon is conventionally known as "cold fusion," or "chemically assisted nuclear reactions (CANR)" when the environment is emphasized, or "low-energy nuclear-reactions (LENR)" if emphasis is placed on the process. A wide range of observations involving anomalous production of energy as well as nuclear products have been published. While many of the claims are still open to interpretation, the general conclusion is that an important, novel phenomenon has been discovered which deserves renewed interest." Below are arbitrarily selected extracts from this paper. Many findings described at the 10th anniversary of the announced discovery of cold fusion have been confirmed in subsequent five years. That is what, I suppose, prompted the pending DOE evaluation of cold fusion. Storms was probably an important promoter of this initiative.

= = = = = = = = = = = = = = =

1) Ten years of work worldwide have produced over 2500 published papers[5], many peer reviewed, which have answered most of the objections leveled by critics. It is now possible to make a more objective evaluation of the phenomenon than was previously possible. Unfortunately, during this time the claims have been the subject of considerable distortion. The reader is asked to lay aside the emotional reaction "cold fusion" can generate and read the following arguments with an open mind. Some readers will be put off by the clear conflict between claimed behavior and well accepted theory of nuclear interaction presently in vogue. The author is well aware of this problem. Nevertheless, a large collection of anomalous behavior must be explained. The fact that this behavior cannot be explained by conventional theory should only serve to challenge theoreticians rather than be used as justification for rejection. .....The field which is conventionally called "Cold Fusion" has grown and now should be called "Chemically-Assisted Nuclear Reactions" or "Low-Energy Nuclear Reactions," depending on the emphasis one wishes to apply. The claims are supported by a wide range of anomalous behaviors involving nuclear reactions and energy production.

2) Numerous critics have observed that "extraordinary claims require extraordinary proof." This is a very high standard which has prematurely doomed many new ideas to the trash bin, some deserving and some not. We need to realize that potential errors can be found by clever critics in any study, no matter how well done. Hence, a perfect proof is almost impossible to obtain until considerable information has accumulated. Such an accumulation is very slow and difficult if an idea is completely rejected, as has been done in this case. Consequently, at the very least, I would hope that the skeptical reader would entertain the possibility that some part of the claims deserve further study, even though all important questions have not, as yet, been answered.

3) If the process does not involve conventional fusion, what is producing the anomalous energy? Critics attribute the extra energy to error in measurement or normal, overlooked chemical processes. This assertion will be addressed in the following section. Four questions must be answered when evaluating this experimental work: (a) Was the calorimetric technique used by Pons and Fleischmann sufficiently stable and accurate to see the claimed extra energy? (b) Can

prosaic sources of chemical energy be ruled out? (c) Have other people replicated the claims using sufficiently stable and accurate calorimeters? (d) Have reasons for success or failure been discovered?

4) Before answering the first question, a general comment about the calorimetric method is necessary. Critics have misunderstood the difference between relative and absolute calorimetry in their search for errors.[12] Although the absolute approach was used during early measurements in order to detect an immediate production of energy, this method was later found to be unnecessary, because production of energy was found to require a long wait. This delay allows a null condition to be defined, independent of absolute knowledge of power production. Any random variation in the signal is also revealed during this interval. In addition, repeated calibration during this delay can be used to demonstrate that the calorimeter is stable. Consequently, referencing the data to an initial zero value, as is done in most publications, is convenient but not necessary.

Instead, power production is claimed when the signal rises above a previously steady but arbitrary background value. Seeing a signal rise out of the noise is easy and does not depend in any way on knowing the actual amount of heat being produced in the cell. The magnitude of the resulting energy is then calculated using the *change* in cell conditions and the calibration constant. All absolute values of error in temperature, voltage, current, and other conditions cancel, provided the values for these quantities have remained constant. As a result, the observed presence of excess energy is more certain than is its absolute value. If an error is to be found, it must explain how a sudden change can occur in previously stable conditions and how this change can be missed by repeated calibrations and studies of inert materials, so-called control experiments. Nevertheless, some overlooked errors are important and will be discussed.

5) Electrolytic action decomposes heavy water to give D_2 and O_2, which carry away chemical energy upon leaving the cell. Should some fraction of these gases unexpectedly react to reform water within the cell, the actual amount of energy being generated in the calorimeter would be uncertain. Kreysa *et al*.[13] immediately raised this issue because P-F did not address the problem in their original paper. Later P-F [14] stated that the amount of recombination was determined by measuring the amount of water which disappeared from the cell as a function of time and applied current, and that the amount was insignificant.

6) Overlooked by these studies is another possible source of error. Knowledge of the amount of energy being produced in such a calorimeter requires the thermal conductivity of the wall be known and stable. Stirring changes the effective thermal conductivity of the wall because the amount of stagnate fluid next to the wall is changed. This factor is very sensitive to the amount of fluid convection next to the wall and shows no saturation as convection is increased.[25] This effect can be seen in Figure 3 which shows the relationship between effective thermal conductivity of the cell wall as a function of stirring rate. Even mechanically stirred devices will suffer an error if the stirring rate should change. Whether this effect is important depends on the frequency of calibration, the type of calibration used, and the constancy of bubble action. Therefore, the effect of this error on the various studies using the isoperibolic method is hard to judge. To the extent that it operates, one should see an apparent positive as well as negative anomalous energy. All reported data show only positive excursions.

7) Three studies have evaluated the basic design of the P-F calorimeter. The first was commissioned by General Electric Co. and reported by Wilson *et al.* [26]. The two most serious problems they note are the change in calibration constant produced by liquid level change, and potential loss of heavy water with the evolving gases, thereby producing a loss of overlooked energy. The authors acknowledged that P-F avoided the effect of these errors, as well as several others, by frequent calibration. Thus, changes in cell conditions could be quickly eliminated as being the cause of anomalous energy. Although the authors claimed to find some minor mistakes, the final conclusion of this analysis is that only the magnitude of the anomalous energy can be questioned by their analysis, not its existence. Because their attempts to duplicate the claimed energy production using various types of palladium, cell designs, electrolytes, and anode metals were unsuccessful, they were not optimistic about the reality of the claims.

8) Before going on to examine attempts at replication, it is worth first discussing the P-F measurements in detail because they were the focus of so much criticism. Figure 4 shows a drawing of the P-F cell. In this case, electrolytic action occurs in a cell which is surrounded by a vacuum jacket that is silvered except near the top. Thus, the thermal barrier is located at the top of the cell, including the lid. This assembly is placed in a constant-temperature water bath. Contained in the cell along with the anode (Pt) and cathode (Pd) are a glass-covered heater, a single glass covered thermistor, and a

reference electrode. P-F answered some of the criticisms in several papers[30; 31; 32] from which the following observations can be summarized: Currents between 25 mA and 804 mA were used with most measurements taken above 100 mA. Thus, most measurements were outside of the critical current range for internal recombination- . Furthermore, they state that the amount of recombination was measured by monitoring the amount of D_2O used. Recombination was found to be no greater than 1% of applied power. Mixing was found to be adequate to eliminate temperature gradients based on experimental observation as noted above. with the resulting temperature rise and decay noted. This type of calibration allowed pulsed as
well as sustained heat production to be evaluated.

9) The hard-to-accept claim for a nuclear source is based, in part, on the belief that observed energy production exceeds any known chemical source. Therefore, the potential chemical sources must be examined. Before discussing this subject in detail, the reader should realize that a typical cell contains very few chemical components, all of which are stable with respect to each other. A chemical reaction can only be initiated by applying an electric current, a process which uses energy. Only after the water has been split into deuterium and oxygen can chemical reactions occur. This process causes several chemical reactions, including an uptake of deuterium by the palladium and slow deposition of lithium and platinum on the cathode surface.

Each of these reactions involve very little energy. Strain energy accumulates in the palladium and small amounts of reaction products such as D_2O_2 can accumulate in the solution under proper conditions. These processes have the potential to store energy within the cell. Only release of stored energy can be used to explain the anomalous energy, which appears after many hours of electrolysis. The magnitude of such processes was addressed in several papers. Kainthla *et al.*[37] discussed eight possible sources, including recombination, which has been already discussed above. The other sources are the energetics of PdD formation, the energetics of PdLi formation, and energy accumulation as stress. Each of these was found to be much too small to account for even the smallest reported excess energy. Handel[13].

10) These [calorimetric setups] share the following features: [44]; (a) The cells are sealed and contain a recombiner. As a result, no gas leaves the cell. Therefore, uncertainty in the amount of recombination is not an issue. Successful action by the recombiner is monitored using different methods including the change in gas pressure. (b) The cells contain a heater which maintains a constant inner temperature. Power to this heater is adjusted to compensate for any change in power production within the cell produced by electrolysis or by anomalous processes. This heater is also used to determine whether the power measurement, based on the flow rate and temperature change of the cooling fluid, is accurate. A sensitivity of better than ±0.01 W (±0.1%) is claimed. (c) The electrolytic cell, its surrounding heater, and the cooling-fluid channels are all contained within a silvered, evacuated dewar in order to isolate them from the environment. (d) The whole assembly is immersed in a fluid bath which maintains a constant environment of 30±0.003°C. This bath is also the source of cooling fluid. Consequently, most studies are done at a constant temperature of 30°C. (e) A constant flow pump is used to circulate cooling fluid. Flow rate is checked periodically by weighing the fluid. Better than 98% of power produced within the cell is captured in this fluid. (f) All aspects of the measurement are under computer control, which provides continuous monitoring, and redundant RTDs are used for temperature measurement. (g) The deuterium content of the palladium cathode is determined by measuring its change in resistance. (h) Most studies involve a similar calorimeter containing an inert cathode as a reference. Both calorimeters are run electrically in series and measurements alternate between the two systems using the same voltage and current meters.

Flow calorimetry is relatively simple and suffers from fewer errors compared to the isoperibolic method used by other people, as well as by P-F. Only four physical measurements are required. The applied power is determined by measuring applied voltage and current at the isothermal boundary, and the released power is obtained by measuring the flow rate and the temperature change of the cooling fluid. Internal temperature gradients are not important, stirring is not an issue, and uncertain recombination is not a source of potential error. Only unexpected changes in the measuring systems can introduce error. McKubre *et al*. have demonstrated their instruments to be stable and accurate through years of use. On the other hand, an evaluation of this study can assume prosaic errors which might have been overlooked in spite of this experience, as several skeptics have attempted to do. Two possibilities will be examined. . . .

11) Figure 5 compares many studies, some of which show a clear relationship between applied current density and heat

production. In addition, an example obtained by McKubre *et al.* is shown in Figure 10. Similar studies by Storms [50] and by Hasegewa *et al.*[48] are shown in figures 9 and 11, respectively. Indeed, even P-F mentioned this behavior but their advice was largely ignored by those who suffered failure.

What prosaic process could cause the apparent excess energy to rise as applied current is increased? Increased current has three major effects. It increases the AC component being measured in the DC current and voltage, increases the number of bubbles, increases the amount of energy being dissipated by the cell, and increases the chemical activity of deuterium at the cathode surface. The effect of an error in the measured current and voltage has been discussed above. Increased bubble production will cause increased mixing. For those studies using an isoperibolic calorimeter, this can only have a minor effect as explained above. Flow-type calorimeters would not be affected at all. Increased production of heat could have an effect if the calibration constant were not constant, but changed as the electrolyte temperature changed. Failure to recognize this nonlinear behavior could produce an error at temperature or current extremes. The author has seen this behavior after the current was applied to an isoperibolic calorimeter for a long time. Apparently, the path for heat loss can change, thereby changing the behavior of the calibration constant. Figure 8. Effect of average bulk composition on production of excess power using palladium wire. However, the effect is small, causing less than a 0.5 W error. Repeated calibrations, as is done in many studies, would reveal the problem. This effect would not apply to a flow-type calorimeter such as used by McKubre *et al*. because such calorimeters are largely immune to where heat is being produced within the cell.

12) The effect occurs in only a small fraction of samples but more often in certain batches than in others. Only a few organizations have the funding to allow many samples to be investigated for heat production. SRI [51] studied 176 samples with 19 giving excess energy. However, many of these studies were for the purpose of learning how high loading could be obtained rather than Figure 11. Effect of applied current on excess power shown by Hasegewa *et al.*[48] seeking excess energy. The successful samples correlated to a high degree with the average composition and many came from the same batch. Takahashi [52] reports studying twenty plates, only three of which gave excess energy in the 3-5 watt level. Both Storms[53] and Kobayashi *et al.*[54] were able to replicate excess energy production using material from the same batch of palladium which produced excess power for Takahashi. Ota *et al.* [55] studied 79 samples over a nine year period and found fourteen to give less than 0.25 W, 5 to give power between 0.25 W and 0.50 W and only three to produce greater than 0.50 W. The rest showed no sign of excess energy. Storms studied fourteen plates and found only six that produced excess power in the 1.1-4.5 watt range. The effect correlated with the amount of cracking experienced by the samples and the average composition. Miles *et al.*[56] found that 20% of their samples gave excess energy with a high fraction coming from a few batches.[57] The results are listed in Table 2. Those samples containing boron or cesium produced
a high success rate, while other samples and alloys were frequently dead. It is important to note that all samples supplied to

Miles by P-F produced excess energy. In addition, a sample which was found to produce excess energy at China Lake (U.S.) also produced excess when it was studied at the NHE Laboratory in Japan.[58] Thus, once again, the effect could be duplicated when the same material was used. This effect is attributed to the variable nature of palladium metal, especially because certain batches give a very high success rate. However, the behavior can also be explained by assuming poor stability in the calorimeters used, thus the insistence by critics that blank, control cells be studied. Unfortunately, no one working in this field has had funds to support an extensive study of blank cells, although most workers have studied a few such samples. Such blanks normally use platinum in place of palladium and H_2O in place of D_2O. When blank cells were studied, no excess energy is reported.[59] Many skeptics discount this claim by not trusting the experimenters to objectively evaluate the results or they attribute the claimed excess power to chance variations in the measuring system.

13) The above requirements provide many avenues for failure. Success, first of all, requires palladium which is able to achieve a critical composition at the surface.[60] The average bulk composition is only important because it is required to support this high surface composition. Unfortunately, most palladium forms cracks when it loads with deuterium so that the deuterium escapes faster than it can be delivered.[50] Only a small fraction of available palladium does not show this behavior. Second, the heavy water must be free of normal water to prevent deuterium in palladium from being diluted by normal hydrogen.[61; 62] Because heavy water quickly picks up normal water from the air, it can easily become diluted and made inactive. Once potentially active palladium has been acquired[63], it must be handled

correctly.

This includes making sure the surface is free of finger prints and other contaminants as well as scratches. Annealing must be done in a very good vacuum to prevent formation of even a monolayer of surface impurity. The ease with which palladium can suffer surface contamination is one of the important problems which is frequently overlooked. Crystal size is also thought to be important, a property which is strongly influenced by annealing. Treatment with Aqua Regia is sometimes needed to remove unavoidable surface films. After these pretreatments, the material must be subjected to proper loading conditions. Applying only a small current for the first several days improves the chance of reaching a high composition. Only after the composition has been achieved at stable value should the current be increased into the critical range. Too fast loading or premature application of high current can produce cracking, followed by immediate loss of deuterium.[51; 64] Palladium is much more sensitive to how it is treated than most people realize. These requirements were not known by most early workers in the field, hence success was more a matter of luck than skill. Even now, many attempts to duplicate the claims do not apply these lessons. Unless this experience is applied, a failed effort cannot be claimed as a true duplication.

14) Clearly, anomalous energy is not a product of a conventional fusion reaction, nor does it show the behavior found during "hot fusion." Nevertheless, anomalous emissions have been detected on numerous occasions, including neutrons, X-rays, g-rays, charged particles, as well as radiation from radioactive products. While such radiation along with production of radioactive and nonradioactive products suggest anomalous nuclear activity, this paper will not attempt to assess these claims. Helium is another possible nuclear product which can be produced by several nuclear reactions besides fusion. This element was looked for and found by numerous investigators in several different environments including in the gas[56; 65; 66; 67; 68; 69; 70], dissolved in the materials[71; 72; 73; 74; 75; 76; 77], and emitted as charged particles[78; 79; 80]. Naturally, not all studies are definitive and some failed to find helium when it was sought. While these observations are suggestive, only two independent measurements have provided a quantitative relationship between anomalous power production and helium production rate.

Both studies used all-metal systems and measured helium in the flowing gas generated during continuous electrolysis. Two different calorimeter types were used and the helium was measured at two different laboratories. These two studies are compared in Figure 12. Three conclusions can be drawn from the figure. First, the two studies agree very well, given the difficulty of the measurement. Second, the He/sec-watt values are largely independent of observed anomalous power, as would be expected if the two quantities are functionally related. Third, the average values are within a factor of 2 of being consistent with an energy of 24 MeV/helium atom, the value expected when ^{4}He is occasionally produced by conventional fusion. . . .

Thus, anomalous helium was found only when anomalous heat was detected. Only one cell, which used a Pd-Ce alloy, showed heat but no helium. This result is strongly against chance alone. When the helium producing branch of the fusion reaction has been previously observed using conventional fusion, a 23 MeV gamma emission has been detected. This radiation results because fusion of two deuterons produces only one product nucleus. Gamma emission is required to conserve momentum. Because this gamma energy is not detected during claimed anomalous energy production, most critics dismiss the claimed helium as being an artifact. The other two branches more frequently observed during conventional fusion are apparently not the source of significant energy in this environment. This distortion of expectations also adds to the skepticism.

15) To be successful, a theory [explanation of cold fusion] must answer at least five basic questions to explain the P-F effect and several other questions if the entire range of published observation is to be explained. (a) What mechanism allows the Coulomb barrier to be overcome? This question is basic and will have to explain how nuclei as heavy as palladium can suffer a reaction with nuclei as heavy as oxygen, in addition to the proposed fusion between deuterium nuclei. (b) What mechanism distributes the released energy throughout the lattice rather than requiring it to be focused on a few individual particles? This mechanism must also explain why some nuclear energy is retained by the nuclear products when these products are produced very near a surface. Otherwise, charged particles having significant energy to leave the material would not be detected. (c). How is the proposed mechanism related to the physical environment? Most present theories assume the nuclear reactions occur in b-PdD having a composition near PdD1.0. The model must explain why anomalous reactions occasionally involve other materials and why the required conditions are so difficult

to achieve. (d) What nuclear reaction is the source of observed helium? Fusion is not the only conceivable source of helium as a nuclear product. (e) If helium results from a fusion reaction, what mechanism allows conservation of momentum and energy, and what mechanism distorts the reaction paths to produce helium rather than neutrons and tritium?

16) Calorimetry is a well understood technique which has been applied in various forms for over a hundred years. A vast literature of chemistry and physics is based on such measurements. While measurement of power at the microwatt level is a challenge, measurement of watts, as is being done here, is not considered difficult. Prof. Hansen has suggested that a calorimeter cannot be trusted unless it has demonstrated accuracy in measuring the heat from a known reaction. This is a fair request provided absolute calorimetry is used. However, as noted at the beginning of this review, relative measurements are actually being made. Stability is the only requirement, a condition which is much easier to evaluate and much less prone to hidden error. This is not to say that all claims for anomalous energy are correct or accurate. The question which must be examined is whether some studies are sufficiently correct and accurate to demonstrate the claims to be highly probable, not necessarily absolutely certain. When such evaluations are made, the critic needs to keep in mind the potential magnitude of suggested errors. Just because an error can be imagined and justified does not mean it can explain multiwatts of apparent power production. In general, the magnitude of the effect has frequently overwhelmed any plausible errors or prosaic explanations. The statement that the claims are not convincing is often heard. While this euphemism is actually a gentle way of saying, ”I just don’t believe you,” one needs to ask just what is not believed and just what deserves additional study. Is it rational to reject everything just because some part does not make sense? Would it not be better to support some focused work on the subject to answer a few basic questions? What are we to make of the consistent patterns of behavior as well as the influence of material properties and the presence of helium, a possible nuclear product? Is it reasonable to believe that numerous independent studies show the same patterns just because of chance? While such arguments are not a proof, they are commonly used by prudent people to evaluate all aspects of life. Indeed, this is the rationale behind requiring many duplications of a claim, a condition which has been met in this case. When a new phenomena is evaluated, a belief system based on probabilities needs to be adopted. An absolute rejection or acceptance is not useful. The issue is whether the likelihood of the phenomena being real is sufficiently large so as to justify further work. In the case of the CANR claims, I suggest further study is justified.

17) CONCLUSION: The claims for anomalous energy production using electrolysis of heavy water have been evaluated and found to have a high probability of being caused by a novel phenomenon. In addition, the most likely source of the heat is a nuclear reaction which produces helium. This nuclear reaction is not normal fusion and it does not follow the rules required by conventional theory. Numerous models have been proposed to explain the observations, but none at the present time can account for all of the reported behaviors. More work is required to determine which of the behaviors are part of this novel phenomenon and which can be explained by ordinary processes. However, the claims have now reached a level of understanding which justifies a reexamination of the published work and attention by the scientific community.

148) ON DIFFICULTIES COMMUNICATING

Ludwik Kowalski (6/9/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Introduction
Chemists and material scientists are often more familiar with physics, than physicists are with chemistry or material science. That is why reports written by chemists or material scientists are likely to be frustrating reading to a physics teacher, such as myself. This is unfortunate because cold fusion is a field involving three disciplines. This essay illustrates the kind of frustration I encounter. It is not a criticism of the paper that I am using as an example; that paper was written by an expert--Edmund Storms--and it was presented at a scientific conference attended by other experts. I suppose that most of them could find the answers to my questions "between the lines" of the reports (they are interested in what is new and not in what has already been debated). Experts communicating across the borders of scientific disciplines should be aware that their messages are not always clear to others.

How It Started
In browsing the Internet I found the following e-mail message (January 28, 2000), authored by E. Storms.

"I would like to invite the resident skeptics and curious to view the results of a successful cold fusion experiment, in particular a study of the Pons-Fleischmann Effect. ...... To give you a little background, I have been studying the P-F effect for about 10 years starting at the Los Alamos National Laboratory. During that time I have seen anomalous energy production from Pd-D_2O cells having values over a range up to 7.5 watts. Recently, I have constructed several flow-type calorimeters having much better sensitivity and stability than the isoperibolic type I was using. Consequently, I can detect and believe lower excess power levels, values I would have ignored before. Recently, several samples produced anomalous power and will be described in detail at ICCF-8. I hope this rare success will stir up some interest and suggestions. Please feel free to give it your best shot. "

Fortunately, Storms' ICCF-8 paper can be downloaded from the Internet. Google pointed to that paper after the following search phrase was specified:

E. Storms, 2000. "Excess Power Production from Platinum Cathodes Using the Pons-Fleischmann Effect," in *Eighth International Conference on Cold Fusion.* 2000 Lerici (La Spezia), Italy: Italian Physical Society, Bologna,Italy.

What follows is the text of that important paper. I am showing it to identify places at which I faced conceptual difficulties. My numbered questions are inserted in red capital letters. The figures, and the list of references, are skipped to shorten the description. I notice the term "Pons-Fleischmann effect' in the title of Storms' paper. Presumably this refers to generation of unexplained exess heat. That is not the same thing as as the term "cold fusion," invented long before 1989, and defined as a nuclear process taking place in condensed matter. The two are likely to be related but this should not prevent us from saying that the P-F effects belongs to chemistry while the CF effects belong to physics. Division of labor along traditional lines is useful.

EXCESS POWER PRODUCTION FROM PLATINUM CATHODES USING THE PONS-FLEISCHMANN EFFECT

Edmund Storms Energy K. Systems,
2140 Paseo Ponderosa, Santa Fe, NM 87501

ABSTRACT
Excess power was produced using a platinum cathode. Efforts to produce active cathodes by plating palladium onto various metals were largely unsucessful.

INTRODUCTION
Palladium has been the cathode of choice since Pons and Fleischmann made their original claims. Occasionally, anomalous energy has been claimed to result from other elements such as Pt[1; 2], Au[3], Ti[4]. Thin layers of palladium on various inert substrates have also been claimed to produce anomalous energy [5; 6; 7; 8]. From this collection of experience, one might conclude that any layer of Pd made to stick tightly to the surface of another material would produce energy with greater ease than the bulk metal. This assumption has been found to be false even though such material can achieve a D/Pd ratio greater than 1.5[9]. Layers of electroplated Pd can be just as difficult to reproduce as bulk material. Although several successful samples were made, this paper will describe only one example of uncoated platinum which produced excess energy after being electrolyzed for an extended time in LiOD+D_2O.

EXPERIMENTAL

Calorimeter Design:

The calorimeter, shown in Fig. 1, consists of a Pyrex glass cell surrounded by a watercooled jacket. This assembly is contained in a vacuum dewar, thereby allowing most of the energy lost through the lid to be picked up by the cooling water. A magnetic stirrer is used to stir the electrolyte, thereby reducing temperature gradients.

(1*) AT WHAT RATE WAS THE LIQUID HEATED BY THE STEERER?
(2*) WHY SHOULD I ASSUME THAT IT WAS A NEGLIGIBLE RATE IN COMPARISON WITH THE EXCESS POWER (EP~ 0.1 W)?

The entire assembly along with all reference resistors is contained in a constant temperature environment. Table I lists values and uncertainties for the various quantities. The electrolytic cell contains three linear thermistors within the electrolyte, one near the top of the solution, one near the bottom, and the third just above the cathode. The anode is equidistant (0.5 cm) from the flat plate cathode (1 cm x 2 cm). Temperature of distilled water flowing through the jacket is measured just as it enters the jacket and just as it leaves. Data are recorded every 15 min. using a National Instruments data acquisition system after averaging 15000 values. The flow rate is measured by allowing the water after it leaves the calorimeter to fill a container on a balance while the weight and time are recorded every 120 sec. In addition, the cell contains a Pt-coated-carbon recombiner catalyst

(3*) TO “RECOMBINE” MEANS TO MAKE H_2O FROM H_2 AND O_2 THAT ARE PRODUCED IN THE CELL. (AN EXOTHERMIC PROCESS).

and an exposed Pt wire heater for calibration. Luggin capillaries

(4*) WHAT ARE LUGGIN CAPILARIES?

allow the voltage between a platinum reference electrode and the cathode to be measured.

(5*) WHAT IS THE THIRD (REFERENCE) ELECTRODE FOR?
(6*) WHERE IS THE ELECTRIC DIAGRAM?
(7*) WHICH VOLTAGE WAS USED TO CALCULATE THE INPUT POWER?

Because the cell is connected to an oil reservoir, any gas generated within the cell can be detected by weighing the oil displaced onto a balance.

(8*) WHICH GASSES WERE GATHERED IN THE CELL AND AT WHAT RATES?
(9*) WAS ANY CHEMICAL ENERGY GENERATED IN PRODUCING THESE GASSES?

Samples can be quickly changed or replaced by an inert cathode for calibration.

(10*) SAMPLES OF WHAT?
(11*) WHY ARE SUCH CHANGES OR REPLACEMENTS NECESSARY?
(12*) WHAT ELSE CHANGES WHEN A SAMPLE IS REPLACED?

Lengthy studies of inert platinum show a stability of ±75 mW.

(13*) WHEN IS PLATINUM NOT INERT?

Calibration and Error

A typical calibration for the flow-mode is shown in Fig. 2, using a clean piece of platinum for the cathode.

(14*) WHAT IS FLOW MODE? WHAT ARE OTHER MODES?
(15*) TO CALIBRATE USUALLY MEANS TO ESTABLISH A RELATION BETWEE TWO OR MORE VARIABLES. WHAT VALUES ARE INVOLVED IN THIS CALIBRATION?

Values are taken both going up and going down in applied power in the same manner as the sweeps described later. The standard deviation of the electrolytic values from the least-squares line is ±30 mW

(16*) WHAT IS THE “ELECTROLYTIC VALUE” (EXPRESSED IN WATTS)?
(17*) “THE LEAST SQUARES LINE” OF WHAT VERSUS WHAT?

which is the same as the standard deviation from a constant value when stable excess energy is being observed at low applied power.

(18*) HOW WAS “STABLE EXCESS HEAT” DEFINED OPERATIONALLY?

Figure 1. Drawing of the calorimeter. The electrolyte is 65 ml of 0.3 N LiOD and the anode is Pt mesh. The cell lid is Lucite and the Dewar lid is expanded foam insulation. All thermistors are glass covered. Time to reach a steady temperature is 50 min.

TABLE I
Summary of uncertainties in measured quantities
Water temperature entering the jacket = 20±0.02°
Environment temperature = 20±0.03°
Flow rate = 31.00±0.05 g/min (long term variation)
Precision of current measurement = ±<0.001 A
Precision of voltage measurement = ±<0.001 V
Precision of temperature measurement = ±<0.005°
Absolute accuracy of temperature measurement = 0.1°
Stirring rate = 300 rpm ± 1 rpm
Average heat capture efficiency = 98±0.5%

(19*) WHICH VOLTAGES WERE MEASURED AND HOW WERE THEY USED?

This scatter increases to ±0.1 W at the upper limit of applied power (27 W). A zero drift as much as -0.05 W has been observed over an extended time. Consequently, changes in excess energy production are more accurate than absolute values. Good agreement between the electrolytic- and Joule-based calibrations shows that the location of heat production does not affect the accuracy of the device. Doubling the fluid flow from 22.3 g/min to 45.3 g/min caused a change in the calibration constant from 0.0732 W/degree-g/min to 0.0738 W/degree-g/min, indicating that good thermal mixing is achieved in the exiting cooling water.

(20*) WHAT WATTAGE IS USED IN THE UNIT OF CALIBRATION CONSTANT?
(21*) HOW WAS THE CALIBRATION CONSTANT DETERMINED?

Because samples can be easily changed, the cathode is frequently replaced by clean platinum when the need arises to recalibrate. Good stability is shown by a scatter of only ±1.6% in the calibration constant when measured many times over three months.

Figure 2. Comparison between electrolytic and heater calibrations before and after the study using the flow method. The heater and electrolysis agree within 1.2%.

(22*) I SUPPOSE THAT DJ (SEE FIGURE 1) IS THE TEMPERATURE DIFFERENCE BETWEEN WATER-OUT AND WATER-IN. BUT WHY IS IT DJ AND NOT DT?
(23*) IN FIGURE 2 T FOR THE TEMPERATURE "ACROSS THE JACKET."
IS IT THE SAME AS DJ?

The cell can also be used as a rough isoperibolic calorimeter by measuring the average temperature between the electrolyte and the cooling jacket.

(24*) OK, THIS BE THE SECOND MODE OF OPERATION. (FIRST WAS THE FLOW MODE).
(25*) FORTUNATELY, I KNOW WHAT "ISOPERIBOLIC" IS. BUT MANY PHYSICISTS
ARE LIKELY TO BE CONFUSED BY THIS ADJECTIVE.

However, this method is not stable, in spite of active stirring, because of changes in the convection currents in the electrolyte and in the jacket. Figure 3 shows how the average temperature across the jacket changed between the first and final calibration using the electrolytic method and clean Pt.

Figure 3. Comparison between applied electrolytic watts and the average temperature across the jacket for two calibration runs.

Excess Energy Measurement

Figures 4, 5, and 6 show the time history for excess power (EP) production using a special platinum cathode.

(26*) WHAT MAKES THIS ELECTRODE "SPECIAL"?

Current sweeps consist of stepping the current up in value, waiting for the calorimeter to achieve steady-state (50 min), taking five values, and repeating the process.

(27*) HOW WERE THE VALUES OF EXCESS POWER (EP) CALCULATED?
(28*) THE ERROR BARS ARE GIVEN IN TABLE 1. HOW SHOULD I USE THEM TO ESTIMATE ERROR BARS FOR THE VALUES OF EP?

After reaching 3 A, the current is reduced in steps. Notice in Fig. 4 that the expected EP was achieved at 0.5 A and 1.0 A, but decayed away when 1.5 A was applied.

(29*) WHAT IS THE “EXPECTED” EXCESS POWER?
(30*) IF IT MEANS “EXPECTED ON THE BASIS OF ANOTHER REPORT,” THEN WHAT REPORT? IF IT MEANS “THEORETICALLY EXPECTED,” THEN BY WHAT THEORY?

A sweep taken after the decay showed very little EP. After the current was turned off for a brief time, the study was resumed in Fig. 5. Notice that the EP again gradually increased after 0.5A was applied. Sweep #3 again showed EP and this continued while 0.75A and 1.0A were applied. However, application of 1.5A again caused the EP to decay away.

Figure 4. Time history of excess power production from a Pt sample.

Once again the current was turned off. Application of 0.5 A, shown in Fig. 6, again showed EP. The calorimeter was calibrated at 430 h using the internal heater and later using an inert Pt cathode. This experience shows a consistent pattern of behavior which was repeated once again, but is not shown here. The first sweep is shown as applied current vs EP in Fig. 7. Notice that excess power is indicated by the isoperibolic method during this initial sweep, but later sweeps do not show an effect because of a change in calibration, as indicated in Fig. 3. Also notice that the excess power falls on a higher line upon reduction in applied current. Subsequent cycles, as shown in Fig. 8, produce excess power that fall on this higher line. The final relationship is linear and extrapolates to zero EP at zero applied current, in contrast to the behavior of palladium, which requires a critical applied current before EP is produced. Figure 9 shows the sweeps taken later using different numbers of values to produce the plotted average and these are compared to the heater calibration.

Figure 5. Time history of excess power production from a Pt sample.

DISCUSSION

A large average composition within the cathode is thought required to produce excess energy. Yet many researchers have failed to produce excess power after achieving large compositions, for example Nakata et al.[10]. Now, metals that do not even dissolve hydrogen are found to make excess energy. Clearly, additional variables are operating.

Figure 6. Time history of excess power production from a Pt sample.

Figure 7. Comparison between excess energy measured using flow method and isoperipolic method during first current sweep.

In the case of platinum, this study suggests that an energy-active layer of unknown composition can deposit on a Pt surface. This observation might also be related to the frequent detection of Pt on the Pd cathode after excess energy is observed. Such a layer is slow to form, which is consistent with the observed long delay in producing excess energy, and, for this sample, it is unstable. Is it possible that such a layer might be the active material in all studies, even when palladium is used?. McKubre et al. [11] also suggest that a critical layer is required to maintain the required high composition in Pd. Perhaps this is the actual active material. If this is the case, the bulk properties of palladium are only important in that they must support a critical concentration within this layer. Since palladium can easily permit loss into the metal, such material might be the worst substrate to use. Platinum, gold, and other inert materials would appear to be better choices. Use of such materials would only require forming the active layer without a need to use special batches of the substrate. If this suggestion is true, significant changes in various theories will be required.

Figure 8. Applied current vs excess power for the various sweeps, compared to Pt calibrations taken before and after the study.

Figure 9. Applied current vs excess power for sweeps using different number of values to average are compared to the heater calibration.

****

P.S. (6/30/04)

Let me end with a quote from a paper E. Storms wrote for those who are not familiar with excess heat calorimetry:

"Calorimetry is the measurement of heat energy. Although this is an old science that underpins much of thermodynamics and modern chemistry, when such measure-ments are applied to LENR, several unique problems become immediately apparent. For the LENR effect to be initiated, normal energy is frequently required as electric power to produce higher temperature, to generate hydrogen ions, or to stimulate the process in various ways. Consequently, the small amount of anomalous energy being sought is fre-quently superimposed on a large heat flux resulting from normal processes. As a result, the calorimeter must be able to handle large heat flux while being sufficiently sensitive and stable to see the small amounts of anomalous energy. This requirement has severely limited calorimeter design and has complicated evaluation of results. However, as better calorimetry has been applied to the problem, sufficient anomalous power has been re-ported to completely overwhelm uncertainties in heat measurement. This situation con-tinues to improve as ways are found to generate increasing amounts of anomalous power."

149) A message from a young outsider

Ludwik Kowalski (6/24/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

This morning I received the following an e-mail message from David Pesta:

"I am finally starting to understand what this issue is all about after finding your site. To the lay person, all of the other technical material out there is incomprehensible. Keep up the great work! David."

My reply to this compliment was a simple "thank you." But a little later I sent another message. Here it is: "David: It occurred to me, after replying with one word, that I should ask you for a favor. Can you summarize, on one or more pages, your own experience with the issue of cold fusion? I would be glad to post your piece (anonymously, if you prefer) on my web site. Tell a little bit about yourself, at the beginning, and about your experience with the subject." Several hours later I received a short answer; it is indeed worth sharing. The piece shows how a young high school student learned about cold fusion in 1996. It also shows what he thinks about the field today, after graduating from a university. I hope that there are many open-minded young scientists with similar experience. Will the upcoming DOE investigation be positive enough to encourage some of them to become cold fusion researchers? I hope so. Most of the cold fusion researchers, as far as I know, are in their 60's or older. David wrote:

" Hello; you can post this piece. My experience with cold fusion may not be impressive, depending upon what sort of things you are looking for.

I graduated magna cum laude from Oklahoma State University in 2001 with a degree in biochemistry. I have an A.S. Degree in physics. In 1996 when I was a junior in high school, my chemistry teacher was on a mission to enlighten us on the pseudo-science that pervades society and how to steer clear of baloney. He had a lot of knowledge, but he never did have a good baloney detector kit and seemed to make appeals to emotion rather than reason. I suppose that was suspicion number one. As a part of his mini curriculum, he showed us a television program about cold fusion, I believe it was part of a series by Nova.

After I watched the presentation, I was left with a strong suspicion that there was more to this issue than the program was reporting. Two things went through my mind.

1. After all the negative media coverage, the two scientists (Fleischmann and Pons) admitted some mistakes but still sincerely believed that many of their initial results were genuine. These two scientists were distinguished and seasoned researchers who never exhibited any sort of history indicative of the kind of accusations that they were receiving. They would have known better than to make up fake evidence and hope that nobody would notice as society tried to implement the fake technology. What is the likelihood of formerly reliable scientists out of the blue trying to do something silly like that? That would be like guaranteeing destruction to their reputation and ending their long career as a scientist, and they would have done it deliberately together. No, something fishy is going on here.

2. Other scientists set out to reproduce the experiment in their own laboratories. Maybe the experiments were hard to reproduce precisely and the results were very sensitive to the way the original scientists conducted the experiments. That being a possible scenario, wouldn't it be sensible for the skeptical scientists to visit the laboratory of Fleischmann and Pons and confirm or deny their work directly? If I were a scientist in the field and I heard that someone stumbled across some positive results in their lab over an issue this momentous, I would be the first one on a flight to their location to see it for myself! The film didn't mention any visit of scientists to their laboratory. Considering how

important such a finding would be, it just didn't seem like there was much of an effort placed on reproducing their experiment exactly. To me, it seemed like people were too quick to give up. Cutting federal funds to future research in cold fusion soon after made this
point as well.

These weren't strong reasons to completely doubt the scientific community. But still, for some reason, I walked away from that video with the impression that the scientific community may be missing out on something important and that further investigation should be done before putting the matter to rest. The idea that cold fusion may still be possible remained a thought in the back of my mind ever since.

Last night, while working on a tricky html problem, I was struck with inspiration to see if the scientists of 2004 were making any progress on cold fusion, or if it was a dead field. To my surprise, your website made a lot of issues more clear. I literally read articles all night long and got no sleep, and I haven't done that since the days of college when I was forced to study all night. I am amazed that there is progress that confirms my suspicions that the two scientists Fleischmann and Pons may have actually stumbled onto something. I love rooting for the underdog, especially when there is momentum behind them. I look forward to seeing what actually ends up being discovered, if anything.

Skepticism is great, as long as it is reasonable and not based upon emotion. I do believe that conspiracies happen in American science. Most of them are accidental, but because we are human beings, they happen. And history shows it. Have a great day, David."

After reading my item #148 Richard Eskimos sent me a set of comments. He wrote:

"I noticed questions about Storms' paper on your website. Since I've been looking at the paper in detail, I may have some of the answers for you. In any case, it will help with my explanation of the Storms/Shanahan question [see item #151]. I've attached the .html file with my answers."

WHAT FOLLOWS IT THE CONTENT OF RICHRD'S FILE. THE ONLY DIFFERENCE BETWEEN ITEM #148 AND THIS ITEM #150 ARE RICHARD'S COMMENTS AND LINKS. THEY FOLLOW MY QUESTIONS PRINTED IN RED. LET ME ADD THAT RICHARD ESKIMOS IS THE AUTHOR OF ITEM #151

150) ON DIFFICULTIES COMMUNICATING

Ludwik Kowalski (6/9/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Introduction
Chemists and material scientists are often more familiar with physics, than physicists are with chemistry or material science. That is why reports written by chemists or material scientists are likely to be frustrating reading to a physics teacher, such as myself. This is unfortunate because cold fusion is a field involving three disciplines. This essay illustrates the kind of frustration I encounter. It is not a criticism of the paper that I am using as an example; that paper was written by an expert--Edmund Storms--and it was presented at a scientific conference attended by other experts. I suppose that most of them could find the answers to my questions “between the lines” of the reports (they are interested in what is new and not in what has already been debated). Experts communicating across the borders of scientific disciplines should be aware that their messages are not always clear to others.

How It Started
In browsing the Internet I found the following e-mail message (January 28, 2000), authored by E. Storms.

“I would like to invite the resident skeptics and curious to view the results of a successful cold fusion experiment, in particular a study of the Pons-Fleischmann Effect. ..... To give you a little background, I have been studying the P-F effect for about 10 years starting at the Los Alamos National Laboratory. During that time I have seen anomalous energy production from Pd-D_2O cells having values over a range up to 7.5 watts. Recently, I have constructed several flow-type calorimeters having much better sensitivity and stability than the isoperibolic type I was using. Consequently, I can detect and believe lower excess power levels, values I would have ignored before. Recently, several samples produced anomalous power and will be described in detail at ICCF-8. I hope this rare success will stir up some interest and suggestions. Please feel free to give it your best shot. “

Fortunately, Storms’ ICCF-8 paper can be downloaded from the Internet. Google pointed to that paper after the following search phrase was specified:

E. Storms, 2000. "Excess Power Production from Platinum Cathodes Using the Pons-Fleischmann Effect," in *Eighth International Conference on Cold Fusion.* 2000 Lerici (La Spezia), Italy: Italian Physical Society, Bologna,Italy.

What follows is the text of that important paper. I am showing it to identify places at which I faced conceptual difficulties. My numbered questions are inserted in red capital letters. The figures, and the list of references, are skipped to shorten the description. I notice the term “Pons-Fleischmann effect’ in the title of Storms’ paper. Presumably this

refers to generation of unexplained exess heat. That is not the same thing as as the term "cold fusion," invented long before 1989, and defined as a nuclear process taking place in condensed matter. The two are likely to be related but this should not prevent us from saying that the P-F effects belongs to chemistry while the CF effects belong to physics. Division of labor along traditional lines is useful.

EXCESS POWER PRODUCTION FROM PLATINUM CATHODES USING THE PONS-FLEISCHMANN EFFECT

Edmund Storms Energy K. Systems,
2140 Paseo Ponderosa, Santa Fe, NM 87501

ABSTRACT
Excess power was produced using a platinum cathode. Efforts to produce active cathodes by plating palladium onto various metals were largely unsucessful.

INTRODUCTION
Palladium has been the cathode of choice since Pons and Fleischmann made their original claims. Occasionally, anomalous energy has been claimed to result from other elements such as Pt[1; 2], Au[3], Ti[4]. Thin layers of palladium on various inert substrates have also been claimed to produce anomalous energy [5; 6; 7; 8]. From this collection of experience, one might conclude that any layer of Pd made to stick tightly to the surface of another material would produce energy with greater ease than the bulk metal. This assumption has been found to be false even though such material can achieve a D/Pd ratio greater than 1.5[9]. Layers of electroplated Pd can be just as difficult to reproduce as bulk material. Although several successful samples were made, this paper will describe only one example of uncoated platinum which produced excess energy after being electrolyzed for an extended time in $LiOD+D_2O$.

EXPERIMENTAL

Calorimeter Design:

The calorimeter, shown in Fig. 1, consists of a Pyrex glass cell surrounded by a watercooled jacket. This assembly is contained in a vacuum dewar, thereby allowing most of the energy lost through the lid to be picked up by the cooling water. A magnetic stirrer is used to stir the electrolyte, thereby reducing temperature gradients.

(1*) AT WHAT RATE WAS THE LIQUID HEATED BY THE STEERER?
(2*) WHY SHOULD I ASSUME THAT IT WAS A NEGLIGIBLE RATE IN COMPARISON WITH THE EXCESS POWER (EP~ 0.1 W)?

Since the stirrer was used at the same rate for active and calibration runs, it shouldn't matter. I imaging the heating effect of the stirrer is difficult to measure, since most of the power generated by the driving electromagnet is wasted elsewhere.

The entire assembly along with all reference resistors is contained in a constant temperature environment. Table I lists

values and uncertainties for the various quantities. The electrolytic cell contains three linear thermistors within the electrolyte, one near the top of the solution, one near the bottom, and the third just above the cathode. The anode is equidistant (0.5 cm) from the flat plate cathode (1 cm x 2 cm). Temperature of distilled water flowing through the jacket is measured just as it enters the jacket and just as it leaves. Data are recorded every 15 min. using a National Instruments data acquisition system after averaging 15000 values. The flow rate is measured by allowing the water after it leaves the calorimeter to fill a container on a balance while the weight and time are recorded every 120 sec. In addition, the cell contains a Pt-coated-carbon recombiner catalyst

(3*) TO "RECOMBINE" MEANS TO MAKE H_2O FROM H_2 AND O_2 THAT ARE PRODUCED IN THE CELL. (AN EXOTERMIC PROCESS).

Absolutely. Since an electrolytic cell generates hydrogen and oxygen gas while operating, there can be alot of argument about how much heat was lost (the chemical energy, possibly the latent heat of vaporization, etc). That makes a Pin vs Pout comparison very suspect. By recombining any gases produced, the energy stays in the calorimeter. It makes the equipment more complex, but the understanding simpler.

and an exposed Pt wire heater for calibration. Luggin capillaries

(4*) WHAT ARE LUGGIN CAPILARIES?

allow the voltage between a platinum reference electrode and the cathode to be measured.

(5*) WHAT IS THE THIRD (REFERENCE) ELECTRODE FOR?
(6*) WHERE IS THE ELECTRIC DIAGRAM?
(7*) WHICH VOLTAGE WAS USED TO CALCULATE THE INPUT POWER?

I'm confused by the reference electrode too. I assume the input power calculation was done correctly, but an electric diagram would be useful.

Because the cell is connected to an oil reservoir, any gas generated within the cell can be detected by weighing the oil displaced onto a balance.

(8*) WHICH GASSES WERE GATHERED IN THE CELL AND AT WHAT RATES?
(9*) WAS ANY CHEMICAL ENERGY GENERATED IN PRODUCING THESE GASSES?

The purpose of the oil is to check for failure of the recombiner. My understanding is that recombiners are very sensitive to surface contamination - any oil displaced onto the balance makes that run invalid because of recombiner malfunction.

Samples can be quickly changed or replaced by an inert cathode for calibration.

(10*) SAMPLES OF WHAT?
(11*) WHY ARE SUCH CHANGES OR REPLACEMENTS NECESSARY?
(12*)WHAT ELSE CHANGES WHEN A SAMPLE IS REPLACED?

"samples" are platinum cathodes. Because this experiment is the comparison of an active run against a control run

(rather than relying on absolute accuracies), it is critical to change the equipment as little as possible between runs. Storms has specifically designed it for changing cathodes with minimum disturbance of the setup.

Lengthy studies of inert platinum show a stability of ±75 mW.

(13*) WHEN IS PLATINUM NOT INERT?

The $24000 question in cold fusion. I would have loved to see Storms use this equipment as a tool to study just that question. Probably, he has, but hasn't come up with a definitive answer. My biggest complaint with this experiment is the circular argument: "this sample is inert" because it had a low Pout reading, and "this sample is active" because it had a high Pout reading. The excess heating claim is made by selecting runs based on the results. Ideally, you should specify your run as calibration or active beforehand, then compare the results to prove excess heat.

Calibration and Error

A typical calibration for the flow-mode is shown in Fig. 2, using a clean piece of platinum for the cathode.

(14*) WHAT IS FLOW MODE? WHAT ARE OTHER MODES?
(15*) TO CALIBRATE USUALLY MEANS TO ESTABLISH A RELATION BETWEE TWO OR MORE VARIABLES. WHAT VALUES ARE INVOLVED IN THIS CALIBRATION?

There are two possible measurement modes that can be made with Storms' calorimeter: flow mode and isoperibolic. Storms compares them in this review.

Isoperibolic mode means this: the calorimeter cell is surrounded by a constant-temperature jacket. The thermal conductivity "U" from the heat-generating device to the jacket should not change. You graph the temperature of the inside of the cell vs Pin. Pout is U(Tinside - Tjacket). (See eqution 5.4 in this paper.) The benefit of isoperibolic mode is that it is simple (just a temperature probe) and the cell is almost at a constant temperature. The drawback is in electrolytic cells: as you increase the power, more hydrogen and oxygen bubbles are produced. This drastically reduces the thermal conductivity.

The flow mode is: measure the flow of water, and the temperature of in-flowing water and out-flowing water. Any dependence on constant thermal conductivity is removed. However, you are now very dependent on the heat capacity of the water not changing.

"Calibration" here really means control run. You plot Pin (electrical measurement) vs Pout (heat flow out of the water) on a graph for your inert platinum cathode. You haven't really "calibrated" anything in the normal sense of the word - as in making sure a measured value is traceable to some NIST standard. You've just characterized the behaviour of the calorimeter with one cathode ("inert") for later comparison with another cathode.

Values are taken both going up and going down in applied power in the same manner as the sweeps described later. The standard deviation of the electrolytic values from the least-squares line is ±30 mW

(16*) WHAT IS THE “ELECTROLYTIC VALUE” (EXPRESSED IN WATTS)?
(17*) “THE LEAST SQUARES LINE” OF WHAT VERSUS WHAT?

The graph of Pin (electrical) vs Pout(heat flow in water) should be a straight line. Also, for a perfect calorimeter, (100% heat collection efficiency) the slope should be 1W/W.

Storms generated heat inside the calorimeter in two ways for his "calibration" runs: with a simple resistor, and with the inert cathode. The simple resistor obviously doesn't generate hydrogen and oxygen gas (I think he calls these the joule-heating values). The graph for the inert cathode does generate gases: this data is the electrolytic values and is the data he uses for comparison.

If the graph of Pin vs Pout was not a straight line, Storms would have to explain why is calorimeter changed in behaviour from one power level to another. His statement of ±30 mW least squares fit simply says that the calorimeter did not change performance from an ideal one (except for the fact that the slope was 0.98W/W rather than 1).

Note thate the Pin vs Pout graph was done on values going up in power, and going down in power. This is because one could say that chemical energy is being stored in the electrolytic cell at some point, and what looks like excess heat is actually just the release of the stored energy. The Pin vs Pout graph lies on a nice straight line going up in power and down: energy storage would cause hysteresis (the up and down lines would not overlap).

which is the same as the standard deviation from a constant value when stable excess energy is being observed at low applied power.

(18*) HOW WAS “STABLE EXCESS HEAT” DEFINED OPERATIONALLY?

Good question. There is really nothing "stable" or "repeatable" about cold fusion cathodes in general. Specifically, here he probably means that at constant voltage and current settings, the Pout stays constant.

Figure 1. Drawing of the calorimeter. The electrolyte is 65 ml of 0.3 N LiOD and the anode is Pt mesh. The cell lid is Lucite and the Dewar lid is expanded foam insulation. All thermistors are glass covered. Time to reach a steady temperature is 50 min.

TABLE I
Summary of uncertainties in measured quantities
Water temperature entering the jacket = 20±0.02°
Environment temperature = 20±0.03°
Flow rate = 31.00±0.05 g/min (long term variation)
Precision of current measurement = ±<0.001 A
Precision of voltage measurement = ±<0.001 V
Precision of temperature measurement = ±<0.005°
Absolute accuracy of temperature measurement = 0.1°
Stirring rate = 300 rpm ± 1 rpm
Average heat capture efficiency = 98±0.5%

(19*) WHICH VOLTAGES WERE MEASURED AND HOW WERE THEY USED?

From what I can figure out in the raw data, the voltage used for Pin is the voltage from the cathode to the anode. I'm not sure yet how the "reference voltage" fits in here. The measurement of Pin should be so straightforward that I'm not inclined to think Strorms' screwed up here. It is a bit of faith on my part, because I don't want to delve deeper.

This scatter increases to ±0.1 W at the upper limit of applied power (27 W). A zero drift as much as -0.05 W has been observed over an extended time. Consequently, changes in excess energy production are more accurate than absolute values. Good agreement between the electrolytic- and Joule-based calibrations shows that the location of heat production does not affect the accuracy of the device. Doubling the fluid flow from 22.3 g/min to 45.3 g/min caused a change in the calibration constant from 0.0732 W/degree-g/min to 0.0738 W/degree-g/min, indicating that good thermal mixing is achieved in the exiting cooling water.

(20*) WHAT WATTAGE IS USED IN THE UNIT OF CALIBRATION CONSTANT?

Wattage: the Pin (electric power) and the Pout (water flow rate and temperature in and out)

(21*) HOW WAS THE CALIBRATION CONSTANT DETERMINED?

OK. Here is the crux of the whole Storms/Shanahan discussion: unfortunately, it can't be explained without going into some detail.

The water flowed at 31 grams/minute. The heat capacity of water is 4.18188 J/g/degC at 20C. 1 Watt is 1 Joule/second. So the theoretical "calibration" constant for a flow-mode calorimeter with 100% heat collection efficiency would be 4.18188 J/gC * 31g/min * 1min/60sec = 0.069698 W/degree-g/min * 31 g/min. This is the same value Shanahan calculates for m*Cp in Table 1. **It is the value for a calorimeter with 100% heat collection efficiency**.

Storms has is an abstruse~~obtuse~~ way of presenting the calibration data, but I guess he does it because he multiplies the flow rate x (Tout - Tin) later and he wants to get Watts out.

In any case, Storms never calculates a theoretical 100% efficiency value. He gets his value of m*Cp experimentally from his graph of Pout vs Pin. Storms' value of 0.0732 W/degree-g/min to 0.0738 W/degree-g/min above corresponds to 95% to 94% heat collection efficiency.

From his two "calibration" runs with the inert cathode, Storms gets values of 0.071221 and .070892 (See Table 1 of Shanahan or, worse, go to Storms' raw data [html][txt][zip] courtesy of that 8th wonder of the world, the Wayback Machine!) which correspond to 97.8 and 98.3% efficiency. Storms concludes he has excess heat because some active cathode runs produce values like .0680 (run 4), .685 (run1), etc, (Table 1) which clearly shows that Pout has increased by a few percent, as compared to the inert cathode. Shanahan argues that .0685 is not that different than his calculated value of .069698, and concludes no excess heat. Shanahan has made the comparison against the wrong "calibration".

Because samples can be easily changed, the cathode is frequently replaced by clean platinum when the need arises to recalibrate. Good stability is shown by a scatter of only ±1.6% in the calibration constant when measured many times over three months.

Figure 2. Comparison between electrolytic and heater calibrations before and after the study using the flow method. The heater and electrolysis agree within 1.2%.

(22*) I SUPPOSE THAT DJ (SEE FIGURE 1) IS THE TEMPERATURE DIFFERENCE BETWEEN WATER-OUT AND WATER-IN. BUT WHY IS IT DJ AND NOT DT?

Confused me too, for a while. I guess delta T is for the temperature difference between the 3 thermal probes inside the electrolytic cell, and that left "delta Jacket". Confusing choice!.

(23*) IN FIGURE 2 T FOR THE TEMPERATURE “ACROSS THE JACKET.”
IS IT THE SAME AS DJ?

The cell can also be used as a rough isoperibolic calorimeter by measuring the average temperature between the electrolyte and the cooling jacket.

(24*) OK, THIS BE THE SECOND MODE OF OPERATION. (FIRST WAS THE FLOW MODE).
(25*) FORTUNATELY, I KNOW WHAT “ISOPERIBOLIC” IS. BUT MANY PHYSICISTS

ARE LIKELY TO BE CONFUSED BY THIS ADJECTIVE.

However, this method is not stable, in spite of active stirring, because of changes in the convection currents in the electrolyte and in the jacket. Figure 3 shows how the average temperature across the jacket changed between the first and final calibration using the electrolytic method and clean Pt.

Figure 3. Comparison between applied electrolytic watts and the average temperature across the jacket for two calibration runs.

Excess Energy Measurement

Figures 4, 5, and 6 show the time history for excess power (EP) production using a special platinum cathode.

(26*) WHAT MAKES THIS ELECTRODE “SPECIAL”?

Current sweeps consist of stepping the current up in value, waiting for the calorimeter to achieve steady-state (50 min), taking five values, and repeating the process.

(27*) HOW WERE THE VALUES OF EXCESS POWER (EP) CALCULATED?
(28*) THE ERROR BARS ARE GIVEN IN TABLE 1. HOW SHOULD I USE THEM TO ESTIMATE ERROR BARS FOR THE VALUES OF EP?

After reaching 3 A, the current is reduced in steps. Notice in Fig. 4 that the expected EP was achieved at 0.5 A and 1.0 A, but decayed away when 1.5 A was applied.

(29*) WHAT IS THE “EXPECTED” EXCESS POWER?
(30*) IF IT MEANS “EXPECTED ON THE BASIS OF ANOTHER REPORT,” THEN WHAT REPORT? IF IT MEANS “THEORETICALLY EXPECTED,” THEN BY WHAT THEORY?

I think "expected" is a poor choice of words and the cause of some concern that Storms is not unbiased. It sounds like he "expects" to see excess power, and then he sees it. I think the point of the statement is just that higher current (1.5A) somehow killed the excess power reaction.

A sweep taken after the decay showed very little EP. After the current was turned off for a brief time, the study was resumed in Fig. 5. Notice that the EP again gradually increased after 0.5A was applied. Sweep #3 again showed EP and this continued while 0.75A and 1.0A were applied. However, application of 1.5A again caused the EP to decay away.

Figure 4. Time history of excess power production from a Pt sample.

Once again the current was turned off. Application of 0.5 A, shown in Fig. 6, again showed EP. The calorimeter was calibrated at 430 h using the internal heater and later using an inert Pt cathode. This experience shows a consistent pattern of behavior which was repeated once again, but is not shown here. The first sweep is shown as applied current vs EP in Fig. 7. Notice that excess power is indicated by the isoperibolic method during this initial sweep, but later sweeps do not show an effect because of a change in calibration, as indicated in Fig. 3. Also notice that the excess power falls on a higher line upon reduction in applied current. Subsequent cycles, as shown in Fig. 8, produce excess power that fall on this higher line. The final relationship is linear and extrapolates to zero EP at zero applied current, in contrast to the behavior of palladium, which requires a critical applied current before EP is produced. Figure 9 shows the sweeps taken later using different numbers of values to produce the plotted average and these are compared to the heater calibration.

Figure 5. Time history of excess power production from a Pt sample.

DISCUSSION

A large average composition within the cathode is thought required to produce excess energy. Yet many researchers have failed to produce excess power after achieving large compositions, for example Nakata et al.[10]. Now, metals that do not even dissolve hydrogen are found to make excess energy. Clearly, additional variables are operating.

Figure 6. Time history of excess power production from a Pt sample.

Figure 7. Comparison between excess energy measured using flow method and isoperipolic method during first current sweep.

In the case of platinum, this study suggests that an energy-active layer of unknown composition can deposit on a Pt surface. This observation might also be related to the frequent detection of Pt on the Pd cathode after excess energy is observed. Such a layer is slow to form, which is consistent with the observed long delay in producing excess energy, and, for this sample, it is unstable. Is it possible that such a layer might be the active material in all studies, even when palladium is used?. McKubre et al. [11] also suggest that a critical layer is required to maintain the required high composition in Pd. Perhaps this is the actual active material. If this is the case, the bulk properties of palladium are only important in that they must support a critical concentration within this layer. Since palladium can easily permit loss into the metal, such material might be the worst substrate to use. Platinum, gold, and other inert materials would appear to be better choices. Use of such materials would only require forming the active layer without a need to use special batches of the substrate. If this suggestion is true, significant changes in various theories will be required.

Figure 8. Applied current vs excess power for the various sweeps, compared to Pt calibrations taken before and after the study.

Figure 9. Applied current vs excess power for sweeps using different number of values to average are compared to the heater calibration.

151) Experimental errors in excess heat

Ludwik Kowalski (6/30/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

On May 25, 2004 Richard Eskimos (who prefers to remain anonymous), referring to items #116 to #119 on this web site, asked me (via e-mail): "Has there been any further recent discussion about Shanahan and Storms' papers? I'm still skeptical about cold fusion, but I have problems with Shanahan's criticism. I'd like to know if I'm the only one to give Shanahan's paper a critical look, as opposed to all the negative attention I'm sure any pro-cold fusion paper gets." In subsequent correspondence Richard elaborated on the above. After reading Richard's messages I asked him to summarize them in the form of a new item.

What follows is the text he composed for the readers of this web site. I am happy that the form chosen for the item is the same I used in unit #117. In fact, the first half of his essay is taken from unit #117. But then Richard focuses on aspects of the Storms-Shanahan debate that escaped my attention. Richard, who is an engineer in Canada, wrote to me that he is very interested in the cold fusion debate. He emphasized that the essay "isn't intended to address the validity of Storms' finding of excess heat, only the invalidity of Shanahan's criticism of the Storms' experiment. I'm still very skeptical on platinum."

In another message he wrote: "Mr. Shanahan's general discussion of systematic and random errors on your web site is certainly factual. He proposes that Mr. Storms has not analyzed the systematic errors adequately: he is probably right, and since no budget is infinite (especially Mr. Storms'), one can always make that claim about any experiment. Also, Mr. Shanahan has the advantage in a discussion about excess energy, since the burden of proof lies with Mr. Storm. However, in his paper, 'A Possible Calorimetric Error in Heavy Water Electrolysis on Platinum', Mr. Shanahan states that Mr. Storms has made an error in the experiment. So Mr. Shanahan now has the burden of proof to show exactly what the error is - a general claim of a systematic error because of unaccounted variables is not sufficient."

As in unit #117, electrochemical nuances are skipped by discussing a setup with two cylinders (magic and not-magic) instead of discussing real electrochemical cells. The nature of what is going inside these cylinders is ignored. Is such an approach appropriate to discuss the Storms and Shanahan controversy? I think it is appropriate because the debate, as far as I understand it, does not focus on electrochemistry. I am glad that Richard found time to elaborate on comments made in e-mail messages. In one message he wrote; "If I were close to retiring, I would definitely be getting more involved."

Please note that Pin (power input) refers to the rate at which electric energy is used to run a device while Pout (power output) refers to the rate at which heat is generated in that device. Without any additional input of energy the value of Pout can not possibly exceed the Pin. In a common light bulb, for example, Pin can be 60 W while Pout is close to 57 W. The positive difference between Pout and Pin, presumably detected by many scientists, is called excess heat. Dr. Edmund Storms is one of these scientists. Dr. Kirk Shanahan, also a scientist, thinks that claims of discoveries of excess heat result from calibration errors, as described in units #116 to #119. Is he right or is he wrong? The dialog between people below focuses on that question. My comments appear at the end.

= = = = = = = = = = = = = = =

On Storms-Shanahan Controversy

Richard Eskimos

1) Student:
My friend, an electrical engineer, discovered an unusual resistor. It behaves normally when the current is low (below 100 mA); the electric power, Pin, and the heat generation rate, Pout, are practically identical, as they should be. But at a larger current the Pout exceeds the Pin. The engineer thinks that he has discovered a new phenomenon; some unknown exothermic process is triggered by the current in the material from which the resistor is made. Is this possible?

2) Teacher:
We do not know everything about nature; new discoveries are likely to be made anywhere and at any time. Your friend may indeed be making an important discovery but I am not willing to accept his claim on faith.

3) Student:
My friend has a calorimeter and other instruments. He said he is willing to make a demonstration. Would you be interested in seeing it?

4) Teacher:
Yes, I would.

5) Engineer (one week later):
Thanks for allowing me to use the laboratory. Everything is ready. Should we start collecting data?

6) Teacher:
I would prefer if you first tell us exactly what you want to do. Where is your "magic resistor"

7) Engineer (reaching in his pocket):
Actually, I have two cylindrical resistors, a magic and a non-magic. They are mechanically identical. The only difference between them is the composition of powders placed in small cavities near the centers of cylinders.

8) Teacher:
What is the nature of these powders? Is it possible that a chemical reaction producing heat takes place in one cylinder and not in another?

9) Engineer:
For the time being I can only say that powders are not consumed. In other words they are not chemical fuels. A qualified chemist verified this by examining powders before and after many experiments.

10) Teacher:
OK, we might ask other chemists to verify this. For the time being we are interested in the small amount of excess heat observed by you. Is it real or not? Small quantities of anything are difficult to measure because of unavoidable experimental errors. Tell us more about your experimental setup.

11) Engineer:
Two insulated wires are soldered to the terminals of my resistors. I will connect each resistor to a d.c. power supply and show that V/I is essentially constant (Ohm's law), at least up to I=0.3 A. The R will be close to 160 ohms. The input power, Pin, will be calculated as V*I, where V is the measured voltage across the resistor.

12) Teacher:
How accurate are your voltmeter and ammeter?

13) Engineer:
According to manufacturer's specifications the accuracy of each instrument is 0.5%. This means that the accuracy of Pin will be 1%.

14) Teacher:
And what kind of instruments will be used to measure the heating rate, Pout?

15) Engineer:
For this I have built a flow calorimeter. It is a well isolated container whose capacity is close to one liter. Water enters through the pipe at the bottom (passing through a commercial flowmeter) and exits through the pipe near the top. I will set the flow rate to about 50 cubic centimeters per minute. To measure Pout I will immerse a resistor into the calorimeter. The temperature of entering water, T_1, and the temperature of exiting water, T_2, will be measured.

16) Teacher:
How accurate are the thermometers and the flowmeter?

17) Engineer:
Temperatures can be measured with an accuracy of plus or minus 0.1^{o}C. The factory-specified accuracy of the flowmeter is 1%. The container is thermally insulated as well as possible; this means that almost all of the heat (98%) is removed from it by water.

18) Teacher:
Your goal is to determine Pout. How will this be accomplished?

19) Engineer:
I will calculate Pout from the following equation: $Pout=S*F*(T_2-T_1)$, where S is the known specific heat of water (4186 J/kg*C), F is the flow rate (in kg/s) and (T_2-T_1) is the measured difference of temperatures.

20) Teacher:
That makes sense. Will the (T_2-T_1) remain constant?

21) Engineer:
At the beginning T_2 will be the same as T_1. Then T_2 will start increasing slowly while T_1 will remain constant (room temperature). After about two hours T_2 will stop changing and (T_2-T_1) will remain constant. This will indicate that in each minute heat generated and heat removed (by circulating water) are equal.

22) Teacher:
How accurate will be your determination of Pout?

23) Engineer:
The difference of temperatures will be about 10 ^{o}C. Thus the accuracy of the (T_2-T_1) term will be slightly less than 1%. To be on the safe side I will assume it is 1%. The accuracy at which F will be measured, as I said before, will be 1%. In other words, Pout will be known at the accuracy of 2%.

24) Teacher (addressing students):
Let me make a comment. Our guest is using the word "accuracy;" rather than the word "precision." This is correct. The word "precision" should be used when we are referring to random errors while the word "accuracy" should be used when we are referring to systematic errors. Suppose Pout turns out to be 40 W. Then, knowing that the accuracy is 2%, we would be able to say that the "true value" of Pout can be anywhere between 39.2 and 40.8 watts. Unlike random errors, which may also be present, systematic errors can not be reduced by performing the same experiment many times to obtain the average value. Let me make sure I understand you correctly. You will show that Pout is larger than Pin by

the amount that is significantly larger than experimental errors. Is this correct?

25) Engineer:
Not exactly. I would do this if the difference between Pout and Pin were large, for example, larger than 10% of Pin. My approach is different. I will keep the Pin constant and compare the values of Pout for my two resistors. I will do the experiment a number of times with the non-magic resistor, and a number of times with the magic resistor. Then I will compare the results. This means that I am less concerned about the accuracy of my equipment. I am much more concerned about the stability. If my equipment has a systematic error, I want it to have the same systematic error for both resistors. My sensitivity to excess heat now depends on the stability and precision of my equipment (and on how small a change I introduce in switching resistors).

26) Teacher:
I think we should continue discussing your data, with that in mind. How large were the actual values of Pout and Pin for the two resistors?

27) Engineer:
I've kept Pin at 36.4 W for both resistors. Pout for the non-magic resistor turned out to be 35.76W. Pout for the magic resistor turned out to be 36.76W. To me it means that the difference between these two numbers, 1 W, represents the "excess power." It is the rate at which thermal energy is generated inside the calorimeter. I think that this happens through a new nuclear process. What else can it be?

28) Teacher:
I can think of many non-nuclear processes able to generate heat at the rate of 1W. But that is not the issue here. Our goal is to establish reality of excess heat (~ 1 W) and not its origin.

29) Another student, Kirk Shanahan, makes a comment:
I notice that for the experiment with the magic resistor, Pin is 36.4W and Pout is 36.76W. The difference is much less than 1W. In fact, it's 1/3W, less than 1%. I think you have no excess heat, just experimental error.

30) Teacher:
Mr. Shanahan raises a very good point, but before we get to it, I want to know a bit more about the experimental errors. Firstly, about accuracy. Is it possible that the difference of 1 W is nothing but an experimental error due to the limited accuracy of measurements? We know that the true value of Pout can be anywhere between 35.96 and 37.56 W. That is based on your 2% accuracy. Likewise, the true value of Pin can be anywhere between 36.0 and 36.8 W; this is based on your 1% accuracy. Thus, the difference between Pout and Pin, can be as small as -0.84 W or as large as 1.56 W. Do you understand my reservations?

31) Engineer:
Yes. I agree that my equipment could be giving inaccurate values of Pin and Pout. I expected it. That is why I compared a non-magic and magic resistor. If my equipment is reading Pin at 2% too low, I don't mind. I just want to be sure that the reading is 2% too low for both the non-magic and the magic resistor. My first concern was that it might read 2% too low in the morning for the non-magic resistor, and accurate in the afternoon for the magic resistor. So I repeated the run with the non-magic resistor many times, at different times of the day. I also removed and reinstalled the resistor and compared readings. I found that the Pout readings varied by 0.3% over all of these runs. Likewise, the Pin readings varied by no more than 0.1%.

32) Teacher:
From these repeats, you don't know if the readings are all about 2% too low. And as long as that inaccuracy is the same for both resistors, you don't care. Is this your main point?

33) Engineer:
Correct, as long as it is the same for both resistors, I don't need to know how far off I am.

34) Teacher:

So, after these runs, you found that your Pout readings were repeatable to 0.3%. Let's go into the details of the runs. In runs with the non-magic resistor, Pout was 35.7W: on average; an individual reading could have been as low as 35.5 and as high as 35.9W. Similarly, Pin readings could have been anywhere from 36.2 to 36.6W. So, the difference Pout - Pin was from -0.3 to -1.1W. Shouldn't it have averaged out to zero? This sounds like the non-magic resistor is not behaving perfectly.

36) Engineer:
Correct - the equipment is not perfect. I believe the non-magic resistor has Pout = Pin, but the calorimeter is imperfect. The Pout I measure is the power collected by the water from the resistor. Not all the power out of the resistor goes into the water. Some of the power is conducted up the resistor's metal leads into the room. Since it doesn't go into heating the water, I don't measure it. This is a parameter of all calorimeters called the heat collection efficiency. I measure my heat collection efficiency to be 98%. (Pout = 35.67W is 98% of Pin = 36.4W). I have to work within that practical limitation and remove any error it causes if possible.

37) Teacher:
OK, let's look at the magic resistor results. Pout was 36.76W and Pin was 36.4W. With 0.5% error, the range for Pout is then 36.58 to 36.94W. The range for Pin is still from 36.2 to 36.6W. This reminds me of Mr. Shanahan's comment. In this experiment, it could have been possible that Pout and Pin are both 36.6W. Then you would have Pout = Pin and no proof of excess heat.

38) Engineer:
True, based on the assumption that my calorimeter just achieved a heat collection efficiency of 100%. There are two problems with that assumption. One, a 100% efficient calorimeter is difficult, if not impossible, to build. Two, in my non-magic resistor experiments, I measured that my calorimeter is 98% efficient. In order for that assumption to be plausible, you would have to show that changing resistors changed my efficiency. This is not likely to occur; my resistors are essentially identical, as far as the geometry is concerned. I've made the two resistors as mechanically identical as possible and their location in the calorimeter does not change. The electric leads are of the same material and the same gauge. The heat escaping out should be the same. I've removed and replaced the non-magic resistor several times, and the heat collection efficiency did not change.

39) Student Shanahan:
I have another comment. Based on the heat capacity of water and the flow rate, I've calculated a theoretical value for the ratio Pout/Pin. I'm looking at your data for the various runs. I've calculated Pout/Pin for each run. I see that the ratios for the magic resistor runs are clustered near my theoretical value. This leads me to conclude you have no excess heat. I also see that the ratios for the non-magic resistor are clustered at a value 2% lower than my theoretical value. This leads me to conclude that the non-magic resistor experiments have a systematic flaw - I don't know what it is. Possibly all calorimeter experiments have this flaw.

42) Engineer:
Your theoretical value for the ratio Pout/Pin is calculated for equipment that is perfectly accurate and a calorimeter that has 100% heat collection efficiency. A conclusion based on such unrealistic assumption should not be taken more seriously than conclusions based on my experimental data. I did not idealized anything. Is it not obvious?

43) Teacher:
Yes. The theoretical calculation of Pout/Pin does not have a systematic experimental error. You can't compare the experimental ratio to the theoretical ratio on the 0.5% scale, only as a rough estimate of how large your systematic errors are (which we think is 2%). On the other hand, comparing the non-magic and the magic resistor experimental values to each other allows us to ignore systematic errors which are stable. Thus the 1W difference between the values of Pout seems to be real.

44) Engineer:
I'd like to add that, if my equipment is accurate, the fact that the non-magic resistor measurements are clustered at 2% lower is simply a repetition of my previous statement that the heat collection efficiency is 98%.

45) Teacher:
Since I get the last word, I'd like to say that an experiment which compares the test of the hypothesis against an almost-identical control (or calibration) test has a sensitivity higher than the accuracy limits. Shanahan's suggestion that the magic resistor results should only be compared to a theoretical value rather than to the non-magic resistor isn't correct. The key to making the experiment convincing is to make the difference between the two experiments as small as possible. In this case, the engineer has designed the resistor to be swapped out very easily, which is an advantage. As always, the findings must be confirmed by others. Would you be willing to reveal the compositions of your powders to other scientists?

46) Engineer:
I would, but first I must protect myself with a patent. I do have a family to support; the discovery may lead to practical applications.

47) Teacher:
I understand. This is an important social issue but I do not think that we should debate it here. For the time being I would say that your claim for the discovery of excess heat is credible. Process your patent as quickly as possible and reveal the composition of your "magic powder," preferably in a reputable scientific journal. This might become an important scientific contribution without leading to immediate practical applications.

P.S. Comments (by Ludwik Kowalski):

1) It is a pity that Richard Eskimos asked me not to show his real name. Will the pending DOE evaluation of cold fusion end the unhealthy situation in which discussing cold fusion is dangerous to young scientists? I hope it will. Declaring that cold fusion is not different from any other area of science, and that additional research in that area is welcome, is the first thing that the new DOE panel should do. In saying this I am assuming that no evidence of fraud, or incompetence (among the major players), will be discovered.

2) Let me compare the proposal presented by the inventor (Engineer) in Unit #117 with the proposal presented by him in Richard's essay. The goal, in both cases, is to measure x=A-B, where x is the excess power while A and B are two numbers much larger than x. In the unit #117 the value of A (output power) was determined calorimetrically while the value of B (input power) was determined electrically. This approach failed to demonstrate that x is positive because of large uncertainties (systematic errors) in the values of A and B. The approach would not fail if x was several times larger, or if more accurate instruments were used to measure A and B.

In Richard's story the inventor decided to take a different approach. The value of x is determined not by comparing A and B but by comparing two different values of A. One value, A', is determined by using the "magic" resistor while another, A", is determined by using several control resistors. All resistors are geometrically identical; each contains a tiny cavity at the center. In control resistors that cavity contains sand but in the active resistors it contains a sand-looking "magic powder." This implies that heat collection efficiencies (~98%) are practically the same in all experiments.

In this new context x=A'-A". A systematic error in measuring A' and A" can be tolerated, as long as it is practically the same for both A' and A". The issue, as stated in voice #25, is no longer the magnitude of the systematic error, the credibility of the discovery depends on the stability of errors. Here is how I would summarize the issue. If the calorimetric error (about 2%, as in unit #117) changes significantly, when the magic resistor is replaced by a control resistor, then Shanahan is right. If, on the other hand, such change is very unlikely. then Storms is right. Is this the crux of the controversy?

3) Let me end with an interesting observation that Richard made when he saw the draft of this document (without my comments at the end). That observation was mostly about unit #148 but will append it here. Richard wrote:

I think the file is ready for posting. Having said that, I do have some philosophical issues with this approach (this is just for discussion purposes - don't let it prevent you from posting the file). This teacher/engineer essay is self-contained, so it re-states the essences of Storms' and Shanahan's papers - that makes it too long. At the same time, there is only room

for the high points of each paper - so the essay leaves the field wide open for Shanahan's rebuttals. I don't know how to get around these two issues in a better way, if the essay is intended for a general audience.

In your previous topic, you lamented the fact that scientific papers are much more abstruse than they need to be. It's exactly for these two reasons that it happens: the authors want to cover all the possible future rebuttals, so as not to cause lengthy debates. That makes the paper long and detailed. To compensate for the extra length, they refer to previous papers and the jargon of their field in abbreviated form. That makes reading the paper laborious for anyone who is not familiar with the previous papers.

I think scientific paper writing needs to get into the computer age. A scientist wishing to be accessible could write the "main" paper as they do now, for other scientists. If she wrote it in html, she could incorporate hypetext links. Jargon could be linked to definitions/descriptions; citations to other papers could actually hyperlink to those papers (maybe even the relevant sentences in the paper); calculations (which are often "left for the student") and data files could be linked to, in all their gory detail.

(Comment: Storms' paper originally linked to his data files, and that is how Shanahan analyzed his paper so fully. I found the original data on the Wayback Machine. Without access to the data, Storms' paper is much harder to get a clear picture of.) I don't know why papers aren't written this way, except that most journals are in hardcopy form.

152) Recent cold fusion claims: are they valid?

Ludwik Kowalski (6/28/04)
Department of Mathematical Sciences
Montclair State University, Montclair, NJ, 07043

Introduction

Cold fusion (CF), presumably discovered 15 years ago, is any process in which a nuclear reaction is produced without relying on traditional means, such as particle accelerators, neutron sources, cosmic rays, alpha particles or stellar temperatures. In 1989, several months after the discovery was announced (through a press release at the University of Utah) a panel of scientists, appointed by the US Department of Energy (DOE), examined the evidence supporting the CF claims. That evidence was declared insufficient. But, as summarized in[1] "there remain unresolved issues which may have interesting implications. The Panel is, therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system."

CF became highly controversial and only several hundred researchers continued working on it, world-wide. Most scientists still think that cold fusion is pseudoscience. On that basis editors of many journals refuse to publish papers devoted to CF research. Only a small fraction of scientists is familiar with recent progress in the area. The purpose of this article is to objectively summarize recent findings[2] and to supply references with which I am familiar. The article was triggered by the reported initiative of DOE to review[3,4] cold fusion research. I will focus on four cold fusion claims which are, in my opinion, the most important. As a nuclear physicist, and a physics teacher, I examined many CF publications and attended one cold fusion conference[5].

Claim #1: unexpected emission of nuclear particles

In the early 1980's Steven Jones, working at the Los Alamos National Laboratory, explored muonic atoms of hydrogen and the unstable molecules they form[6]. Such molecules are about 200 times smaller than their stable electronic counterparts. According to a well verified theory of the so-called "tunneling effect," the proximity of hydrogen atoms in muonic molecules increases the probability of nuclear fusion by many orders of magnitude. This is associated with the release of energy, as in stellar interiors and hydrogen bombs. For nearly a decade the work on muonic atoms was supported by the US government as a possible path toward a new source of energy. The grant, however, was not renewed after it became clear that practical applications, if any, would not materialize in the immediate future.

These investigations led to the idea that cold fusion might be occurring at very high pressures inside planets, as described in[7,8]. The notion that guides Jones, of a large electron screening effect in the D-D fusion reaction for deuterons embedded in metals, has been independently confirmed by other experimental physicists[9,14,15]. Can screening be responsible for lowering of the D-D coulomb barrier in a metal? Recent observations of rare neutrons and charged particles, reported by Jones[10], give credence to such speculations. The rates of observed emission are usually very low but significantly higher than the background; in one experiment the rate of proton emission was 400 times higher than the background.

The particles, identified as 3 MeV protons, were emitted from spots inside thin titanium foils loaded with deuterium. To load hydrogen ions into the foils Jones placed them (for several hours) into a cylinder filled with deuterium gas at elevated temperature (500^{o} C) and pressure (40 psi). Emission of nuclear particles was subsequently recorded with scintillation and silicon detectors in the low-noise environment. An aluminum foil of 19 microns helped to identify charged particles as protons. Coincidences between protons and other charged particles (tentatively assumed to be ^{3}H) were observed with a set of two silicon detectors. It is worth adding that protons and alpha particles have also been

reported by A. Lipson[11], R. Oriani[12] and A. Karabut[13]. These researchers worked independently of each other; their methods of loading metals with ions, and their methods of particle detection, were very different from those used by Jones.

The process of emission of such particles remains to be interpreted. For the time being Jones favors the model according to which the 2.45 MeV neutrons and the 3.02 MeV protons are accompanied by 0.82 MeV ^{3}He and by 1.01 MeV ^{3}H, respectively, as in well known thermonuclear reactions. The probability of emission of these particles in a metallic environment, however, is much higher than in hot plasma. A recent paper, published by a team of German scientists[9], does show that the cross section of the D(d,p)t reaction, at very low energies (down to 5 keV), is about one order of magnitude larger in the deuterated Ta than in a gas target. Similar observations were made earlier in Japan[14,15]. Very recently, a team of researchers, from Russian Academy of Science[16], found a unique way of observing protons (presumably from the same reaction) down to the energy of 0.8 keV. The observed rate of emission, at the lowest energy, turned out to be nine orders of magnitude higher than predicted by an accepted theory. This seems to indicate that the theory which agrees with experimental data above the energy of 10 keV fails to account for what happens to the embedded ions in titanium at much lower energies. But arguments about a model (screening versus other possible explanations) should not be confused with arguments about the validity of experimental data (observing unexpected neutrons protons and tritons).

Claim #2: accumulation of 4He in excess heat experiments

The claim of excess heat was first made in a famous press conference, on March 23, 1989. That event, and its consequences, are described in several books about cold fusion[1,17,18,19,20]. Two scientists, M. Fleischmann and S. Pons, announced that they had been conducting research on highly unusual electrochemical cells for several years. These cells were said to be outputting more thermal energy than received in the form of electric energy. The authors wrote that chemical contributions to excess heat were found to be insignificant. On that basis they tentatively concluded that the origin of excess heat was nuclear. Rejecting this hypothesis the critics pointed out that rates of nuclear reactions accompanying excess heat, if the origin of that heat were nuclear, would be many orders of magnitude higher than what was observed. Fleischmann's research, prompted by theoretical considerations[21], was purely experimental. The arguments against it, however, were based on the theoretical model of tunneling effect. The critics assumed that nuclear reactions, presumably responsible for excess heat, should be the same as those in hot plasma. Difficulties reproducing the effect also contributed to initial skepticism.

Subsequent work in the area is described in two books[22,23] and in many papers, such as[24,25]. The authors of these references describe experiments in which excess heat was generated. But they do not always provide enough data to rule out the possibility that a large fraction of excess heat can be due to parasitic chemical reactions, or other non-nuclear processes. Furthermore, according to Shanahan[26], the excess heat claims are due to calibration errors. It is difficult to accept this accusation because similar results have been reported by a large number of highly qualified scientists in several countries. On the other hand, one should not ignore the possibility of experimental bias, mutual self-deception, or even fraud. The best evidence that the excess heat is nuclear would be to show the commensurate accumulation of byproducts of nuclear reactions, such as ^{4}He. This will be addressed in connection with claim #4 below.

The most recent contribution, in the area of excess heat, belongs to a group of Chinese scientists[27]. X. Li, a veteran of cold fusion research, did not use electrochemistry to load palladium with deuterium. The excess heat was generated when compressed gas was allowed to diffuse through a thin palladium wall. According to the authors, that heat could not be explained by the well known Joule-Thomson effect or by chemical reactions. They write: "this experiment has been repeated 6 times already in various configurations. The 'excess power' density in the Pd disk is more than 100 W per cubic centimeter, which is about the power density in a fuel rod of a thermal neutron fission reactor." Reproducible results on generation of excess heat, in a glow discharge chamber (another non-electrolytic method of loading metals with D^+ ions), were also reported by Russian scientists[13].

Generation of excess heat without producing radioactive material would certainly be desirable. But how can nuclear energy be released without commensurate amounts of radioactivity? According to some theoretical considerations[27],

deuterium ions embedded in crystals might be influenced by a large number of atoms able to supply and to remove energy "in unison". Theoretical modeling of natural phenomena, however, and attempts to validate these phenomena experimentally, are two different things. Arguments for or against models do not resolve disputes about validity of experimental data.

Claim #3: highly abnormal isotopic ratios

Chemical elements, not initially present, often accumulate in cold fusion setups, as reported in[13, 22, 29, 30]. Are new chemical elements due to nuclear reactions or are they impurities introduced during various manipulations? The most direct way of answering this question is to subject the residual chemicals to isotopic analysis. Such analysis shows that isotopic compositions of residuals are often very different from those expected from contamination. According to[13], for example, nickel found in a palladium cathode (after the cathode was used to generate excess heat) contained less than 1% of ^{58}Ni; the natural abundance of that isotope is nearly 68%. On the other hand, carbon found in the cathode contained 20% of ^{13}C, while the natural abundance of that isotope is about 1%. Similar results were reported by other researchers[22,30]. Such findings, if confirmed, would indicate that nuclear processes do take place in some CF setups.

Claim #4: nuclear transmutations

Absence of anticipated products (unjustifiably expected to be the same as in well known thermonuclear reactions) was often used as an argument against cold fusion. A thermonuclear fusion of two deuterons (^{2}H + ^{2}H), for example, nearly always results in production of either ^{3}He or ^{3}H (associated with the emission of neutrons and protons, respectively). Absence of commensurate amounts of neutrons and protons, in excess heat experiments, was often compared to fire without any ashes. That is why the claim of nuclear origin of excess heat was not taken seriously when it was first made in 1989. But several years later progressive accumulation of ^{4}He was reported by several investigators[31,32]. The authors found that helium generated via cold fusion is mainly ^{4}He; the ^{3}H and ^{3}He atoms are produced much less frequently. The situation is dramatically different from what happens in thermonuclear reactions taking place in ionized gasses. In these reactions the probability of the ^{2}D+^{2}D--> ^{4}He (releasing about 24 MeV of energy) is 10^{-6} while the probabilities of reactions producing ^{3}H and ^{3}He (releasing about 3 MeV of energy) are roughly 0.5 each.

Furthermore, the energy released in cold fusion (24 MeV per dominant cold fusion event) appears in the form of heat and not in the form of gamma rays (as in rare hot fusion events). How can such differences be explained? That is one of the many unanswered theoretical questions. At present, however, the main issue is experimental rather than theoretical. Is the accumulation of ^{4}He, at the rate of about one atom per 24 MeV of excess heat, real or apparent? Skeptics suspect that helium comes from the surrounding air and not from a totally unexpected nuclear reaction. The authors of the above mentioned reports, however, addressed this issue and ruled out the possibility of atmospheric contamination. If confirmed, such findings could become very significant. They would indicate that ^{4}He is the main "ash" of the mysterious CF "burning," at least in some cases. Those who objected to cold fusion claims in 1989 expected ^{3}H and ^{3}He to be dominant ashes; how would the discovery of cold fusion have been received if information about ^{4}He was available at that time?

As it turned out, ^{4}He, is not always a dominant "ash" accumulating in excess heat experiments. Production of elements heavier that helium, first reported and then withdrawn by Bockris, was later heralded by some investigators[13,22,33]. Results from a very extensive study are summarized in [34]. The most recent report in this disputed area was presented by Iwamura, from Advanced Technology Research Center, Mitsubishi Heavy Industries, Ltd., in Japan. Addressing the 10th international CF conference (August 2003) Iwamura described a fascinating setup[35] in which cesium was turned into praseodymium and strontium was turned into molybdenum. The paper describing these experiments[36] had already been published in the Japanese Journal of Applied Physics (JJAP). It is highly significant that the isotopic composition of Mo, produced from Sr, is drastically different from that found in nature. This seems to rule out the possibility of contamination (redistribution of impurities). Low energy transmutations in condensed matter, reported by Iwamura, have been repeated by scientists from Osaka University[37].

Final Comments

Cold fusion is not taken seriously by most scientists. But, according to my own informal survey, the opinion of many is still based on what was known in 1989 and not on recent findings. I think that the often repeated labels, such as "pseudoscience" and "fiasco of the century" were perhaps justifiable in 1989, when the first DOE review was conducted. But are such labels justifiable today? Most of us are not equipped to answer this question through laboratory investigations. That is why another official evaluation is desirable. Are the credentials of CF scientists doubtful or not? Are their ways of validation consistent with scientific methodologies? Is there any evidence of deliberate deception? Answers to such questions should help us decide what to think about the controversial field, and what to tell students when they ask questions about it.

Cold fusion claims have often been criticized for being in conflict with the existing theory of nuclear phenomena. Reacting to this one can say that in science a theory should guide while experiments should decide. That is a recognized principle of our scientific method in which theories are models of objective reality. Models often lead scientists to discoveries of new facts but a single confirmed fact contradicting a model is a good reason to modify a theory. On the other hand, an established theory, one that is not only logically consistent, but is also supported by a large number of experimental facts, has a special place in the arsenal of scientific tools. Leaning on such theory is like leaning on the experimental facts supporting it. A theory often protects us from drawing wrong conclusions from experimental data. The initial skepticism about cold fusion was mostly based on the accepted theory; it was not based on critical analysis of new data. The cold fusion controversy, no matter how it is resolved, offers us an insight into the delicate interplay between theoretical and experimental investigations.

I have already written about rejections of cold fusion papers by editors (see item #88); this item describes my experience trying to publish a cold fusion review paper (item #152). What follows are dated entries and messages, as recorded during the Spring 2004 semester. I present them in the form of a diary; colors are used to identify e-mail messages. The editors of the following journals rejected the paper without sending it to referees and without offering any criticism:

```
1) Physics Today, USA
2) American Scientist, USA
3) Nature, UK
4) New Scientist, UK
5) The Physics Teacher, USA
```

THIS DIARY-LIKE ITEM IS UNREASONABLY LONG. READ THE ITEM #154 INSTEAD, UNLESS YOU ARE INTERESTED IN IRRELEVANT DETAILS.

153) Why was my review paper rejected?

Ludwik Kowalski (6/29/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

A SHORTER (BETTER) VERSION OF THIS IS IN ITEM 154

2/11/04
What to think about this e-mail message (in green, below)? It refers to what was described in my unit #100; the rejection of my Letter to the Editor of Physics I considered the rejection final. That is why I am so surprised. And what a coincidence; I just finished working on a paper objectively summarizing the situation in the cold fusion field and I am looking for a place to publish it. What would be a better place for it than Physics Today? Should I consider the message from Dr. Hanna to be an indication that this might be possible? Why did she write to me after the issue was essentially over about half a year ago? I do not know how to answer this question. Here is a message I received today:

Dear Dr. Kowalski,

In August of 2003, you submitted a Letter to the Editor commenting on our previous rejection of a letter you'd sent to us last January. That earlier letter commented on the story, "New APS Ethics Guidelines Address Research, Misconduct and Professional Responsibilities."

Please accept my sincere apologies that we have taken so long to get back to you. We did give both of your letters careful consideration.

After that consideration, it was decided that we would share with you the reviewers' comments on your first letter. Those comments are contained in the attached MS Word file. Please let me know if you have any problem opening or viewing the file.

Also please note that your second letter was not accepted for publication. While we do appreciate and carefully review letters about how we are doing our job, we consider them to be internal business.

If you have further concerns about this matter, you may contact me via e-mail at ptletter@aip.org or telephone at 301 209-3041. My fax number is 301 209-0842.

Thank you for writing and for your interest in Physics Today.

Sincerely, Marty Hanna, Letters Editor, Physics Today, College Park, Maryland.

Here are the reviewer's comments from the attached file.

Reviewers' Comments on Ludwik Kowalski's Letter

Reviewer 1: I don't have a high opinion of this letter. The author is trying to use the ethics guidelines as a wedge to say that cold fusion scientists are doing real science and are being discriminated against by the science establishment. It is, at its base, a polite dance around the cold fusion conspiracy theory. He notes that the "new" work with cold fusion may not be fusion, but some other mystery that seems, despite all of the work, somehow beyond the understanding of the scientists. And even though it may not be fusion, or just a little bit fusion, the respected science journals discriminate against the work. I get the impression the author isn't a cold fusion scientist with an axe to grind, but it sounds like he's been to a few seminars with them. I recommend against publishing this as it does nothing but revive a conspiracy theory that is better off dead.

Reviewer 2: Reject. I'm actually a bit ambivalent — his concern as a teacher of students seems valid. If you want, get another opinion from our staff teacher.

Reviewer 3: I'm comfortable with the reject but, like Reviewer 2, see some merit in the Letter. I believe it raises a legitimate discussion point: what is the physics community's responsibility, if any, to sincere, competent workers who choose to explore "fringe" fields like cold fusion. Harold Birnbaum touched on this issue in his March 2002 article for us, when he noted his impression that nowadays, reviewers are less likely than previously to support a proposal that is not in accord with their own view. It could be argued that the question is an ethical one, so I find it reasonable that Kowalski's letter was inspired by Jim Dawson's ethical-guidelines report.

Kowalski's letter is not well focused, and as a result, Reviewers 1 and 2 and I each took something different from it. Kowalski's choice to limit his letter to cold fusion instead of addressing a larger picture was unfortunate, in my opinion. Reviewer 1 decided that the letter "does nothing but revive a conspiracy theory that is better off dead." I think the letter hints at more, but Reviewer 1's take is certainly reasonable, given what the letter actually says. In brief, if I were the first to look at this letter, I would consider working with the author (and it would take some work) to try to get the letter I think the author intended. However, as an "appeals judge," I see no reason to overturn the decision of the "lower court."

= = = = = = = = = = = = = = = = = =

Here is my immediate reply:
Dear Dr. Hanna:
I am very glad that you decided to share with me what reviewers wrote about the Letter to the Editor I wrote one year ago. Let me comment on what they wrote and then make a suggestion.

1) Yes, the first reviewer was correct that I was "trying to use the ethics guidelines." Referring to me he wrote: "it sounds like he's been to a few seminars with them ['cold fusion scientist with an axe to grind']." This was not true when my letter was written; at that time I was mostly interested in moral aspects of the cold fusion episode. But I did go to a cold fusion seminar last August and participated in the 10th International Cold Fusion Conference. I went there as an

open minded teacher and I learned a lot.

2) I am pleased that two of three reviewers did “see some merit in the letter.“ That shows that a conspiracy, if it exists, is not widespread. And your decision to share the comments with me is a confirmation of this.

3) It happened that I just finished writing a paper about basic recent claims made by leading cold fusion scientists. It is not a paper defending these claims; it is a paper describing them, no matter what one is inclined to think. Scientifically literate readers should be aware of what has been going on in the cold fusion field since it was officially evaluated, in 1989, by a panel of US experts. Some of the new claims, such as turning Sr into Mo, or Cs into Pr, without stellar temperatures, are even more extraordinary than the claims made by Pons and Fleischmann. The strange thing is that authors of published alchemy reports seem to be reputable scientists associated with prestigious universities and laboratories. Is it a matter of fraud? Is it a matter of self-deception, or incompetence? My article does not try to answer these questions; its purpose is to present a summary of what has been recently reported without taking sides. Like many other science teachers, I am in no position to verify validity of hard-to-accept claims in a specialized laboratory. That is why, as suggested in the concluding section, a new evaluation of cold fusion claims, by an appointed panel of experts, is highly desirable.

4) Anticipating that my article would be rejected in the US I considered publishing it abroad. But I would very much prefer to publish it in our journal, Physics Today. What I write is likely to generate interesting discussion and comments. A copy of that paper is attached. Please pass this message to the Editor-in-Chief and let me know if the journal is willing to send it to reviewers. Sincerely yours, Ludwik Kowalski

P.S. Last year I spent my entire sabbatical collecting cold fusion documents, and reading them. I did this for myself and for others who are not familiar with recent cold fusion claims. Many readers of Physics Today will probably appreciate my summary. What kind of harm can possibly result from publishing it?

= = = = = = = = = = = = = = = = = =

The manuscript that was attached can be seen in item #152 on this web site. The answer to my reply came two hours later, much faster than I expected. Here it is:

Dear Dr. Kowalski, Thank you so much for your feedback, and thank you for the article submission. Because the document you sent is beyond the limits of the Letters Department, I have forwarded it to our editorial staff for consideration as an article. Please send further inquiries about it to pt@aip.org, but expect that it could be several weeks before you hear from our editors. With gratitude and kind regards, Marty Hanna
Letters Editor, Physics Today, College Park, Maryland.

= = = = = = = = = = = = = = = = = =

What to think about all this? Why the apology, six month later? Will they give my paper a chance to be reviewed by unbiased people? I do not know how to answer these questions. I suspect that my registered letter to the Editor in Chief, mailed in September was finally read and acted upon. I can not locate the copy of what I wrote but I do remember complaining about not being able to see the comments made by reviewers. At the end of that letter I suggested that its content should be treated as a second Letter to the Editor. The Editor in Chief never replied to me. Perhaps he remembered my earlier complaints. What else could have triggered this new message from Dr. Hanna? If they publish my article I will be very happy, if they do not publish it then I will have another record of rejection. Such records are worth saving; I should be able to find an editor willing to accept my review. If not then the review will appear as an item on this web site. For the time being I will withhold this item; it is probably not right to make it available and try to publish it at the same time.

= = = = = = = = = = = = = = = = =

2/14/04
During the weekend I discovered some imperfections in what has already been sent to Physics Today. Furthermore, Steven Jones, the only person who knows about my submission (because I asked him to comment on the submitted article, and to criticize it), sent me some comments. Because of this the article was revised and resubmitted today in the traditional way (via post office). Here is the letter I sent today with my printed article:

Department of Mathematical Sciences
Montclair State University
Upper Montclair, NJ, 07055

February 17, 2004

Dr. Stephan G. Benka, Editor-in-Chief
Physics Today, American Institute of Physics
Suite 1NO1, 2 Huntington Quadrangle
Melville, NY, 11747-4502

Dear Dr. Benka:

Last Friday, replying to an e-mail message from Dr. M. Hanna, I at once submitted the electronic version of a paper entitled “Recent cold fusion claims: are they valid?” This paper, I hope, can be published in Physics Today. As I wrote to Dr. Hanna, it is not a paper defending cold fusion claims; it is a paper describing them, no matter what one is inclined to think. Scientifically literate readers are likely to appreciate my short summary of recent claims made by cold fusion researchers. Many physicists are probably not familiar with what has been going on in the area of cold fusion since it was formally evaluated in 1989.

Some of the new cold fusion claims, such as turning Sr into Mo, or Cs into Pr, without stellar temperatures, are even more extraordinary than the claims made by Pons and Fleischmann. The strange thing is that authors of such reports seem to be reputable scientists associated with prestigious universities and laboratories. Is it a matter of fraud? Is it a matter of self-deception, or incompetence? Is it a matter of progressive degeneration due to the isolation of the field from mainstream science? My article does not try to answer these questions; its purpose is to present a summary of what has been recently reported without taking sides. Like many other science teachers, I am in no position to verify validity of hard-to-accept claims in a specialized laboratory. That is why, as suggested in the concluding section, a new evaluation of cold fusion claims, by an appointed panel of experts, is highly desirable. I hope that this suggestion will generate an interesting discussion and comments.

After sending the electronic version of my paper, I discovered a clerical mistake; three references appearing in the text were not listed at the end of the article. And not being sure that subscripts and superscripts would be printed properly by all printers I am sending the paper version of the article with additional minor corrections. Note that references have been renumbered to account for insertions. Please use the paper version of my article instead of the version e-mailed last week. Needless to say, I will be glad to react to suggestions made by your reviewers.

Sincerely yours, Ludwik Kowalski, Ph.D.
Enc.

= = = = = = = = = = = = = = = = =

I still do not know what to think about this episode. What prompted Physics Today to contact me half a year after my letter to the editor was definitively rejected? Will the editor in-chief answer me? What is the chance that my article will be sent to unbiased referees? What is the chance that the reviewers will recommend the acceptance? I have no idea. The second physicist who knows about today's submission (beside Steven Jones) is my Ph.D. thesis adviser, Pierre Radvanyi. He did tell me, when we met in Paris last summer, that Cold Fusion is not worth spending time on. But I could not resist sending him the paper. Will he, whose second specialty is history of nuclear physics, say that I am wasting time? We will see. If the paper is published in Physics Today then one can be reasonably certain that a discussion about the second formal evaluation of cold fusion will develop, in the form of letters to the editor. And who knows, such discussion can lead to some changes of attitude about cold fusion topics. That would be the end of my present mission. After retiring next June I plan to become a cold fusion researcher. The goal will be to look for unexplained charged particles emitted from Steve's Ti foils using track detectors. (like Oriani, Lipson and Karabut).

= = = = = = = = = = = = = = = = = =

3/13/04

I finally received the answer from the editor of Physics Today. " Dear Dr. Kowalski: We received your article submission titled, "Recent Cold Fusion Claims: Are They Valid?," and appreciate your sending it to Physics Today. After reviewing it, however, we have concluded that it does not meet our editorial needs. Thank you for your interest in Physics Today. Sincerely, Stephen G. Benka Editor-in-Chief."

That is it. Not a single word about the content of the article. How can the phrase "does not meet our editorial needs" be interpreted? Why was the article not sent to reviewers? They do publish many field summaries each year. Why was my summary not given the same chance to be reviewed by experts? Was I writing about sociology, poetry, business or something else unconnected to physics? Are recent cold fusion claims described in the article already widely known to most physicists? Was my description of these claims erroneous? Was the article rejected because of its style, its limited scope, or its disregard for ethical standards?

Do I have right, as a member of AAPT, ask for an explanation of the rejection? Is the editor of Physics Today expected to briefly justify his decision to reject a paper? I do not know. Perhaps somebody will provide me with answers to such questions. For the time being I submitted the same paper to American Scientist, by e-mail. Will it be rejected in the same way or will they have the decency to send the article to unbiased reviewers? We will see.

= = = = = = = = = = = = = = = = = =

As indicated above, I might be able to perform cold fusion experiments myself. Suppose the results agree with a claim I am trying to verify? Will they, guardians of the gates, allow me to publish an article describing such results? In another field of science a claim of a discovery, made by a qualified investigator, would be published in a scientific journal. But in the field of cold fusion one should expect a rejection by a mainstream journal. That is what happened after Steven Jones submitted his highly convincing paper to Physical Review. Fortunately that paper is available over the Internet. I would not know about that paper if I hadn't attended the cold fusion conference last fall. Even if the "smoking gun" is found it is difficult to publish the result in a mainstream journal. That is sad; that is discouraging. That is why I would not advise a young researcher to work in the area of cold fusion. The field might die from absence of support and lack of natural continuity.

= = = = = = = = = = = = = = = = = =

DRAFT OF A REPLY (THAT WAS NOT SENT)
Dear Dr. Benka:

I received your message and, naturally, I accept your decision not to publish my paper. I would appreciate, however, some explanation. I spent an entire sabbatical year gathering the material and learning what is summarized in the rejected paper. Please let me know on what basis my paper was rejected. How does it differ from dozens of review papers that our journal publishes each year? Was it a matter of style? Was it a matter of not describing new findings correctly? Was it because I am primarily a physics teacher and not a research scientist? I am not going to argue with you. Please let me know why my manuscript was rejected.

= = = = = = = = = = = = = = = = = =

3/12/04
I am sending the rejected manuscript to another journal -- American Scientist.

3/21/04
Before describing the correspondence with American Scientist let me digress and write about some interesting events. Perhaps these events have something to do with the fact that reviewers' comments (on my Letter to the Editor) were shared with me after six months. Below are extracts from an e-mail message received today.

Eugene Mallove [who died tragically last spring] wrote**:**
1) The U.S. Department of Energy has made a startling reversal of its past refusal to evaluate with a fresh look the large body of experimental evidence that now supports highly anomalous non-chemical magnitude excess heat phenomena in some hydrogen systems, plus associated nuclear anomalies.

2) The confirmation of the DoE review came first in a draft article by Physics Today science journalist Toni Feder. This draft was circulated to several LENR scientists, critics, and others who gave input to Ms. Feder. New Energy Foundation provided input to Ms. Feder and welcomed receipt of the draft article from her. The article is to appear in Physics Today's April 2004 issue, which should be out by the first week of April.

3) The first popular journal to publish the news of the impending DoE review is, however, the UK-based New Scientist. In its March 20, 2004 issue, which was received in the mail today (3/20) at New Energy Foundation here in Concord, New Hampshire, freelance journalist Ben Daviss reports in a short article in the 'Upfront: News in perspective' section (p.6), that James Decker, deputy director of the DoE's Office of Science, 'has pledged to review evidence from the past 15 years of research in the controversial field.' Daviss also writes, 'The study could be completed by January 2005 and might open up the possibility of funding for cold fusion research
projects.' "

If Feder's article is ready to appear in Physics Today then why didn't the editor in chief (Dr. Benka) write to me that an article devoted to the same topic had already been accepted, when he rejected my article nine days ago? Instead he wrote "After reviewing it [your article], however, we have concluded that it does not meet our editorial needs." How can I argue with this? The editor in chief probably has the right to review an article internally instead of sending it to outside experts. An article which has nothing to do with physics could be handled in such way. But my article was devoted to physics only; I deliberately avoided social and historical issues. Somehow I suspect that what Mallowe wrote is not true. On the other hand, why would Eugene put his reputation at stake without being certain? Here's what I found about Toni Feder over the Internet: She is on the Editorial Staff of Physics Today. Was she among those who decided to reject my paper two weeks ago? She is also an Adjunct Assistant Professor at the Department of Physics, Duke University, Ph.D. 1993.

3/23/04
Message sent to an editor of American Scientist (3/23/2004)
Dear Dr. Schoolmaker: Did you receive my manuscript, entitled "Recent cold fusion claims: are they valid?" It was e-

mailed to you on March 12, 2004. I did not expect to be writing this message on the 15th anniversary of the famous cold fusion press release in Utah. That release occurred on March 23, 1989. Shouldn't this be a reason for publishing my review paper? I hope so. But there is another reason as well. According to the last issue of the UK-based New Scientist (March 20, 2004, page 6) the DOE decided to evaluate new research in the area of cold fusion. The text of that announcement is pasted below. This event, if officially confirmed, will naturally renew interest in cold fusion among many readers. Please note that my paper focuses only on scientific aspects of cold fusion. I deliberately avoided references to social aspects, which are interesting but highly controversial. I would be willing to add a paragraph or two devoted to social aspects of cold fusion, if you find this to be desirable. Sincerely yours, Ludwik Kowalski

After waiting more than a week for a confirmation that my submitted paper was received I e-mailed another message to the editor Of American Scientist: In that message I wrote:

. . . Scientifically literate readers are likely to appreciate my short summary of recent claims made by cold fusion researchers. Many readers are probably not familiar with what has been going on in the area of cold fusion since it was formally evaluated in 1989. Some of the new cold fusion claims, such as turning Sr into Mo, or Cs into Pr, without stellar temperatures, are even more extraordinary than the claims made by Pons and Fleischmann. The strange thing is that authors of such reports seem to be reputable scientists associated with prestigious universities and laboratories. Is it a matter of fraud? Is it a matter of self-deception, or incompetence? Is it a matter of progressive degeneration due to the isolation of the field from mainstream science? My article does not try to answer these questions; its purpose is to present a summary of what has been recently reported without taking sides. Like many other science teachers, I am in no position to verify validity of hard-to-accept claims in a specialized laboratory. That is why, as suggested in the concluding section, a new evaluation of cold fusion claims, by an appointed panel of experts, is highly desirable. I hope that this suggestion will generate an interesting discussion and comments. Sincerely yours, Ludwik Kowalski, Ph.D.

= =

3/26/04
After being ignored again I simply called American Scientist and obtained permission to contact the editor in chief Rosalind Reid. I sent her the paper; here is the reply:

Dear Dr. Kowalski:
Yes, we've received your original manuscript and the follow-up. I'm afraid we're not always able to acknowledge receipt immediately. I try to give a prospective author an idea of whether we'll be able to consider a manuscript, and sometimes it takes a little time to determine that. We have certain basic criteria for submissions. When a submission does not meet those criteria, I prefer to say that it cannot be considered rather than simply acknowledge receipt.

In the case of this submission, I'm unsure. We publish feature-length articles and commentaries based on original published research. The authors of American Scientist articles are the people who have done the work and therefore are in a position to survey their own field. I don't actually have evidence (in the form of cited publications or a c.v.) that you have done original research on the topic you propose to write about.

If you would like to publish a short commentary, we do have a department with different criteria, called "Macroscope." This is where we publish short essays conveying a scientist's point of view on a matter of personal or professional interest to scientists and engineers. The maximum word count is 1,500. If you would like us to consider publishing your piece in a short form, please let me know, and I'll share it with my colleagues and let you know the response. Sincerely, Rosalind Reid Editor, American Scientist

Responding to the above I wrote:

Dear Dr. Reid: Thank you for your prompt reply. I understand your hesitation. Protecting readers of American Scientist from people who are not qualified to write about science should be one of your tasks. To help you decide here is a little summary about myself.

I am an experimental nuclear physicist (Ph.D., 1963) with a large number of publications (mostly as coauthor) in that field. The attached abbreviated list of publications, spanning four decades, makes it clear that my teaching commitment has not prevented me from active participation in nuclear physics research. Like most scientists, I accepted the 1989 verdict about cold fusion. And you are correct, I have no publications about cold fusion. My new interest in this field was triggered in October 2002. I attended a nuclear conference in New Mexico and heard several scientists talking about cold fusion research. It was the beginning of my sabbatical year. I changed my anticipated literature research project and focused on cold fusion instead. The paper I submitted is the product of that work.

As you can see, my submitted paper focuses on experimental aspects of nuclear research. I think I am qualified to write about that. Several months ago I got involved in a project headed by Steven Jones. (As you might remember, he was one of the three scientists involved in the famous 1989 controversy.) Our work is in progress and we plan to publish results before the end of this year; most likely at the 12th International Conference on Cold Fusion in Marseilles, France. So I can now say that I am participating in cold fusion research. The goal is to confirm the emission of 3 MeV protons from the activated TiDx foil by using a detector which is very different from that used at BYU. I am sure that Steven Jones will be able to confirm our collaboration. You can contact him at <steven_jones@byu.edu>.

I hope your hesitation will not prevent you from sending my article to competent and unbiased reviewers. Please let me know what your decision will be. Meanwhile I would like to follow your suggestion about writing a short commentary on the anticipated review of cold fusion by the DOE; see the attached file. Thank you for your consideration. Sincerely yours, Ludwik Kowalski

Two files were attached one containing a list of selected publications and another containing the following short note to be considered. I hope that at least this note will be published. Here is its content:

SEEK NOT THE GOLDEN EGG, SEEK THE GOOSE

Ludwik Kowalski
Department of Mathematical Sciences
Montclair State University, Montclair, NJ, 07043

According to a recent article in The New York Times (3/25/2004) the US Department of Energy (DOE) is going to review the field of cold fusion this year. This is a significant event; the controversial field of cold fusion (CF) has often been called pseudoscience. If it were up to me I would suggest that the panel of DOE scientists focus on essential scientific questions and not on practical applications which are far away, at best. Promising too much, and too early, was one of the mistakes made fifteen years ago. In my opinion the six most important scientific questions are:

1) Are unexpected neutrons, protons, tritons and alpha particles emitted (at low rates) in some CF experiments?
2) Is generation of heat, in some CF experiments, linearly correlated with the accumulation of ^{4}He at the rate of 24 MeV per atom of ^{4}He?
3) Have highly unusual isotopic ratios been observed among the elements found in some CF systems?
4) Have radioactive isotopes been produced in some CF systems?
5) Has transmutation of elements occurred in some CF setups?

6) Are the ways of validating scientific findings in the areas of
CF research consistent with accepted methodologies in
other areas of science?

I think that a positive answer to even one of these six questions should be sufficient to justify an official declaration that "cold fusion, in light of recent data, should be treated as a legitimate area of research." The normal peer review mechanisms will then be used to separate valid claims from wishful thinking.

Several hours later I received this reply:
Dear Dr. Kowalski: We'll take a look at the short piece. Meanwhile, I should go just a little further in explaining the requirements for a feature article. Our articles are based entirely on published work; that is, we will be able to consider your feature-article manuscript *after* you've published substantial original research on the topic. Because we do not have our own peer-review process, we must rely on the community to referee original research. An American Scientist review always follows, rather than precedes, journal publication. I wish you the best of luck with your collaboration and hope you'll get back in touch after it has borne fruit. Please give us a couple of weeks to have a look at the short commentary. I'll share the whole package with my colleagues. Sincerely, Rosalind Reid Editor

My answer was:
Dear Dr Reid: Thank you for another prompt reply. I will try to publish the review article in another journal. I suggest that you contact Martin Fleischmann, the central cold fusion figure, or another acceptable author, and ask for a paper about cold fusion. The 15th anniversary, and the pending DOE evaluation of the CF field, justify such initiative, I think. And thank you for giving my short piece a chance of being accepted; the sooner the better. Have a good weekend. Ludwik Kowalski"

TO WHICH JOURNAL SHOULD I SEND MY LONGER PAPER? SHOULD IT BE SCIENTIFIC AMERICAN? WHY NOT? IT IS A DIFFERENT JOURNAL THAN IT USED TO BE IN THE 1960s. BUT I THINK THAT IT IS STILL A VERY APPROPRIATE TARGET FOR MY REVIEW.

3/27/04
ANOTHER MESSAGE TO DR. REID:
After reading our last messages again I see a good reason for sending you another one. In the last sentence you refer to the "whole package." Does it mean that there is a slight possibility that my long paper might still be accepted by American Scientist? Assuming (probably too optimistically) that this is the case I will wait another week before submitting my review paper to another journal. But please, decide sooner, if you can.

You wrote: "Because we do not have our own peer-review process, we must rely on the community to referee original research. An American Scientist review always follows, rather than precedes, journal publication." I respect that policy and think it is good. But what about review papers? It is not likely that you can find an author who actually worked in all fields of a broad area to be reviewed. The so-called "cold fusion" is an area of many different fields and, as far as I know, nobody worked in more than one of them. Each area is highly specialized in terms of expertise and instruments. The authors, as I found out, often disagree with each other and the only thing that unites them is rejection by "mainstream science." My paper, as you know, is a review of that controversial field.

I already mentioned two reasons making such review urgent: the 15th anniversary of the Utah announcement and the pending DOE investigation. In my opinion, by publishing my paper, or a review written by somebody else, you will contribute to something desirable. Nobody is happy with the unhealthy feud between a group of well motivated researchers and official representatives of "mainstream science." Most people are passive but those who do take extreme positions often use highly pejorative adjectives, such as "pathological", " stubborn, " misguided," and "fraudulent." Please do not miss an opportunity to contribute to ending this unnecessary feud. I would be happy to give you names and addresses of top people in five main areas of cold fusion.

Yesterday I wrote to you about my current cooperation with Steven Jones from BYU in Utah. But I forgot to mention another cold fusion project in which I participated during the 2002/2003 sabbatical year. I will not mention the name of

the man who accepted my suggestion to repeat his experiment together. The outcome was not positive. His very extravagant claim was not confirmed through experiments that we performed together. But it was not a case of fraud, it was a case of limited experience in a complex area. The reaction of that highly committed man was to recognize experimental data. A con artist would never allow an outsider to examine his "bag of tricks."

So now you have several excuses for bending a rule of your editorial policy. They are: a) the anniversary, b) the pending DOE investigation, c) my paper is a review describing (very objectively, and without accusations of any kind, as you probably noticed) several very different areas of a broad field, d) my background as an active nuclear physicist, and e) my unpublished research in two areas of cold fusion. You are certainly aware how difficult it is to publish cold fusion research papers in important scientific journals. Will the situation change after the pending DOE investigation of cold fusion? I hope so. Please help to contribute to this cause.

If you decide to approach Fleischmann, be aware that he is an electrochemist; I do not consider him to be an expert in nuclear physics. This became clear in 1989 and contributed heavily to the cold fusion controversy. One can only imagine what would happen if Fleischmann and Pons, who are chemists, refused to participate in the infamous press release, organized by the administrators of the University of Utah, and decided to work with Steven Jones, who is a physicist. A year or two later they would publish a peer reviewed paper and . . . But I refuse to speculate; my goal is heal the wound by focusing on purely scientific topics and by ignoring stupid things people said or wrote before. Please help me. I think that cold fusion, no matter what the final verdict will be, is a highly significant episode in the history of science. Let your journal be a part of that history.

P.S. (dated 3/28/04)
Do you want an author with a much better record of publishing cold-fusion-related papers than me? If so then let me make some suggestions. I already mentioned Martin Fleischmann. Here are some other names:

1) George Miley, University of Illinois
g-miley@uiuc.edu

2) Peter Hagelstein, MIT
phagelstein@aol.com

3) Edmund Storms, retired from LANL
storms2@ix.netcom.com

4) John Dash, Portland State University
dashj@pdx.edu

5) Steven Jones, Brighman Young University.
steven_jones@byu.edu

Actually Jones should be on top of this list because he was probably the first to use the term "cold fusion." This was in the title of his 1987 article in Scientific American; he was working under the DOE grant at that time.

As you know, I am now working on Jones' project and he corrected two serious mistakes in the draft of the paper I want to publish. Would you publish this paper if I convinced Jones to become a coauthor? If so I would be glad to ask him. Please be aware that, except Jones, none of the above knows about my initiative. But I know these people and you can say that the name was suggested by me. Best regards again, Ludwik Kowalski

3/29/04
REPLY FROM Dr. REID:
Dear Dr. Kowalski: By saying I'd share "the whole package," I meant that your longer manuscript (and the information you've provided in your messages) will provide good background for my colleagues in considering your proposal for a short essay. Thank you for the list of prospective authors provided in your "post scriptum." We'll consider that separately. Rosalind Reid

[Today is 6/28/04. I never heard from American Scientist again. Will they tell me about their decision to publish or not publish the short piece? I do not think so.]

= = = = = = = = = = = = = = = = = = =

3/31/04 (Submitting paper to Scientific American):
Dear Dr. Rennie: I am sure that you are aware of the DOE move to review the cold fusion field, as reported in The New York Times (3/25/04). Attached is a review article which, I hope, can be published in Scientific American. The title is "Recent cold fusion claims: are they valid?" It is not a paper defending cold fusion claims; it is a paper describing them, no matter what one is inclined to think. Scientifically literate readers are likely to appreciate my short summary of recent claims made by cold fusion researchers.

Some of these claims, such as turning Sr into Mo, or Cs into Pr, without stellar temperatures, are even more extraordinary than the claims made by Pons and Fleischmann. The strange thing is that authors of such reports seem to be reputable scientists associated with prestigious universities and laboratories. Is it a matter of fraud? Is it a matter of self-deception, or incompetence? Is it a matter of progressive degeneration due to the isolation of the field from mainstream science? My article does not try to answer these questions; its purpose is to present a summary of what has been recently reported without taking sides. The subject is interesting no matter what the final verdict of the second DOE evaluation will be.

Like many other science teachers, I am in no position to verify validity of hard-to-accept claims in a specialized laboratory. That is why, as suggested in the concluding section, a new evaluation of cold fusion claims, by an appointed panel of experts, is highly desirable. In writing this I was not aware of the pending DOE investigation.

I deliberately avoided references to social aspects, which are interesting but highly controversial. I am a physics teacher at Montclair State University. Studying cold fusion was my 2003/2004 sabbatical project, which resulted in the attached manuscript Sincerely yours, Ludwik Kowalski, Ph.D. Professor of Physics, Montclair State University, Montclair, NJ

[The answer came much later than I expected (6/14/04). here it is:]

Dr. Kowalski: Thank you for your offer to contribute to SCIENTIFIC AMERICAN. After much consideration, I regret to say that the piece you propose is not suited to our somewhat limited editorial needs. We appreciate your interest in SCIENTIFIC AMERICAN. Regards, Jacob Lasky Editorial Administrator. Did Dr Rennie, to whom my first message was addressed, retire?]

After giving up on Scientific American and tried to publish my paper in Nature. Instead of sending the article to them I decided to follow the presubmission path. The most impressive part of the path was that the negative reply came about ten hours later. The process of presubmission consists of filling two text boxes on their web site. The first box was for the letter about my article; I wrote essentially the same as what I wrote to the editor of Scientific American (see above). The second box was for the first paragraph of my paper, and for the references used in it. I wrote:

"Cold fusion (CF), presumably discovered 15 years ago, is any process in which a nuclear reaction is produced without relying on traditional means, such as particle accelerators, neutron sources or stellar temperatures. In 1989, several months after the discovery was announced (through a press release at the University of Utah) a panel of scientists, appointed by the US Department of Energy (DOE), examined the evidence supporting the CF claims. That evidence was declared insufficient. But, as summarized in (1) 'there remain unresolved issues which may have interesting implications. The Panel is, therefore, sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system.'

CF became highly controversial and only several hundred researchers continued working on it, world-wide. Most scientists still think that cold fusion is pseudoscience. On that basis editors of many journals refuse to publish papers

devoted to CF research. Only a small fraction of scientists is familiar with recent progress in that area. The purpose of this article is to objectively summarize recent findings (2) and to supply references with which I am familiar. The article was triggered by the reported initiative of DOE to review (3,4) cold fusion research. I will focus on four cold fusion claims which are, in my opinion, the most important. As a nuclear physicist, and a physics teacher, I examined some of CF publications and attended one cold fusion conference (5).

1. Huizenga, J. *Cold Fusion: the Scientific Fiasco of the Century*. Oxford University Press, 2nd edition, Oxford, 1993.
2. Cold fusion papers are usually published at specialized scientific conferences. Many of them are downloadable from the library at http://www.lenr-canr.org.
3. Daviss, B. "No Cold Shoulder." *New Scientist*, March 20, 2004, p 6.
4. Feder, T. "DOE Warms to Cold Fusion," *Physics Today*, April 2004, page 27.
5. The Tenth International Conference on Cold Fusion was held in Cambridge, Massachusetts 24 - 29 August 2003. Conference proceedings, in the form of Pdf files, can be downloaded from http://www.lenr-canr.org/iccf10/iccf10.htm "

The reply was short and clear;
"Thank you for your inquiry about submitting your paper entitled 'Cold fusion 15 years later' to Nature. I regret that the paper that you describe seems unlikely to prove suitable for publication in Nature, and we accordingly suggest that you pursue publication elsewhere. I am sorry that we cannot respond more positively on this occasion. Yours sincerely Dr Karen Southwell, Senior Editor." I was aware, from browsing their web site, that the rate of acceptance in Nature is about 1 out of 10. On that basis I should have expected a rejection.

Corresponding with Brian D. Josephson [a Nobel laureate]
Cavendish Lab, Cambridge CB3 0HE, U.K.
Dear Dr. Brian Josephson
I am one of many to whom the Physics Today article (about cold fusion) was distributed today by Eugene Mallove. At first I thought it was an April Fool's joke. Seeing your name on the list of e-mail destinations reminded me that you wrote about negative aspects of the cold fusion situation in the past. May I suggest that you write a Letter to the Editor of Physics Today with comments on the upcoming DOE evaluation. Considering your reputation that letter may become important. Please write what, in your opinion, the task of a new panel should be.

And here is his reply:
Dear Ludwik, Thanks for your e-mail. Steve Krevit and Nadine Winocur, editors of New Energy Times, have sent in a very good letter to PT, and I don't think there's very much worth adding to the combination of that and the original article, so probably I should leave it at that. But it was a good idea of yours! Actually New Scientist reported the situation last week (i.e. in March!), and those in the know had heard about the PT article before then. Brian J.

In a subsequent message Josephson added: ". . . Nothing's impossible in this domain -- Nature often does not publish letters from me. Anyway, I've sent in an endorsement of the other letter which I mentioned." Hmm, a paper from a Nobel laureate being rejected? This is hard to believe.

4/2/04
Letter to The Editor of Physics Today. (Responding to Ferder's article that was sent to me over the internet by Mallowe):

Dear Dr. Hanna: Assuming the Toni Feder's article distributed yesterday over the Internet was not an April Fool's joke,

I am sending you my reaction to it. Please publish it as a Letter to the Editor of Physics Today. Respectfully yours, Ludwik Kowalski

Here is the content my letter:

Cold fusion; science or pseudoscience?
I agree with Toni Feder (Physics Today, April 2004, page 27) that "skepticism about the credibility and reproducibility of cold fusion remains widespread." As a physics teacher who is not certain how students' questions about cold fusion should be answered, I welcome the upcoming DOE investigation of recent claims in this controversial area. Here are questions which I would like to see answered by the appointed investigators: **a)** Is it true that unexpected emission of neutrons, protons, tritons and alpha particles (at low rate) has been observed in several cold fusion experiments? **b)** Is it true that accumulation of ^{4}He, at the rate of about one atom per 24 MeV of excess heat, has been confirmed by many scientists, as reported by McKubre? **c)** Is it true that highly abnormal isotopic ratios have been found in some cold fusion setups? **d)** Is there any indication that leading cold fusion scientists are incompetent in the areas they investigate? **e)** Is there any indication that their data are fraudulent? **f)** Is the research methodology used by them different from the methodology used in other areas of physical science?

Answers to these questions will help me decide what to think about cold fusion and what to tell students about it. Speculations about practical applications of new findings, in my opinion, should be de-emphasized at this time. They will emerge naturally when basic scientific claims are recognized as valid, and when cold fusion researchers are no longer treated as if they were con artists and charlatans. The "chilling effect," mentioned by Randall Heckman, prevents young scientists from entering the area of cold fusion research. I agree with Allen Bard that being able to reproduce experimental results is not "good enough;" it is only a prelimanary step. But is it not true that poor reproducibility was the central point of criticism when cold fusion was first investigated fifteen years ago?

4/12/04
The editor wrote:
Dear Dr. Kowalski: Your letter has not yet gone to reviewers. There are quite a few in the queue ahead of it, and my reviewers are staff editors who are all busy in current assignments to get Physics Today's May issue out the door. I'll be happy to include your definition of cold fusion in the folder with your letter as it travels through the review process. That process should begin later this week. Thank you for your patience. Kind regards, Marty Hanna Letters Editor, Physics Today.

My immediate reply was:

Dear Dr. Hanna: Thank you for giving my letter to the editor a chance. I also hope that Feder's article will result in a lively discussion. If I had to write my letter again I would insert the opening sentence: "Cold fusion is any process in which a nuclear reaction is produced without relying on traditional means, such as particle accelerators, neutrons, cosmic rays, alpha particles or stellar temperatures." It is probably too late to introduce this change; I do not want to delay the letter.

Feel free to use my definition in any way you wish. I think that either you, or Tony Feder, should define cold fusion before the discussion begins. Unfortunately the term "cold fusion" means different things to different people. It is certainly premature to define cold fusion as a practically unlimited energy resource. But that is what most people say when asked to describe CF. I suspect that many disagreements about CF would disappear if its definition were accepted by all antagonists.

= = = = = = = = = = = = = = = = = = =

4/17/04
Frustrated that my timely review of the Cold Fusion field is being delayed I decided to send it to another UK journal, New Scientist. I wrote:

Dear Editors: I have a 3048 word article entitled "Cold fusion 15 years later" which has just been rejected by a research-oriented journal. I would be happy to rewrite it (preferably with one of your science journalists as coauthor) for your readers. Below are three short descriptions of it: one for the general public; one for scientists; and one showing what I wrote to editors of the journal that rejected my review. I would be glad to e-mail you the article if you are interested.

Let me add that I am a physics professor and a researcher with many nuclear science publications. The paper I wrote is a summary of my 2002/2003 sabbatical project. I attended the 2003 International Cold Fusion Conference and have two photos which may be worth adding. Both Martin Fleischmann and Steven Jones (whose CF research triggered the 1989 controversy) gave me signed permission to publish the photos.

Description for general readers
Cold fusion (CF) has been a highly controversial area in science due to: the way in which the discovery was initially announced (via a press release in 1989), difficulties reproducing critical CF experiments, and the highly unusual nature of CF claims. The article describes four such claims and provides references for additional learning. The US Department of Energy (DOE) will soon review the CF field. Are CF claims valid? If they are then practical applications might be developed on the basis of new discoveries. The article focuses on basic science and not on potential applications.

Description for scientists
Cold fusion is defined as "any process in which a nuclear reaction is produced without relying on traditional means, such as particle accelerators, neutron sources, stellar temperatures, cosmic rays or alpha particles. " This article is a review of recent papers describes four cold fusion processes: a) emission of nuclear particles, such as neutrons and protons, b) generation of excess heat of nuclear origin, c) accumulation of reaction products with highly unusual isotopic ratios, and d) nuclear transmutation of elements. The purpose is to explain cold fusion and to provide references. The article was prompted by the pending review of the field in the US.

Description for editors
I am sure that you are aware of the DOE move to review the cold fusion field. This event prompted me to submit a review article which, I hope, can be published. It is not an article defending cold fusion claims; it is an article describing the most important cold fusion reports objectively. Some of the claims, such as turning Sr into Mo, or Cs into Pr, without stellar temperatures, are even more extraordinary than the 1989 claims made by Pons and Fleischmann. The strange thing is that authors of described reports seem to be reputable scientists associated with prestigious universities and laboratories. Is it a matter of fraud? Is it a matter of self-deception, or incompetence? Is it a matter of progressive degeneration due to the isolation of the field from mainstream science? My article, containing 37 references, does not try to answer these questions; its purpose is to present a summary of what has been reported in the last ten years, without taking sides. The subject is interesting no matter what the final verdict of the second DOE review will be.

5/3/04
Neither Scientific American nor New Scientist confirmed that my submitted paper was received. I have no indication from Physics Today that my letter to the editor will be published. Should I ask for the confirmation of this? No, I will wait another two or three weeks. Also no words from American Scientist (about the Golden Egg piece that they said will be considered). Facing this situation I submitted the article (slightly modified) to The Physics Teacher today. Here was the letter to Dr. Mamola to which the manuscript was attached.

Dear Dr. Mamola: As you probably remember, the manuscript on Cold Fusion that I submitted about two years ago was rejected by your reviewers. My letter to the editor, however, was published last summer. I was pleased by this. The topic, as you know (see the "DOE WARMS to Cold Fusion" article in last April issue of Physics Today), is likely to be of great interest in the near future. With this in mind I wrote a **new article** on Cold Fusion and I hope that you will be able to publish it next fall. As you will see, I am simply describing controversial claims, I am not defending them. An extensive list of references is provided for those teachers who might wish to familiarize themselves with recent papers. The length is 3302 words, including 37 references. If necessary I can shorten the article, and reduce the list of references. But I prefer not to do this because I believe that everything is important.

I think I already wrote to you that my renewed interested in Cold Fusion was triggered by an accidental encounter, and

that my 2001/2003 sabbatical year was devoted to literature research in that field. I am still undecided about validity of cold fusion claims but I think that they should be known to physics teachers. Unfortunately, most of them are, as I was before September 2001, not familiar with experimental data gathered in the last ten years. The pending evaluation of the field by the DOE is likely to be publicized in the media and lead to student interest and questions. Hopefully, my paper will help teachers deal with the renewed interest in the "forbidden field." The manuscript, in MS Word format, is attached.

The following confirmation from the journal arrived in less than two hours.

The Physics Teacher magazine acknowledges receipt of your manuscript "Cold Fusion 15 Years Later" on 5/3/04. Your manuscript has been assigned the number: 420502. Our editorial office will appreciate it if you refer to this number in any future correspondence regarding the submission. After the editor has reviewed your manuscript, we will contact you with his comments and/or recommendation. Thank you for your interest in TPT.

6/ 9/04
More that a month later I received the following rejection: "Dear Professor Kowalski: We have reviewed your manuscript "Cold Fusion 15 Years Later" in the light of the recent Physics Today article "DOE Warms to Cold Fusion." While a paper in TPT on this subject may be warranted, we do not believe there is any great urgency to publish one immediately. After all, according to the Physics Today piece, DOE Deputy Director Decker says that their "review of cold fusion will begin in the next month or so [that was back in April]" and it "won't take a long time –- it's a matter of weeks or months." We believe that it would be premature to publish a cold fusion paper in TPT before the results of the DOE review are announced. Were we to do so, a follow-up piece would almost certainly be required later, regardless of how that review turns out, and we don't feel that two papers on the subject are warranted. We will consider your paper again (along with any revisions induced by the DOE report) after the report is made public."

My immediate reply was: "Dear Dr. Mamola: Was my manuscript examined by referees? I would very much like to see what they had to say about its content. Thanks in advance."

6/28/04
I am still waiting for referee's comments. What should I do? I will wait a little longer and then post the review article as item #152 on my web site. How many people will read it? i do not know. I will also turn this summary into a poster for the next Cold Fusion Conference. The fight for a better climate in the area of Cold Fusion is going to continue. Will the pending DOE review end the unhealthy feud about cold fusion? Will it result in elimination of administrative barriers (such as rejection of articles without the peer review process)? What motivates defenders of the status quo? Who benefits from it? Yes these questions belong to the realm of social sciences. But that does not mean they should remain unanswered.

154) History of attempts to publish a paper

Ludwik Kowalski (6/29/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

My 2004 paper, reviewing recent cold fusion claim, has been rejected (without sending it to referees and without offering any criticism) by editors of six journals:

1) Physics Today, USA
2) American Scientist, USA
3) Scientific American, USA
4) Nature, UK
5 New Scientist, UK
6) The Physics Teacher, USA
7) Science, USA

This poster traces histories of rejections. The paper itself can be seen as items #152 at my web site Montclair State University:

http://csam.montclair.edu/~kowalski/cf/

- -

1) February 12, 2004
Here is how my paper was introduced to the editor of one of the above journals. Other accompanied letters were similar.

I am sure that you are aware of the DOE move to review the cold fusion field, as reported in The New York Times (3/25/04). Attached is a review article which, I hope, can be published in Scientific American. The title is "Recent cold fusion claims: are they valid?" It is not a paper defending cold fusion claims; it is a paper describing them, no matter what one is inclined to think. Scientifically literate readers are likely to appreciate my short summary of recent claims made by cold fusion researchers.

Some of these claims, such as turning Sr into Mo, or Cs into Pr, without stellar temperatures, are even more extraordinary than the claims made by Pons and Fleischmann. The strange thing is that authors of such reports seem to be reputable scientists associated with prestigious universities and laboratories. Is it a matter of fraud? Is it a matter of self-deception, or incompetence? Is it a matter of progressive degeneration due to the isolation of the field from mainstream science? My article does not try to answer these questions; its purpose is to present a summary of what has been recently reported without taking sides. The subject is interesting no matter what the final verdict of the second DOE evaluation will be.

Like many other science teachers, I am in no position to verify validity of hard-to-accept claims in a specialized laboratory. That is why, as suggested in the concluding section, a new evaluation of cold fusion claims, by an appointed panel of experts, is highly desirable. In writing this I was not aware of the pending DOE investigation. I deliberately avoided references to social aspects, which are interesting but highly controversial. I am a physics teacher at Montclair State University. Studying cold fusion was my 2003/2004 sabbatical project, which resulted in the attached manuscript

In rejecting my paper the editor of **Physics Today** wrote: " Dear Dr. Kowalski: We received your article submission titled, "Recent Cold Fusion Claims: Are They Valid?," and appreciate your sending it to Physics Today. After reviewing

it, however, we have concluded that it does not meet our editorial needs. Thank you for your interest in Physics Today. Sincerely, Stephen G. Benka Editor-in-Chief."

That is it. Not a single word about the content of the article. How can the phrase "does not meet our editorial needs" be interpreted? Why was the article not sent to referees? They do publish many field summaries each year. Why was my summary not given the same chance to be reviewed by experts? Was I writing about sociology, poetry, business or something else unconnected to physics? Are recent cold fusion claims described in the article already widely known to most physicists? Was my description of these claims erroneous? Was the article rejected because of its style, its limited scope, or its disregard for ethical standards?

And here how the editor of **American Scientist** responded to my submission:
Dear Dr. Kowalski: Yes, we've received your original manuscript and the follow-up. I'm afraid we're not always able to acknowledge receipt immediately. I try to give a prospective author an idea of whether we'll be able to consider a manuscript, and sometimes it takes a little time to determine that. We have certain basic criteria for submissions. When a submission does not meet those criteria, I prefer to say that it cannot be considered rather than simply acknowledge receipt.

In the case of this submission, I'm unsure. We publish feature-length articles and commentaries based on original published research. The authors of American Scientist articles are the people who have done the work and therefore are in a position to survey their own field. I don't actually have evidence (in the form of cited publications or a c.v.) that you have done original research on the topic you propose to write about.

If you would like to publish a short commentary, we do have a department with different criteria, called "Macroscope." This is where we publish short essays conveying a scientist's point of view on a matter of personal or professional interest to scientists and engineers. The maximum word count is 1,500. If you would like us to consider publishing your piece in a short form, please let me know, and I'll share it with my colleagues and let you know the response. Sincerely, Rosalind Reid Editor, American Scientist

Responding to the above I wrote:
Dear Dr. Reid: Thank you for your prompt reply. I understand your hesitation. Protecting readers of American Scientist from people who are not qualified to write about science should be one of your tasks. To help you decide here is a little summary about myself.

I am an experimental nuclear physicist (Ph.D., 1963) with a large number of publications (mostly as coauthor) in that field. The attached abbreviated list of publications, spanning four decades, makes it clear that my teaching commitment has not prevented me from active participation in nuclear physics research. Like most scientists, I accepted the 1989 verdict about cold fusion. And you are correct, I have no publications about cold fusion. My new interest in this field was triggered in October 2002. I attended a nuclear conference in New Mexico and heard several scientists talking about cold fusion research. It was the beginning of my sabbatical year. The paper I submitted is the product of that work.

I hope your hesitation will not prevent you from sending my article to competent and unbiased reviewers. Please let me know what your decision will be. Meanwhile I would like to follow your suggestion about writing a short commentary on the anticipated review of cold fusion by the DOE; see the attached file. Thank you for your consideration. Sincerely yours, Ludwik Kowalski"

A list of my selected publications, and a file containing my "short piece" (see below), were attached.

SEEK NOT THE GOLDEN EGG, SEEK THE GOOSE

According to a recent article in The New York Times (3/25/2004) the US Department of Energy (DOE) is going to review the field of cold fusion this year. This is a significant event; the controversial field of cold fusion (CF) has often

been called pseudoscience. If it were up to me I would suggest that the panel of DOE scientists focus on essential scientific questions and not on practical applications which are far away, at best. Promising too much, and too early, was one of the mistakes made fifteen years ago. In my opinion the six most important scientific questions are:

1) Are unexpected neutrons, protons, tritons and alpha particles emitted (at low rates) in some CF experiments?
2) Is generation of heat, in some CF experiments, linearly correlated with the accumulation of ^{4}He at the rate of 24 MeV per atom of ^{4}He?
3) Have highly unusual isotopic ratios been observed among the elements found in some CF systems?
4) Have radioactive isotopes been produced in some CF systems?
5) Has transmutation of elements occurred in some CF setups?
6) Are the ways of validating scientific findings in the areas of CF research consistent with accepted methodologies in other areas of science?

I think that a positive answer to even one of these six questions should be sufficient to justify an official declaration that "cold fusion, in light of recent data, should be treated as a legitimate area of research." The normal peer review mechanisms will then be used to separate valid claims from wishful thinking.

In a subsequent reply I wrote: " ... I already mentioned two reasons making such review urgent: the 15th anniversary of the Utah announcement and the pending DOE investigation. In my opinion, by publishing my paper, or a review written by somebody else, you will contribute to something desirable. Nobody is happy with the unhealthy feud between a group of well motivated researchers and official representatives of "mainstream science." Most people are passive but those who do take extreme positions often use highly pejorative adjectives, such as "pathological", " stubborn, " misguided," and "fraudulent." Please do not miss an opportunity to contribute to ending this unnecessary feud. I would be happy to give you names and addresses of top people in five main areas of cold fusion. . . .

So now you have several excuses for bending a rule of your editorial policy. They are: a) the anniversary, b) the pending DOE investigation, c) my paper is a review describing (very objectively, and without accusations of any kind, as you probably noticed) several very different areas of a broad field, d) my background as an active nuclear physicist, and e) my unpublished research in two areas of cold fusion. You are certainly aware how difficult it is to publish cold fusion research papers in important scientific journals. Will the situation change after the pending DOE investigation of cold fusion? I hope so. Please help to contribute to this cause.

If you decide to approach Fleischmann, be aware that he is an electrochemist; I do not consider him to be an expert in nuclear physics. This became clear in 1989 and contributed heavily to the cold fusion controversy. One can only imagine what would happen if Fleischmann and Pons, who are chemists, refused to participate in the infamous press release, organized by the administrators of the University of Utah, and decided to work with Steven Jones, who is a physicist. A year or two later they would publish a peer reviewed paper and ..... But I refuse to speculate; my goal is heal the wound by focusing on purely scientific topics and by ignoring stupid things people said or wrote before. Please help me. I think that cold fusion, no matter what the final verdict will be, is a highly significant episode in the history of science. Let your journal be a part of that history. . .

I also gave Dr. Reid names and e-mail addresses of five people (who are certainly much more knowledgeable than myself) suggested that she contacts one of them to write a longer review paper of the journal. Steven Jones, Martin Fleicshmann and George Miley were among the scientists I selected. I did not hear never from Dr. Reid again. Will she accept my "short piece?" Probably not. The "long piece" was submitted to **Scientific American.** Here is the reply that came after a long delay:

"Dr. Kowalski: Thank you for your offer to contribute to SCIENTIFIC AMERICAN. After much consideration, I regret to say that the piece you propose is not suited to our somewhat limited editorial needs. We appreciate your interest in SCIENTIFIC AMERICAN. Regards, Jacob Lasky Editorial Administrator."

After giving up on Scientific American and tried to publish my paper in **Nature**. Instead of sending the article to them I decided to follow the presubmission path. The most impressive part of the path was that the negative reply came about ten hours later. The process of presubmission consists of filling two text boxes on their web site. The first box was for the letter about my article; I wrote essentially the same as what I wrote to other editors. The second box was for the first paragraph of my paper, and for the references used in it. The reply was short and clear:

"Thank you for your inquiry about submitting your paper entitled 'Cold fusion 15 years later' to Nature. I regret that the paper that you describe seems unlikely to prove suitable for publication in Nature, and we accordingly suggest that you pursue publication elsewhere. I am sorry that we cannot respond more positively on this occasion. Yours sincerely Dr Karen Southwell, Senior Editor."

I was aware, from browsing their web site, that the rate of acceptance in Nature is about 1 out of 10. On that basis I should have expected a rejection. Frustrated that my timely review of the Cold Fusion field is being delayed I decided to send it to another UK journal, **New Scientist**. But they never responded. After waiting about a month the article was submitted to **The Physics Teacher**, a journal in which several of my teacher-oriented review papers were published in the past. In submitting the article I wrote:

Dear Dr. Mamola: As you probably remember, the manuscript on Cold Fusion that I submitted about two years ago was rejected by your reviewers. My letter to the editor, however, was published last summer. I was pleased by this. The topic, as you know (see the "DOE WARMS to Cold Fusion" article in last April issue of Physics Today), is likely to be of great interest in the near future. With this in mind I wrote a **new article** on Cold Fusion and I hope that you will be able to publish it next fall. As you will see, I am simply describing controversial claims, I am not defending them. An extensive list of references is provided for those teachers who might wish to familiarize themselves with recent papers. The length is 3302 words, including 37 references. If necessary I can shorten the article, and reduce the list of references. But I prefer not to do this because I believe that everything is important.

. . . I am still undecided about validity of cold fusion claims but I think that they should be known to physics teachers. Unfortunately, most of them are not familiar with experimental data gathered in the last ten years. The pending evaluation of the field by the DOE is likely to be publicized in the media; this will lead to student interest and questions. Hopefully, my paper will help teachers deal with the renewed interest in the "forbidden field."

More that a month later I received the following rejection:
"Dear Professor Kowalski: We have reviewed your manuscript "Cold Fusion 15 Years Later" in the light of the recent Physics Today article "DOE Warms to Cold Fusion." While a paper in TPT on this subject may be warranted, we do not believe there is any great urgency to publish one immediately. After all, according to the Physics Today piece, DOE Deputy Director Decker says that their "review of cold fusion will begin in the next month or so [that was back in April]" and it "won't take a long time –- it's a matter of weeks or months." We believe that it would be premature to publish a cold fusion paper in TPT before the results of the DOE review are announced. Were we to do so, a follow-up piece would almost certainly be required later, regardless of how that review turns out, and we don't feel that two papers on the subject are warranted. We will consider your paper again (along with any revisions induced by the DOE report) after the report is made public."

My immediate reply was: "Dear Dr. Mamola: Was my manuscript examined by referees? I would very much like to see what they had to say about its content. Thanks in advance." This message has not yet been answered. Will I see the referee's comments? Probably not.

Will the pending DOE review end the unhealthy feud about cold fusion? Will it result in elimination of administrative barriers (such as rejection of articles without the peer review process)? What motivates defenders of the status quo? Who benefits from it? Yes these questions belong to the realm of social sciences. But that does not mean they should remain unanswered.

This afternoon the review manuscript was submitted to the Editor in Chief of **Science**, Donald Kennedy. Here is the reply received next day, Staurday afternoon: " I've consulted with our editorial staff in the physical sciences. Unfortunately, we don't think this topic is an appropriate one for review in Science at this time. Thanks for thinking of Science. Sincerely yours. Donald Kennedy." Hmm, very efficient; they had only couple of hours on Friday to read the manuscript. It was rejected because the topic is not appropriate. Why is it not appropriate? Aren't the described claims scientific?

A more detailed description of correspondence with the editors can be found in item #153 on my website dedicated to cold fusion:

http://csam.montclair.edu/~kowalski/cf/

P.S. Novenber 30, 2004 (One day before the DOE report was released)

Dear Dr. Mamola:

As you might recall (see the message quoted below) I wanted to publish a paper "Cold Fusion 15 Years Later," several months ago. A that time I was essentially an uncommitted observer of the field. My review paper is still waiting to be modified after the DOE panel report, as you suggested. The purpose of this message is to inform you that I have recently replicated two "cold fusion" experiments of Dr. Oriani, at the University of Minnesota. The label "cold fusion" is not appropriate here because neither heavy water nor palladium were used in the setup. And we do not believe that two isolated atomic nuclei could fuse at a low temperature to produce an observable effect. The probability of fusion, due to the tunneling effect, is too small for this. The only link between the concept of "cold fusion" and what we observed is a totally unexpected nuclear effect caused by chemical activity in an experimental setup. The Oriani effect was replicated by me twice (out of two attempt), as described at:

http://csam.montclair.edu/~kowalski/cf/188oriani.html

I know that most nuclear physicists are convinced that chemical processes cannot produce nuclear effects. But I also believe that experiments have priority in Physics. A task of trying to prove, or disprove, a controversial claim, made by a reputable scientist (such as Dr. Richard Oriani), can be turned into an educational project. What can be a better way to expose students to the excitement of scientific research? Please let me know if we should submit a paper, based on the above webpage, for a possible publication in The Physics Teacher. I am now trying to get ready for one more experiment, with a totally new cell, with new chemicals and at our university laboratory. The article will be submitted if the number of tracks is again much larger than the background.

The purpose would be to inform teachers about Oriani effects, and to encourage them to test one of them. Many high schools and universities are equipped to perform the simple experiment described in my webpage. Hopefully, some of them will attempt to replicate it. Please reply as soon as possible; we hope you will give our paper a chance of being published in TPT. The cold fusion, and the controversy about it, will not even be mentioned in our draft.
Sincerely yours,
Ludwik Kowalski

> Dear Professor Kowalski:
> We have reviewed your manuscript "Cold Fusion 15 Years Later" in the
> light of the recent /Physics Today /article "DOE Warms to Cold Fusion."
> While a paper in /TPT/ on this subject may be warranted, we do not
> believe there is any great urgency to publish one immediately. After all, . .
The rest of this message can be seen above.

P.S. December 13, 2004

Dear Professor Kowalski:

Our editorial staff has examined the discussion given at the URL provided in your message. While the materials required to conduct the Oriani (c) experiment might be accessible to schools, we believe that too few of our readers would consider the exercise to be appropriate for inclusion in their introductory-level physics courses. Because of space constraints, we are now able to publish fewer than one-third of the submissions we receive. We must therefore take care to select those which we believe would be of the greatest benefit to our readers. While we would be willing to review a completed manuscript of the sort you describe, we are not optimistic that it would be accepted for publication.

Sincerely, Karl C. Mamola
Editor

155) A VERY GOOD ARTICLE OF EDMUND STORMS

Ludwik Kowalski (7/1/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

What follows is an excellent article; it should be read by those who are interested in excess power resulting from the so-called "cold fusion." The author, who I met at the 10th International Cold Fusion Conference (August 2003), is an authority in the area of excess heat. He uses the acronym LENR (low energy nuclear reactions) wher many usethe trem "cold fusion." The pdf file containing the article (with figures which I do not show) can be downloaded from:

http://www.lenr-canr.org

As in unit #148, I inserted many questions (capital letters in red) into Storms' paper. The purpose, as before, is to show things that were not obvious to me. Note that some of the questions asked in unit #148 were unexpectedly answered, by Richard Eskimos, in unit #150. Perhaps somebody will answer questions formulated in this unit. I also inserted some comments.

Calorimetry 101 for Cold Fusion; Methods, Problems and Errors

Edmund Storms
Energy K. Systems
Santa Fe, NM

(1***) WHY THERE IS NO DATE? (THE ACKNOWLEDGEMENT SHOWS 2003)

ABSTRACT
Application of calorimetry to cold fusion or LENR presents unique problems that have not been previously summarized. This paper discusses various calorimetric methods that have been applied to the subject and evaluates each in light of what has been discovered about their limitations and errors based on experimental studies. Such information is essential to a study of the effect and to evaluate the results.

I. INTRODUCTION

LENR (Low Energy Nuclear Reactions) is a new mechanism for initiating nuclear reactions within special solid materials without application of energy normally required to overcome the Coulomb barrier. When the mechanism is applied to the D-D fusion reaction, the better known term "Cold Fusion" is used. These reactions produce three kinds of evidence: electromagnetic radiation, nuclear products, and heat. The radiation is generally weak and most is absorbed before it can reach the detector. Nuclear products can be detected, but analysis is difficult because the products occur in such small amounts. Finally, the abnormally large amount of heat energy that is generated can be measured. This

technique requires use of calorimetry, as described here.

Calorimetry is the measurement of heat energy. Although this is an old science that underpins much of thermodynamics and modern chemistry, when such measure-ments are applied to LENR, several unique problems become immediately apparent. For the LENR effect to be initiated, normal energy is frequently required as electric power to produce higher temperature, to generate hydrogen ions, or to stimulate the process in various ways. Consequently, the small amount of anomalous energy being sought is frequently superimposed on a large heat flux resulting from normal processes. As a result, the calorimeter must be able to handle large heat flux while being sufficiently sensitive and stable to see the small amounts of anomalous energy. This requirement has severely limited calorimeter design and has complicated evaluation of results. However, as better calorimetry has been applied to the problem, sufficient anomalous power has been reported to completely overwhelm uncertainties in heat measurement. This situation continues to improve as ways are found to generate increasing amounts of anomalous power.

Heat flux can be measured either by noting the temperature drop across a thermal barrier or by measuring the temperature rise of a material, generally a liquid. The first relies on thermal conductivity and the second uses the heat capacity of relevant materials. The isoperibolic and Seebeck methods use the former method and flow calorimetry uses the latter. These three methods will be examined here in detail.

(2***) THESE THREE CALORIMETERS ARE DESIGNED TO MEASURE THE RATE AT WHICH HEAT IS ESCAPING FROM A VESSEL. IN A STEADY STATE IT IS ALSO THE RATE AT WHICH ENERGY IS GENERATED IN A DEVICE INSIDE THE VESSEL. THE CALORIMETERS WE USE IN SCHOOLS OFTEN MEASURE TOTAL AMOUNTS OF HEAT PRODUCED RATHER THAN THE RATE (FOR EXAMPLE WHEN ONE GRAM OF WOOD IS REACTING WITH OXYGEN). THE RATE AT WHICH THE CONSUMPTION OF FUEL TAKES PLACE CAN BE EITHER LARGE OR SLOW.

A calorimeter needs to be calibrated using a known source of energy, the most convenient being Joule heat created at a resistor located within the cell or heat generated during electrolysis of a “dead” cathode. (FOOTNOTE: Newly cleaned platinum does not produce anomalous energy when used as the cathode. However, if the platinum cathode is electrolyzed for sufficient time without cleaning, it may start to produce anomalous energy[1].) This energy must have the same effect on calorimeter behavior as does the process being studied. However, the calibration constant contains systematic errors in addition to normal random error. Both errors may be different from errors occurring when LENR heat is measured. Random error can be evaluated by noting the scatter in repeated calibration values, generally acquired over a range of applied calibration power. The much larger systematic error is more difficult to evaluate and depends on the calibration method and calorimeter design. Also, this error will slowly change with time as various uncontrolled variables change. As a result, data may appear to be very consistent yet be very wrong, sometimes in ways that are hard to evaluate.

This paper describes my experience designing and using three types of calorimeters and applying the designs to a search for heat generated by LENR in electrolytic cells, as pioneered by Pons and Fleischmann[2-4]. Rather than speculating about potential error, this paper examines experimental measurements of many real errors that must be considered. The sources of error found during these studies apply to all calorimetric methods used to study LENR.

II. DESCRIPTION

II.1
Isoperibolic Calorimetry:

(3***) WHAT DOES THE WORD PERIBOLIC MEAN?

Two general types of isoperibolic calorimetry have been applied to electrolytic cells in which LENR is proposed to occur. For the first, called here single wall isoperibolic calorimetry (SWIC), temperature is measured within the

electrolyte and this value is compared to the temperature outside the container, which is generally made of glass, as shown in Figure 1. This method is the least accurate, but the most commonly used of the methods that will be described here.

FIGURE 1 (calorimeter of the first kind)
Cartoon of a Single-Walled Isoperibolic Calorimeter. Dashed arrows show the direction of heat flow caused by bubble action. The top of the electrolyte is warmer than the bottom because warmed water rises from the cathode-anode assembly and energy is lost through the wall as convection causes flow from the top to the bottom near the wall. The measured inside temperature very much depends on where the detector is located.

(4***) WHAT IS “BUBBLE ACTION?”

The inside temperature is determined using thermistors or thermocouples, preferably multiple sensors at different depths and locations, while the outside temperature can be uniform and well known if the cell is contained in or surrounded by a constant-temperature environment. A drawing is shown in Figure 2 of an actual isoperibolic calorimetry. In this case, the cell is surrounded by a jacket through which water flows to maintain constant temperature. Other people have immersed their cells in a fluid bath or within constant-temperature air. The latter method is especially error prone because the true outside temperature at the thermal barrier is difficult to determine with sufficient accuracy.

FIGURE 2. Drawing of an isoperibolic calorimeter using an external cooling jacket. Notice that temperature is measured at two locations within the electrolyte in this cell. This design is typical of cells used to obtain gradient data described in this paper.

(5***) WHAT PRESSURE IS MEASURED BY THE GAUGE? FOR WHAT PURPOSE?

(6***) WHY IS THE ROLE OF THE RECOMBINER NOT EXPLAINED? I WOULD ANSWER THIS QUESTION HERE AND NOT MUCH LATER IN THE ARTICLE.

(7***) IS AIR SEALED HERMETICALLY IN THE DEWAR? I SUPPOSE IT CAN BE SEALED BECAUSE THE VOLUME OF WATER DOES NOT CHANGE (DUE TO THE RECOMBINER). P.S. THIS QUESTION IS ANSWERED IN SECTION **II.6** BELOW.

Accurate calibration and subsequent measurements require the actual average temperature drop across the thermal barrier be equal to the measured temperature drop. Because this ideal condition is seldom achieved, the temperature error must be at least independent of conditions within the calorimeter. Neither of these conditions is easy to achieve because random variations in thermal gradient cause unexpected fluctuations in delta T, even when heat flux is constant. This criticism was raised very early in the field’s history[5]. Figure 3 shows how the gradient within the electrolyte between the top and bottom changes as power is applied to electrolytic action or to an internal resistor.

FIGURE 3. Comparison between the gradient within the electrolyte produced by electrolysis or by power applied to an internal resistor (heater) that is used for calibration.

(8***) WHY ARE GRADIENTS INSIDE THE LIQUID IMPORTANT? MY IMPRESSION, BASED ON FIGURE 1, IS THAT TO CALIBRATE MEANS TO ESTABLISH A RELATION BETWEEN THE GRADIENT ACROSS THE WALL AND POWER.

Notice that the gradient is very small when electrolysis is used, because bubbles stir the liquid, but large when a heater is used. Application of even a small amount of electrolytic power along with heater power reduces the gradient to a value similar to that produced by electrolysis alone.

(9***) WHAT IS THE NATURE OF HEATING BY “ELECTROLYSIS?” IS THIS ONLY I^2*R, WHERE R IS THE RESISTANCE OF THE ELECTROLYTE?

FIGURE 4. Temperature gradients produced using power applied to a heater alone; to electrolysis alone; and when heater power is combined with electrolysis.

FIGURE 5. Effect of applying increasing electrolytic power to a fixed power applied using the heater. The temperature gradient is the difference between the top and bottom of the electrolyte. The heater power is about 10 watts.

(10***) THE X AXIS IN FIGURE 5 IS "ELECTROLYTIC CURRENT" WHILE IN FIGURES 4 AND 5 IT IS "APPLIED POWER." WHY IS IT SO? WAS THE VOLTAGE CHANCING FOR THE DATA IN FIGURE 5?

FIGURE 6. Effect of stirring on the gradient within a cell during electrolysis as a function of applied power.

Figure 4 shows what happens when electrolytic power is applied along with heater power. As shown in Fig. 5, applying even a small amount of electrolytic current can significantly reduce the gradient because bubble action reduces the gradient produced by the heater. This behavior was noted and utilized by Pons and Fleischmann during their early studies and it is why gradients were not important in their work, in spite of assumptions to the contrary[5, 6].

Stirring the electrolyte can reduce gradients, but introduces other problems. Stirring, as shown in Fig. 6, can even reduce the small gradient present during electrolysis. In addition, stirring makes the measurements more stable. Figure 7 compares calibration curves obtained using power applied to electrolysis alone and when power is applied to an internal resistor along with electrolysis. This figure shows that mechanical stirring will reduce but not eliminate the error introduced using resistor calibration.

(11***) WHAT DOES NEGATIVE GRADIENT MEAN IN FIGURE 5?

(12***) WHAT KIND OF ERROR IS BEING MENTIONED? HOW LARGE IS IT ACCORDING TO FIGURE 7?

Mechanical stirring, while reducing the difference between electrolytic and resistor calibration, introduces another error. Stirring reduces the thickness of stagnate fluid next to the barrier, which changes the overall thermal conductivity of the barrier. As a result, the calibration constant changes with stirring rate, as shown in Fig. 8. Consequently, when stirring is used, the rate must be held very constant. The gradient can also change gradually during the experiment causing apparent excess energy to develop. Figure 9 shows the gradient as a function of time. Such changes are very difficult to predict and can introduce serious systematic error if the cell is not frequently calibrated. Application of external magnetic fields will also change the gradient because the path of ions moving between the anode and cathode will be changed, thereby causing flow of heated electrolyte to change. These factors will change the temperature within the electrolyte at positions where temperature is measured.

FIGURE 7.
Calibration curves resulting from power applied to electrolysis or to an internal resistor plus electrolysis while the electrolyte is stirred or not stirred. Delta T is the temperature measured across the cell wall by averaging two thermistors located at the top and bottom of the electrolyte.

Pons and Fleischmann[7, 8] used a cell insulated by a silvered vacuum Dewar through which heat was lost mainly by radiation. Consequently, heat loss was proportional to ΔT^4 through part of the cell and proportional to ΔT through the lid. Energy was applied to a dead cathode in increasing steps and the resulting ΔT was used to calculate a single value for the effective thermal conductivity of the cell over a range of temperature. In addition, the cell was calibrated by applying a pulse of power to a resistor, which caused the temperature to rise and then fall in a manner determined by the heat capacity of the cell combined with heat loss from the cell. This calibration method had the advantage that it allowed sudden busts of anomalous energy to be measured using the rate of temperature change, without having to wait for the cell to stabilize. Several evaluations [9-11]of the method concluded that their procedure was sufficiently accurate to justify some, but not all, of their claims for anomalous energy. However, other studies have not used such a complex calorimeter or used this adiabatic method for calibration.

(13***) WHAT IS THE ADIABATIC METHOD OF CALIBRATION?

Instead, steady-state measurements, where sufficient time is allowed for generated power and the resulting temperature to become constant, give results easier to evaluate.

(14***) I AM STILL CONFUSED ABOUT THE GRADIENTS OF TEMPERATURE. IN FIGURE 1 IT IS BETWEEN INSIDE AND OUTSIDE; IN ALL OTHER FIGURES IT IS BETWEEN DIFFERENT POINTS IN THE SOLUTION.

FIGURE 8.
Effect of stirring rate on the calibration constant. The average temperature across the cell wall was based on the average of two thermistors located at the top and bottom of the electrolyte. The cell was stirred using a Teflon covered cross-shaped bar driven by a rotating external magnet. The calibration constant does not become constant at any practical stirring rate.

(15***) THE LABEL ALONG THE AXIS IS "CONDUCTION CONSTANT" BUT THE FIGURE CAPTION REFERS TO THE "CALIBRATION CONSTANT." WHY IS IT SO?

The outside temperature is generally uniform and well known, except when a cell is air-cooled. Air-cooling introduces additional uncertainty because the temperature immediately next to the container surface is not known and is subject to unstable convection currents even when a fan is used. As a result, loss of heat through the thermal barrier can be very unstable even though temperature of the surrounding air is constant.

Because these errors and ones described below are sensitive to uncontrolled variables even under the best of conditions, the method as commonly used can not be trusted to give absolute values to an accuracy better than ±200 mW, although apparent changes in power at the 20 mw level can be detected. These characteristics make the method poor for making absolute measurements, but adequate for revealing small changes in anomalous power, provided they are part of a consistent pattern using many measurements and if the calorimeter is frequently calibrated using proper techniques. Fortunately, anomalous power is initially absent and grows relative to an initial constant background. Consequently, absolute values for background power are not required as long as the background is stable.

(16***) THAT IS WHAT MY FRIEND ESKIMOS WAS SAYING IN UNIT #151.

Even so, claims for anomalous heat based on this method cannot be trusted if they are less than about 100 mW.

FIGURE 9.
Observed changes in the gradient as a function of time. In this case, a thermistor was located at the cathode in addition to ones at the top and bottom of the electrolyte.

The second method, called double wall isoperibolic calorimetry (DWIC) avoids the gradient problem by using a second thermal barrier outside the cell. A cartoon is shown in Figure 10. Temperature is measured on the inside of this barrier, but outside of the container in which liquid electrolyte is located. Consequently, thermal gradients within the electrolyte have much less effect on measured temperature. As a result, this method is much more accurate than the former and can be made very sensitive, as described by Miles[13] and Huggins et al.[14, 15]. Only the former method (SWIC) is discussed here because its limitations are greater and its use is more common than the DWIC design, even though the latter design is much better. In addition, such cells tend to run hotter for the same applied power compared to the SWIC design, a condition that appears to improve energy production. Details about the design and characteristics can be found in the cited papers.

FIGURE 10.
Cartoon of a double wall isoperibolic calorimeter. Arrows show the direction of heat flow caused by bubble action. The temperature shown as "Inside T" needs to be the average temperature of the cell, which can be obtained using several detectors located in a conducting metal jacket made of copper or aluminum.

II.2

Flow Calorimetry:

Flow calorimetry is more accurate and reliable than is SWIC because it is based on measuring heat energy used to raise the temperature of a known amount of fluid, generally water. Only three quantities need be measured; these being the temperature of fluid entering the calorimeter, fluid temperature leaving the apparatus, and the flow rate. Applied power is then plotted against the flow rate, F (g/min), times temperature increase of the fluid, ΔJ (°C). Corrections must be made for the small amount of heat energy that leaves without being added to the fluid, generally from the cell lid. Generally, this loss is less than 2% of the total amount of energy being produced within the calorimeter and can be determined by applying a known amount of electrical energy to the cell, The stability of such calorimeters is excellent provided they are located within a constant-temperature environment. Because the calibration constant is independent of where heat is produced within the calorimeter, gradients within the electrolytic cell are unimportant. This assertion is easily demonstrated when heat, supplied from a resistor, is compared to heat generated by electrolysis, as shown in Fig. 11. These two methods generate heat in different locations because during electrolysis, bubbles reduce the gradient and heat is generated at the recombiner in addition to at the electrodes. In contrast, a resistor produces large gradients and no heat is released at the recombiner or at the electrodes. Yet, the calibration constant obtained from the two methods is virtually identical.

FIGURE 11. Comparison between values obtained by using electrolysis and/or Joule power. The before and after values were obtained during a study lasting hundreds of hours during which time a cathode produced excess energy. The electrolytic power was based on using a dead cathode.

(17***) I SUPPOSE THE “CALIBRATION CONSTANT” IS THE SLOPE OF THE LINE SHOWN IN FIGURE 11. IS THIS THE VALUE TO WHICH THE CAPTION OF FIGURE 8 REFERRED? HOW IS THE CALIBRATION CONSTANT RELATED TO CONDUCTION CONSTANT PLOTTED ALONG THE Y AXIS IN FIGURE 8?

(18***) FIGURE 11 IS CONFUSING. WHAT IS ^{2}J ALONG THE X AXIS? WHY IS IT NOT DT (DIFFERENCE OF TEMPERATURES)? WHICH TWO TEMPERATURES?

A picture of a flow-type calorimeter is shown in Fig. 12 along with a drawing showing how the parts are related in Fig. 13. Constant-temperature cooling fluid is provided at a location near the input of the calorimeter by pipes containing rapidly flowing water, as shown in Fig. 14. A very small amount of this water is extracted by a precision pump2 which is drawn through the calorimeter.

FIGURE 12. Picture of flow calorimeter. When the Dewar is raised, the stirrer is slipped under it, the top is sealed with an insulating lid, and the surrounding box is closed. As a result, the cell is thermally isolated and the whole apparatus is contained in an environment having a stability of ±0.01°C.

FIGURE 13. Drawing of the flow calorimeter.

FIGURE 14. Diagram showing water flow. By using the valves “A” and “B”, water can be pumped by the bath directly through the cooling jacket to rapidly achieve a constant temperature or flow at a fixed rate determined by the constant rate pump shown near the top of the drawing. The rate is measured by collecting all water passing through the cell in the container located on a balance. This container periodically siphons back into the constant-temperature reservoir. The cell design shown here is different from the one shown in Figs 12 and 13.

Temperature is measured as water enters the jacket and again when it leaves using calibrated thermistors. With valve “B” closed and valve “A” open, full flow water is provide through the jacket to allow the calorimeter to be used in the isoperibolic mode. Flow calorimetry is done when valve “B” is open and valve “A” is closed. Water flow is measured after leaving the constant- flow pump by filling a container located on a balance. Weight is measured periodically to determine the flow rate. The largest error in this method results from variations in flow rate. The calorimeter is calibrated by supplying power either to an internal resistor or performing electrolysis of a “dead” electrode. Figure 11 shows typical calibration values.

(19***) IS IT NOT JUST ONE CALIBRATION VALUE (THE SLOPE OF THE CURVE)?

Experience has shown that the points generally differ from the least squares line by about ±50 mW, generally because of variations in flow rate. In addition, variations in room temperature can change the amount of heat lost through the lid. For this reason, maximum accuracy is achieved when the calorimeter is contained in a constant-temperature environment, as was used in this design.

II.3
Seebeck Calorimetry:

Seebeck calorimetry uses thermoelectric converters within the calorimeter wall to sense the average temperature difference across the wall. The voltage generated by this difference is proportional to the amount of heat passing through the wall, provided the thermal conductivity of the wall is uniform and constant. The major error associated with this method occurs when the walls are not uniform with respect to thermal conductivity or to generated voltage for the same ΔT. If this is the case, the calibration constant will be sensitive to where the cell is located within the enclosure and to random factors that affect convection of enclosed air. Placing a fan within the Seebeck enclosure to force circulation of air can reduce this problem.

An additional problem is introduced if the outside of the wall is not uniformly cooled so that outside temperature is not independent of the amount of heat flowing through each part of the wall. This defect will effectively cause the wall to be nonuniform in its response to heat flow and be sensitive to external temperatures.

A commercial Seebeck calorimeter is available, shown in Fig. 15, which has been used by several laboratories with success. However, this device requires internal fans and a constant temperature environment to realize its highest accuracy. The uncertainty is ±10 mW when the calorimeter is immediately calibrated using a resistor within the electrolytic cell. If the cell is placed as close as possible to the position used for previous calibrations and an average calibration equation is used, the uncertainty increases to ±20 mW. In other words, even slight variations in the cell location will affect the calibration constant, albeit by a small amount.

A homemade calorimeter is shown in Fig. 16. This device uses PVC as a thermal barrier in which 1000 Fe-Constantan thermal couples are inserted and connected in series. The outside of the thermal barrier is in contact with flowing, constant-temperature water. This design is as accurate as the commercial device and is completely immune to changes in room temperature. Similar designs have been used with up to 50 watts of applied power.

Another variation based the on use of thermoelectric panels is shown in Figs. 17 and 18. This calorimeter is three times as sensitive compared to either the commercial device or the homemade example. Figure 19 shows a typical calibration with and without the use of an internal fan. The data show a scatter of less than ±10 mW.

FIGURE 15. Picture of a Thermonetics Seebeck calorimeter3. The active enclosure contains three fans and is closed by the green lid sitting off to the back. After the Seebeck is closed, the surrounding box is closed by another lid, which allows the environment to be maintained at the same temperature (20°±0.02°) as the cooling water provided to the Seebeck enclosure.

FIGURE 16. Photo of a homemade Seebeck calorimeter based on use of thermocouples. A total of 1000 Type J wire thermocouples were placed in the thermal wall made of PVC tubing. The wires were butt welded on the inside and lead soldered on the outside. The outside surface was waterproofed so that constant temperature water could flow in the surrounding jacket. A muffin fan circulates air within the calorimeter when the lid is closed.

FIGURE 17. Photo of a homemade Seebeck calorimeter using 16 commercial thermoelectric panels.

FIGURE 18. Open view of the Seebeck calorimeter made from thermoelectric panels. The top of the electrolytic cell is visible. Next to it is a small fan. Because the chamber is completely surrounded by flowing water, the device is completely inert to changes in room temperature. The active surface of a panel can be seen within the enclosure.

Although the Seebeck calorimeter is insensitive to many errors suffered by the other designs, one problem shown by the

Seebeck also applies to other designs. Because power is normally applied to a cell either as constant current or constant voltage, if the cell resistance changes, the amount of applied power will also change. If this change occurs sufficiently rapidly, with a time short compared to the thermal time constant of the device, an indication of [AN APPARENT] excess power may be seen. This effect occurs because applied power is measured immediately, while the loss of power from the cell takes time to be detected. When applied power, determined by the product of cell voltage and current, is subtracted from power loss, determined by the Seebeck voltage, the apparent difference will not be correct. Figure 20 shows what appears to be [BUT IS NOT] excess power caused by the applied power change shown in Fig. 21. The corresponding negative power associated with a return of applied power to its initial value might be missed if applied power changed at a sufficiently slow rate.

FIGURE 19. Typical calibration for the Seebeck shown in the previous pictures. The curves are not linear because voltage output is not linear with temperature. Use of a fan results in a greater voltage because all panels are not alike in their behavior.

As a result, only the positive component of the change would be seen and attributed to an exothermic reaction. Rapid changes in cooling water temperature can produce similar false indications of excess power. Because these and the other sources of error, false data can occur without warning. A person reporting such data must demonstrate awareness that such processes might be operating at the time of the study.

(21***) TO “DEMONSTRATE AWARENESS” IS NOT ENOUGH. THAT PARSON MUST DEMONSTRATE THAT EXCESS HEAT IS REAL AND NOT ARTIFICIAL.

(22***) ACCORDING TO FIG 19 THE SIGNAL IS IS ONLY ONE MILLIVOLT WHEN THE EXCESS POWER IN ~0.1W (AS IN FIG 20). HOW IS SUCH SIGNAL MEASURED?

FIGURE 20. Apparent excess power created by an artifact.

II.4
Ways Calorimetric Data are used to Calculate Excess Heat Production:

It is important to understand that calorimetry is not an absolute measurement. All values are relative to the behavior when a known amount of power is applied to the device. Consequently, the only requirement for accuracy is for the behavior to remain constant between calibration and during the actual measurement. In other words, energy loss to the environment is not important as long as it is constant, and the value is known based on a suitable calibration.

Calorimetric behavior can be completely analyzed by applying very complex equations[3,6], as a number of authors have done. Such detailed analysis is useful to understand some of the variables expected to affect the results. However, most of the variables revealed by such analysis can be ignored when a suitable design is used. In other words, rather than attempt to correct for deficiencies using correction factors based on mathematical formulation, a better method is to design a device that does not exhibit these deficiencies. As an example of a correction for a deficiency, corrections can be made for variations caused by changes in room temperature by calculating a loss rate through that part of the apparatus that is not at constant temperature, generally the lid through which the wires pass. This method is not as satisfactory as placing the entire calorimeter in a constant temperature environment, including the wires. Such an arrangement insures that the heat loss rate is constant, hence has no effect on the results.

As another example, the generated gas can be allowed to leave the cell and corrections made as described later in the paper. This deficiency and potential error can be easily eliminated by placing a catalyst within the cell to cause all gas to form D_2O before leaving the cell. Worries that such materials would introduce harmful impurities into the cell have been groundless. This approach also eliminates changes in behavior caused by changes in liquid level. When all such deficiencies have been corrected in the design, excess power can be calculated using the simple equations shown below. Although a calorimeter is expected to show linear behavior, the various ignored variables result in nonlinear behavior that can be fit very well by a quadratic equation. Although the resulting constants in these equations have arbitrary

meaning, accurate results require only that the constants not change between conditions existing during calibration and during the search for excess energy, a condition that is easy to evaluate and control.

1. SWIC and DWIC: Excess power = $A + B*\Delta T + C*\Delta T^2 - V * I$, where A, B, and C are constants obtained from the calibration process, ΔT is the temperature drop across the thermal barrier, V (volt) is the voltage applied to the cell at the thermal boundary of the calorimeter, and I (ampere) is the current passing through the cell.

2. Flow-Type: Excess power = $A + B*F*\Delta T + C*(F*\Delta T)^2 - V * I$ where A, B, and C are constants obtained from the calibration process, ΔT is the temperature increase of the flowing fluid, F (g/min) is the flow rate, V (volt) is the voltage applied to the cell at the thermal boundary of the calorimeter, and I (ampere) is the current passing through the cell.

3. Seebeck: Excess power = $A + B*S + C*S^2 - V * I$ where A, B, and C are constants obtained from the calibration process, S (volt) is the voltage generated by the thermoelectric converters, V (volt) is the voltage applied to the cell at the thermal boundary of the calorimeter, and I (ampere) is the current passing through the cell. If a fan is used, power supplied to it also needs to be subtracted.

(23***) IS “THERMAL BOUNDARY” ALWAYS A SOLID WALL? PROBABLY YES.

In all cases, excess power is detected when more heat leaves the calorimeter than is applied to the electrolytic cell.

(24***) I WOULD SAY “EXCESS POWER IS REAL WHEN THE RATE OF LOOSING HEAT IS LARGER THAN THE RATE OF RECEIVING ELECTRIC ENERGY.” THAT IS WHAT THE AUTHOR HAD IN MIND, OBVIOUSLY. THE TYPES OF CALORIMETERS DESCRIBED MEASURE RATES OF LOOSING HEAT, NOT THE AMOUNTS OF LOST HEAT.

(25***) WHAT IS PLOTTED ALONG THE Y AXIS IN FIGURE 20 ABOVE? ARE THESE INSTANTANEOUS VALUES (CALCULATED AS ABOVE) OR AVERAGE VALUES OF THE EXCESS HEAT FOR SHORT TIME INTERVALS? IS IT CORRECT TO ASSUME THAT EACH POINT IS AN AVERAGE FROM TEN OR MORE INSTANTANEOUS VALUES OF EXCESS POWER?

These equations assume that DC power is being applied to the cell. The problem becomes more complex when AC power is applied. Because bubble action rapidly changes the resistance of the electrolyte, a small AC component is introduced into the DC output of the power supply, which does not occur when a calibration resistor is used.

(26***) AHA, THAT WHAT THE “BUBBLE EFFECT” IS? HOW COULD I GUESS THIS WHILE READING THE CAPTION OF FIGURE 1? (TO AVOID SUCH CONCEPTUAL PITFALLS I WOULD ELIMINATE THE REFERENCE TO THE BUBBLING EFFECT FROM THE CAPTION OF FIGURE 1; THERE IS NO NEED OF IT. (YES, THIS IS PEDAGOGY, NOT PHYSICS. KEEP IN MIND,HOWEVER, THAT I AM A TEACHER.)

Experience shows that modern power supplies generate no more than 50 mV of AC superimposed on 15 V and 3 A of DC, which introduces a trivial error when a resistor is used for calibration. If calibration is done using a dead cathode, which generates a similar AC component, this potential error cancels.

II.5
Effect Calorimeter type on the Observed Behavior:

The choice of calorimeter used for such studies determines the temperature experienced by the LENR environment, the time required to achieve steady-state, and the smallest amount of anomalous energy that can be believed. Additional considerations are cost and ease of use.

The amount of heat produced by a LENR reaction is sensitive to temperature at the spot where the reaction occurs. In an electrolytic cell, this location is the surface of the cathode. Each of the calorimeter types removes heat from the cell with different efficiency. Therefore, each type will show a different relationship between applied electrolytic power, resulting

cathode temperature, and the observed excess energy. Because the LENR reaction is sensitive to temperature, the observed behavior will be different, depending on the kind of calorimeter used.

A calorimeter should respond quickly to changes in power so that bursts of anomalous power can be detected, in addition to requiring less time before data can be taken after changes are made. Generally, the smaller the cell, the more quickly the calorimeter will respond.

FIGURE 21. Example of a sudden change in applied power that produced an excess power artifact.

II.6
Consequences of Using Thermodynamic Open Cells:

In order to measure anomalous energy correctly, all energy produced in the calorimeter must leave the device only as heat. When the LENR effect is produced using electrolysis, D_2 (H_2) and O_2 gases are generated. Unless these are recombined back to D_2O (H_2O) within the calorimeter, they will carry chemical energy out of the device. Only if all generated gas is known to leave the cell can the amount of lost energy be calculated and added to the measured value. Otherwise, any unexpected recombination will be interpreted as excess power. Therefore, evaluating the error this effect introduces rests on knowing exactly how much, if any, gas leaves the cell. This problem is eliminated when a catalyst is placed in the cell. Such a design is called a thermodynamically closed system, which is frequently sealed from the atmosphere as well. The problem can also be solved by measuring the exact amount of D2O that is lost during a known period of time at a know applied current.

The energy lost by H_2 and O_2 leaving the cell is calculated as follows. When electrolysis occurs in a cell containing water, H_2 is produced at the cathode and O_2 is produced at the anode. The rate at which these gases are produced is determined by applied current (A) and is calculated using the following equation:

Rate (moles of H_2O decomposed/sec) = A / (2* 96489).

In other words, a current flow of 53.605 Ampere-hours or 53.605 Coulombs will decompose 1 mole of H_2O to give one mole of H_2 and 1/2 mole of O_2.

(27***) THE QUANTITY EXPRESSED IN A*HRS SHOULD NOT BE CALLED “CURRENT FLOW” IT SHOULD BE CALLED ELECTRIC CHARGE. THE SYMBOL I (INSTEAD OF A) I WOULD BE MORE APPROPRIATE FOR THE CURRENT. (YES, THIS IS PEDAGOGY, NOT PHYSICS. KEEP IN MIND,HOWEVER, THAT I AM A TEACHER.)

The energy required to generate these gases is equal to the enthalpy of formation of water (ΔH=68,300 kcal/mole) times the number of moles of H_2O consumed.

Consequently, the energy (E) used to create these gases can be calculated using the following equation:

$E = \Delta H * A * t / (96489 * 2)$ ---------(1)

where E = kcal of energy used during the time “t” (sec). The amount of lost energy (power in watts being lost) can be calculated another way as follows:

$P = E * 4.189 / t$ ----------(2)

Watts = volt * current -------(3)

Substitution of Equation 1 into Equation 2 and the result into Equation 3 gives, upon rearrangement, the following equation expressed in volts.

Volt = (68300 * 4.189)/(2*96489) = 1.48 volts

When current applied to the cell is multiplied by this voltage, power being used to decompose water can be calculated for standard state conditions (STP). In other words, Equation 1 has been rearranged to allow the calculation to be made by a single multiplication. The voltage has no meaning except as a constant that results from combining Equations 1, 2 and 3. If the conditions do not correspond to STP, small corrections will be required. A similar calculation can be made for D_2O to give a value of 1.54 V.

(28***) GREAT; I HAVE OFTEN SEEN THESE NUMBERS BUT HAD NO IDEA HOW CAN THEY BE JUSTIFIED. THANKS, ED.

For convenience, this value is called the "neutral potential" for water decomposition because it is the theoretical voltage required to produce a current flow through a cell that results in decomposition of water. Real cells will require different voltages to initiate current flow, depending on conditions existing in the cell. Such measured voltages cannot be used to calculate the amount of energy lost from the cell unless the exact nature of the chemical reactions is known.

(29***) WHY IS IT SO; MY IMPRESSION WAS THAT WHAT IS MEASURED IS MORE RELIABLE THAN WHAT IS THEORETICALLY EXPECTED.

Unless the cell contains a catalyst known to completely convert all gas to liquid water, the amount of gas that leaves a cell can be variable and related to applied current, as shown in Fig. 19 [FIG 22]. Small areas of metal exposed to the gas can cause some recombination in excess of values shown here. Nevertheless, application of current above about 100 mA reduces the amount of recombination within the cell to insignificant values.

(30***) WHY IS THE "SPONTANEOUS" RECOMBINATION REDUCED AT LARGE CURRENTS?

FIGURE 19. Relationship between applied current and amount of recombination within a cell in the absence of a catalyst.

(31***) IT IS REALLY FIGURE 22 (NOT 19)

In my work, the cells communicated to an oil reservoir, as shown in Fig. 20 [Fig 22]. This arrangement allows the D/Pd ratio of the palladium cathode to be determined because accumulation of orphaned oxygen, produced when D2 reacts with the Pd cathode, transfers mineral oil to the balance.

(32***) THIS IS NOT EXPLAINED CLEARLY ENOUGH FOR ME.

Because this arrangement gives about 4200g of oil for each mole of D retained by the Pd, it provides a very sensitive method to determine the D/Pd ratio. (This number depends on atmospheric pressure. The quoted value is for average pressure at 8300 feet, the elevation of my laboratory.)

(33***) IS g EQUAL TO 9.8 m/s^2? I WOULD PREFER TO SEE METERS FOR THE ELEVATION, NOT FEET.

Failure of the recombiner is immediately revealed by a steady increase in displaced oil even after the Pd has reached its maximum D/Pd ratio. The data (Storms) shown in Figure 19 [Fig 21] was obtained by removing the catalyst and measuring the amount of generated gas using this arrangement.

FIGURE 20. Drawing of the oil storage and weighing system. Any gas generated in the cell displaces oil onto the balance. Suitable calibration allows this method to measure the D/Pd ratio of the cathode to ±0.001, to determine the amount of recombination in the absence of a catalyst Fig. 19 [Fig 21], and to demonstrate that the catalyst is working properly.

(34***) IT IS REALLY FIGURE 23 (NOT 20)

II.7
Consequence of Prosaic Processes Occurring Within the Calorimeter:

A number of prosaic processes have been suggested that have been previously evaluated by Storms[16, 17]. If real, these processes, as well as others that have not yet been suggested, have the potential effect of producing either extra energy that is interpreted as energy resulting from the proposed cold fusion processes, or using energy, which is frequently interpreted as an obvious error.

(35***) WHAT IS "USING ENERGY" IN THIS CONTEXT? IT IS USE OF ENERGY STORED IN THE SYSTEM, AS EXPLAINED IN THE NEXT SENTENCE. I DO NOT KNOW WHY THE TERM "PROSAIC PROCESS" WAS INTRODUCED. THE TERM "STORAGE PROCESS" IS BETTER, I THINK. (YES, THIS IS PEDAGOGY, NOT PHYSICS. KEEP IN MIND,HOWEVER, THAT I AM A TEACHER.)

A problem is created if the prosaic process absorbs energy for a while, hence is ignored, and then releases this energy, which is then interpreted as evidence for an anomalous effect. However, for such a process to operate, a chemical or physical mechanism must be present that can store and then re-lease large amounts of energy. No one has yet identified such a mechanism when only Pyrex, D_2O, Pt, and Pd are present, the main constituents of a Pons-Fleischmann cell.

(36***) IN FIGURE 2 I ALSO SEE TELON AND RUBBER (O-RING). WHY ARE THESE SUBSTANCES NOT MENTIONED?

Other methods, such as gas loading or ion bombardment, found to produce anomalous heat using different materials, would each have to be consistent with the proposed prosaic processes for the mechanism to be a plausible explanation. In addition, Rejection of the results based on prosaic processes requires that many different prosaic processes are operating, all giving the same result, or the same prosaic process is operating under many different conditions. So far, none of the suggested prosaic processes meet these conditions.

III. SUMMARY

Calorimetry applied to the LENR phenomenon has evolved since 1989 and is now close to the state of the art for measurement of energy production. The Seebeck method provides the most stable and most accurate method, as suggested previously by Bush[18]. Such calorimeters can now be made easily with very little cost or purchased from commercial sources. Nevertheless, even the simple single wall isoperibolic (SWIC) method can be made useful if factors that affect behavior are well understood and are taken into account when the results are analyzed. Unfortunately, reasons for early rejection of such data were based on a very limited and generally incorrect understanding of calorimeter behavior.

(37***) MANY PEOPLE ARE NOT AWARE OF THIS IMPORTANT FACT. THEY THINK THAT CALORIMETRY WAS ALREADY CLOSE TO "THE STATE OF ART" ONE HUNDRED YEARS AGO. (TINY EXCESS HEAT FROM RADIUM WAS DISCOVERED BY P. CURIE IN 2003). NUANCES DESCRIBED BY STORMS BECOME IMPORTANT IN A CONTEXT IN WHICH EXCESS POWER, EP = (B - A), IS A SMALL NUMBER (0.1 to 1 W) IN COMPARISON WITH NEARLY EQUAL (AND MUCH LARGER) NUMBERS, B AND A. NOTE THAT B REFERS TO THE THERMAL OUTPUT POWER WHILE A REFERS TO THE ELECTRIC INPUT POWER.

This study has resulted in the following issues and conclusions:

1. The SWIC method cannot be calibrated using an internal resistor to apply Joule heat. Accurate calibration can only be obtained using a dead cathode and passing current through the electrolyte. Stirring is beneficial.

2. Flow-type and Seebeck calorimeters can be calibrated using an internal resistor within the cell because the results are

independent of where heat is produced within the electrolytic cell.

3. The major error in flow calorimeter involves achieving a uniform and known flow rate.
4. The major error in Seebeck calorimeter involves maintaining a uniform temperature at the outside of the thermal barrier and good circulation of air within the enclosure. Air-cooling of the outside cannot be relied on to give stable results.

5. A constant temperature environment, which is able to effectively carry the heat away, must completely enclose all calorimeters. Use of air-cooling as the major method to remove heat is not satisfactory and will not give stable results.

6. In general, the simpler the method and the less complex the data analysis, the more easily the results can be believed.

Numerous laboratories, using three different types of calorimeters having a variety of designs and characteristics, have studied the LENR effect and report the same anomalous behavior. This kind of reproducibility is much more significant than the ability of a particular researcher to make the effect work on demand, as many skeptics demand. Indeed, as conditions needed to create anomalous effects have become better understood, researchers who use this knowledge now produce the effect with good success.

(38***) THE DIFFICULTIES WOULD BY REDUCED IF THE EXCESS POWER WERE A LARGER FRACTION OF THE ELECTRIC INPUT POWER (FOR EXAMPLE 10%). THE CALORIMETRIC PROBLEMS DESCRIBED IN THIS ARTICLE HAVE NOTHING TO DO WITH MECHANISMS THROUGH WHICH THE EXCESS POWER IS GENERATED IN AN ELECTROLYTIC CELL. THE MECHANISM CAN BE COLD FUSION OR SOMETHING ELSE.

Acknowledgements
Many people have contributed to my studies of calorimetry. In the past, Charles Entenmann, Jed Rothwell, Dave Nagel, and Gene Mallove provided financial support at various times without restrictions. Their selfless support of cold fusion has made possi-ble much of the understanding described in this paper. Since 2003, Lattice Energy, LLC has exclusively supported my work in LENR. My wife Carol has been most patient and provided food and drink when I was too engrossed to get it for myself.

156) Two papers of Lipson et al.

Ludwik Kowalski (7/6/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

According to Karabut (1), who used a Pd target in a glow discharge chamber, the rate of emission of energetic particles (alphas of 14 MeV) was about 1 per second. The glow discharge parameters were about 1000 volts and 450 mA. Lipson, however (2), using a Ti target in a similar apparatus (at the 2175 volts and 250 mA), reports the rate of 0.12 (plus or minus 0.02) per second. Does this big difference result from the use of different discharge parameters or from differences between the two cathodes? My guess is that Pd is a much better target than Ti, in terms of the yield. Why was this not discussed by Lipson? Would it be reasonable to work with Pd to get better statistics?

In another paper Lipson et al. (3) focus on the effect of the glow discharge voltage on the rate of cold fusion from Ti. Their figure 6, for example, shows that the yield of 3 MeV protons, increases from about 50 units at 805 V to 250 units at 2175 V. The units are tracks per cm^2, at the same geometry and same current. The absolute yields, according to Figure 5, range from 1300 and 1550 protons per second. This seems to indicate that protons are dominant particles; the rate of emission of more energetic charged particles, according to 2, is only 0.01 per second, as indicated above. This can be compared to the protons/alphas ratio in experiments based on electrolysis. According to (2) that ratio is 6:1. Why is the protons/alphas ratio in the glow discharge (equal 1450/0.012) much larger than in the electrolysis? Why was this question not addressed by Lipson et al.?

157) Comments and questions

Ludwik Kowalski (7/8/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

In unit #150 I posted comments and questions related to a paper on calorimetry. I was prompted by a message from Richard Eskimos. In this unit I decided to do the same about a paper on unexpected charged particles. In planning to start a research project in that area, using CR-39 detectors, I selected a paper published by Andrei Lipson, and his coworkers. They are experts in using track detectors of charged particles in the area of cold fusion. The title of that paper is **"Phenomenon of an Energetic Charged Particle Emission From Hydrogen/Deuterium Loaded Metals;"** it can be downloadable from the www.lenr-canr.org website.

That paper, like the one chosen to ask questions about excess heat, was presented to experts attending the 10th International Cold Fusion Conference. It is not surprising that somebody who has not read earlier papers has difficulties with understanding numerous detail. As in unit #150 I want to ask questions illustrating difficulties encountered by non-experts in reading conference papers.

What follows is the text part of the article with questions and comments (in red). The four authors of this paper are A.G. Lipson, A.S. Roussetski, G.H. Miley and E.I. Aaunin. They represent prestigeous research centers: (a) University of Illinois at Urbana-Champaign, Department of Nuclear, Plasma and Radiological Engineering, Urbana, IL, (b) Lebedev Physics Institute, of the Russian Academy of Sciences and, c) Institute of Physical Chemistry, of the Russian Academy of Sciences. The text of the paper (without figures) is in black while my comments and questions are in red. Will the answers to my questions be provided by some readers? I hope so. It will not be difficult to incorporate such input into this text by using a different color.

Abstract
The new phenomenon of energetic alpha (up to 16.0 MeV) and proton (~1.7 MeV) emissions has been discovered from a metal surface possessing a large affinity for hydrogen and loaded/excited by electrolysis, glow discharge or powerful laser. These various experiments on charged particle detection show a remarkable feature, namely all exhibit a similar specific energy yield of long-range alphas (1 alpha particle per 10-15 eV input energy/Pd(Ti) target atom) independent of the excitation power of delivering method (electrolysis, glow discharge or laser irradiation). This result suggests the mechanism of energy transfer causing the energetic particle emissions in hydrogen loaded metal targets is similar despite the seemingly dissimilar excitation techniques.

I. Introduction
Charged particle emissions from the surface of Pd and Ti deuterides have been studied since the beginning of experiments on Low Energy Nuclear Reactions (LENR) product detection in metal deuterides. First experiments on this charged particle detection were mainly, referenced to confirm generation of DD-reaction products (3.0 MeV protons and 1.0 MeV tritons) in metal deuterium system. However, alongside with charged DD-reaction products, there were appeared reports concerning detection of more energetic particles than would be expected from DD-reaction [1-4], especially during hundred-keV accelerator deuteron

bombardment of Ti and Pd targets.

Earlier we just reported that during exothermic deuterium or hydrogen desorption we found high energy alpha-particle emission in the energy range 8-14 MeV, that could not be ascribed to known natural alpha -- emitters. Indeed, the typical charged particle spectrum taken in vacuum using SSB -- detector during about 8 days shows no counts beyond a 8.0 MeV energy (Fig. 1 [5]).

(1***) The SSB probably stands for the “Solid State Barrier,” a common Si detector.

Figure 1.

That is not surprise because maximal alpha energy of radon series is about 7.8 MeV, while energy of cosmic induced protons rarely exceeds 2.0 MeV. In contrast to Background, the dE-E spectra detected from Au/Pd/PdO:D(H)x samples during exothermic deuterium desorption clear showed presence of high energy alpha-component (Fig.2 [6]).

(2***) What are the horizontal segments in the second bin (0.5 to 1 MeV)? I am referring to Figure 1.

Figure 2

New insight was recently obtained from the use of CR-39 track detectors to the study energetic particle emissions from the surface of Pd/Ti loaded with hydrogen/deuterium [7]. Experimental runs with CR-39 to detect long-range alpha-particles *in-situ* during electrolysis of Pd/dielectric substrate cathodes showed energetic alphas ($9 < E_a < 16$ MeV) yield $N_a \sim (2\text{-}5)*10^{-4}$ s^{-1} -cm^{-2} Pd in 4π-str accompanied by even more intensive emission of ~ 1.7 MeV protons.

The objective of present research was focused to study energetic charged particle emission (ECPE) at various power loading and/or excitation conditions applied to the metals with large affinity to hydrogen/deuterium and determine a specific yield of ECPE, depending on excitation power applied to the sample.

II. Experimental Technique

For charged particle detection the purified “Radtrack” CR-39 plastic track detectors (with the size 2.0*1.0 cm^2) by Landauer Inc. AND Fukuvi Chemical have been used. Especial purification procedure utilized for detector manufacturing as well as hermetic saving condition allow to minimize initial alpha track density of these CR-39 to less than 20 cm^{-2}.

(3***) In other words less than 40 tracks per detector. A useful number to know.

Figure 3a and Figure 3b

(4***) Good to know that Radtrack and Fukuvi detectors are not different. Is it true that Fukuvi detectors are no longer commercially available?

These detectors were calibrated with alpha-sources (in the range of 1.6 – 7.7 MeV) and by monoenergetic cyclotron alpha-beams (in the energy range of 10.0 – 30.0 MeV) as well as by proton beams with energy ranging of 2.0-3.0 MeV. (**Fig.3a,b**). For energetic proton detection the detectors were also calibrated with Van DeGraaf accelerator by monoenergetic proton beams (energy ranging from $0.75 \le E_p \le 3.0$ MeV), (Fig.2). After the beam exposure detectors were etched in 6N-NaOH at t=70°C during 7 hrs. and investigated with optic microscope. Typical view of alpha-track picture is presented in Fig 4. As seen, at normal interaction

of monoenergetic cyclotron beam with detector, the tracks observed after the etching have almost ideal circle-like shape. These nuclear tracks can be easy distinguished from the defects of CR-39 subsurface structure.

Figure 4

The efficiency of CR-39 detection with respect to different energy alphas and protons were estimated in accordance with their critical angles q_c being determined by formula [4]: q_c= sin-1{[1-(dE/2h)2]/[1+(dE/2h)2]}, where dE-is the track diameter produced by charged particle with energy E (Fig 1,2), and h = 9.1μm is the depth of etched layer in CR-39 at our etching condition. Knowledge of the critical angles calculated from above formula allow to determine the efficiency e of the charged particle detection as:

e = 0.5 * (1-sin q_c)

(5***) This is wrong; replace sin by cos. Efficiency is defined as the ratio of the solid angle over 4*p. I suppose they reprint the same mistake from the 2002 paper (ICCF9 in China). Am I the first one who noticed it? I do not think that the reference 1 has anything to do with the efficiency of CR-39 detectors.

In electrolysis experiments the freshly opened CR-39 detector chips were attached either to the Pd thin film cathode(Foreground)

(6***) It is not clear to me how to apply CR-39 to a cathode during the electrolysis. They used a very thin cathode. Somehow (according to their 2002 paper at ICCF9 in China) they placed the Cr-39 detectors (open and shielded) inside the electrolyte, next to the thin cathode. This if not at all obvious from reading this paper. Why there is no illustration? Why there is no reference to their earlier paper at this place?

or to the substrate side or/and immersed in electrolyte in the cell (Background).

(7***) This formulation (with two “or”) is confusing. I would measure the background by placing the CR-39 detectors next to an identical cathode that has not been loaded with hydrogen, for example, at zero current. I will assume they did this.

Background experiments showed proportional growth of track density vs. time for CR-39 immersed in electrolyte (Fig.4). At large Background duration [long exposure] it is possible to observe two separate alpha-peaks with track diameters located at 8.0 and 9.0 μm, respectively (Fig.5). The energy positions of these peaks are in good agreement with conventional alpha-Background and are normally corresponded to about 7.0 MeV radon (8.0 μm) and 5.0 MeV (9.0 μm) thoron series of natural alpha-nuclides.

(8***) In other words, the electrolyte or cathode (or both) contained traces of emitters of natural alpha particles.

Figure 5

(9***) According to this figure they can distinguish diameters differing by only 0.1 m.

In order to separate high-energy alphas and low-energy protons that could be possibly emitted during electrolysis runs, the thin Cu-foils (25 μm thick) were inserted between the cathode metallic coating and the CR-39 surface. 25 μm Cu coating is completely absorbs all alpha-particles and protons with energies below 9.0 and 2.3 MeV, respectively.

(10***) I suppose that a separate experiment was conducted to show that the foil itself is not alpha radioactive (at a very low level). Why is nothing said about this? Alpha particles from the surface of the foil, interpreted as if they were traversing the foil, could be assigned more energy than they really have.

Background measurements in experiments with Cu-covered CR-39 were performed similarly to that with open detectors. As expected, these background experiments showed significant reduction(~2 times) in the total track density compared to that obtained with open CR-39 detectors.

(11***) Why “as expected?” On what basis could one expect that one half of all tracks recorded with the open detector (without the Cu foil) would be due to low energy alpha particles and protons? I suppose this was based on their earlier data. How else would one predict the percentage of low energy particles (such as 50%)?

(12***) How large were these densities? What about errors of judgment in deciding which tracks to count and which to attribute to surface defects on CR-39? Based on my limited experience, I suspect that the adjective “typical”, used above to describe Figure #4, might be an exaggeration.

In experiments with glow discharge and laser irradiation for particles identification and their energy estimation, we used CR-39 Fukuvi detectors covered with Al or Cu foils with the thickness in the range of 11-66 or 25-50 μm, respectively. The experimental set ups used for deuterium glow discharge Ti-cathode bombardment and for powerful picosecond laser irradiation of Ti and TiDx targets are described elsewhere []. Power densities applied to the loaded/excited Pd or Ti samples (with respect to the total sample volume) during the electrolysis experiment, in glow discharge (GD) bombardment and in Laser irradiation are estimated as (2-5)x10^2, 10^5-10^6 and ~10^{21} W/cm^3, respectively.

(13***) Why per cubic cm and not per square cm?

In series of experiments with GD the detectors covered with 11-33 μm Al foils were placed behind the holes drilled in the Mo anode at the distance of 3.0 cm from the surface of Ti cathode.

In the laser experiment detectors, shielded with 11-66 μm of Al or 25-50 μm of Cu were placed at different angles toward the target (20 cm from the front of the target perpendicular to the beam direction and 4 cm distance behind the target)

Utilization of shielding foils of various thickness alongside with CR-39 calibration data allow identify and roughly reconstruct energy spectra of emitted alpha particles and protons.

III. Experimental Results

a. Electrolysis

The Foreground runs with electrolysis of Pd-thin film cathodes the exposed CR-39 detectors (t~2.0-30 days) showed the appearance of unusual diameter tracks that were not observed in Background detectors exposed in the same electrolytic cell. Indeed, in the track diameters distribution N(d), two significant peaks located at 7.0m and 6.0m observed in the Foreground runs (with electrolysis) with opened CR-39 detectors (Fig 6).

Figure 6

At the same time, almost no counts for tracks with d < 7.5m was found in the corresponding Background runs for detectors exposed in the same electrolytic cells.

(14***) I replaced mm by microns (mm instead of mm was an obvious typing error).

The low diameter tracks appeared to accompany an electrolysis of the thin Pd-film and Pd-black cathodes. The intensity of charged particle emissions and ratio between 6.0 and 7.0 μm peaks during electrolysis are strongly depended upon the cathode history and structure (Table 1). It should be noted that generation of charged particle emissions during the electrolysis of thin Pd cathodes has a good reproducibility (in contrast to the irreproducible emission of DD-products in Pd-D systems).

(15***) According to Karabut, emission of charged particles is highly reproducible when Pd is bombarded with D (glow discharge). Is it a contradiction?

In the Foreground runs with the same cathode being carried out with 25 μm Cu-film shielded CR-39 chips, the 7.0 and 6.0 mm peaks disappeared. But the other maximums ranging from 7.5 to 11.4 mm have appeared that were not found in Cu-shielded Background detectors (Fig 7).

(16***) This discussion of differences between Figures 6 and 7 is not clear to me.

Figure 7

The experiments with Cu-shielded detectors and a knowledge of CR-39 calibration curves (Fig 1,2) allowed to identify the energy and type of particles emitted in the Foreground runs with open CR-39 detectors. Taking into account stopping powers and ranges of 25 μm Cu-film with respect to the alphas and protons with different energies, the initial energies of emitted particles were also calculated. Comparison of pictures obtained with opened and shielded detectors shows that 6 μm peak is completely disappeared while a broad near 7.0 μm peak in Fig. 6 shifted to the larger track diameters and split at least by 3 narrow peaks (Fig 7). Disappearance of 6.0 μm peak in a shielded detector indicates to the low MeV proton nature of this peak. In accordance with our calibration data the estimated proton energy would be within 1.5-1.7 MeV (Fig 8a, b [7]).

Fig 8 a Fig. 8 b

(17***) Figure 8a has a line saying “39 detectors;” it is confusing. The “open Cr-39 detectors” should be in one line. And what is “25 mcmCu/CR” below that line?

(18***) Why are figures 8a and 8b not labeled consistently? Their legends are in different places.

(19***) These two figures show that 20 alpha particle tracks and 120 proton tracks were recorded on 3 cm^2 of Cr-39? Can this 1:6 ratio be interpreted in terms the higher Coulomb barrier penetrability of protons with respect to alpha particles?

(20***) How long did it take to accumulate so many tracks? A person attempting to reproduce the experiment would need to know this. In other words, what was the average emission rate? Information about the electrolytic cell should also be provided.

In contrast to 6.0 μm peak, the 7.0 μm maximum, accordingly to its shift and splitting after crossing the Cu-shield should be ascribed to a broad 11-16 MeV alpha-peak. Indeed, the stopping range of alphas ranging from 11-16 MeV (for open Cr-39) would be consistent with observed narrow bands with energies 11.6, 12.5 and 14-16 MeV, respectively for Cu-covered detectors (Fig 8a). Due to higher resolution of CR-39 alpha-tracks for the lower energy particles (Fig 1) the broad 11-16 MeV alpha band could be observed as the single individual maximums after these particles crossed the Cu-foil. Therefore, we showed that electrochemical loading of Pd thin film cathodes on dielectric substrates unambiguously produce high-energy charged particles: 1.5-1.7 MeV protons and 11-16 MeV alphas.

b. Glow Discharge

Let us consider in details new results on ECPE obtained for more powerful loading process during low energy deuteron bombardment of Ti-cathode. Typical spectra of charged particles emitted in such GD obtained with 11 and 33 μm shielded CR-39 detectors are shown in Fig 9.

Figure 9

(21***) This figure shows ~80 tracks/cm^2 in 7 hrs (50+20+10=80). It also shows that diameter become wider (lowering of energy) when a thicker shield is inserted. But why didn't they show diameters (and numbers of tracks) detected with the unshielded detectors? Does it mean that using unshielded detectors is not possible in the case of their glow discharge experiments?

As seen, the spectrum of charged particles of 11 μm shielded CR-39 contains 3 characteristic peaks with track diameters 5.2, 6.2 and 7.2 μm, respectively. In accordance with Fukuvi Cr-39 calibration those peaks have to be corresponded to 3.0 MeV protons (5.2 μm), 1.4 MeV/2.8 MeV protons /deuterons (6.2 μm) and 13.0 ± 2.0 MeV alphas (7.2 μm). Indeed, increase in Al shielding thickness from 11 to 33 μm leads to corresponding increase in track diameters for all three peaks observed at for 11 μm Al-covered Cr-39 detectors.

(22***) The above text is too condensed, for my taste. They interpreting say the peaks with track diameters 5.2, 6.2 and 7.2 μm. The first is due to protons of 3 MeV, the second is due either to to 1.4 MeV protons or 2.8 MeV deuterons, and the third is due to 13 MeV alphas. The last sentence is confusing, unless the phrase "observed at for 11 mm Al-covered Cr-39 detectors" is removed. They probably say that all red peaks (even single counts) shift to the right (diameters become larger).

The shifts of these peaks (5.2 →5.6 μm; 6.2 → 6.6+6.8 μm (spitting) and 7.2 →7.6 μm) is really corresponded to the energy losses of 3.0 MeV protons (from DD-reaction), 2.8 MeV deuterons and 13.0 MeV alphas, in accordance with the stopping ranges of these energetic particles in Al. In Fig. 10 the more detailed picture of alpha emission is presented and compared to the background in GD chamber.

Figure 10

As seen from the Fig. 10 the energetic alpha emission in GD at given discharge parameters exceeds the background counts in the range of 7.2 μm track diameters about 25 times.

(23***) I can not see this from Figure 10. By the way, why some blue background bars indicate negative negative densities? But I do see that this time they refer to Al shielding (while Figure 9 referred to Cu shielding). I suppose it was the same experiment in which some detectors were covered with Cu and others with Al. It looks that they had about 45 tracks/cm^2 in 7 hrs.

At the same time the usual alpha-background (d ≥ 8.0 μm) in presence of GD is not significantly distinguished from that in absence of glow discharge voltage. The yield of energetic alphas after background subtracting was found to be Nα = 0.12 ± 0.02 a/s in 4π ster.

(24***) But according to Karabut, who used the Pd target (not Ti target) the rate of emission of energetic alphas (at 1000 volts) was about 1 per second. This is nearly ten times more than the above number. Why is this not discussed? I would use Pd to increase the yield?

This yield of energetic alphas is about 2-3 orders of magnitude high than that detected in electrolysis experiment.

(25`***) Aha, here is the answer to my previous question; for the electrolysis the rate was about 0.001 to 0.0001 per second.

The yield of 2.8 MeV deuterons in GD experiment is about 2-3 times larger than for alphas.

(26***) Can this ratio also be interpreted in terms the higher Coulomb barrier penetrability of deuterons with respect to alpha particles? What I have in mind is a barrier lowered by screening.

In Fig. 11 the spectra of charged particles obtained for two different GD voltages are presented.

Figure 11

As it is expected the 3.0 MeV peak from DD-reaction in Ti under deuteron bombardment is strongly depended on GD voltage. Meanwhile, the intensities of 2.8 MeV deuteron and 13 MeV alpha peaks are depended on the GD voltage much weaker.

(27***) On what basis is this expected? Why should the effect of discharge voltage on the probability of emission of DD protons be much more pronounced than on the probabilities of emission of more more energetic particles?

In Fig 12a and 12b the more detail pictures of dependencies shows This fact indicate to absence of direct connection between energetic charged particle emission and DD-reaction. The detailed yield dependencies for 3.0 MeV protons, 2.8 MeV deuterons and 13.0 MeV alphas on discharge voltages in the range of 0.8-2.45 kV are presented in Fig 12 a, b.

Figure 12 a and Figure 12 b.

As seen, the yields of energetic deuterons and alpha particles normalized to the effective discharge power almost independent on deuteron energy Ed, while DD-reaction yield of 3.0 MeV protons tends to grow exponentially with increase in Ed. The experiments showed that the yields of energetic deuterons and alpha particles in Glow discharge are roughly proportional to GD power applied to the Ti cathode (Fig. 13)

Figure 13

(28***) Zeros below the x axis should be replaced by numbers of watts.

The fact of near linear dependence of energetic charged particle emission yields on effective power applied to the Ti cathode leads to a simple assumption that the yield of ECPE from the surface of metals with large affinity to hydrogen could be further increase with increase in specific power applied to these metals.

c. Laser Experiment

(29***) Their laser induced fusion is probably not cold. This is the end of my questions and comments.

In order to check the assumption of ECPE yield increase with applied specific power we have performed a search of energetic alphas in ultra-high specific power applied experiments on picosecond laser excitation of Ti/TiHx and TiDx targets. The details of this experiments, including set up are described in another report published in this Proceedings [8]. We note here that powerful laser irradiation of solid targets (polymers and

some metals including Al , Pb LiD and so on) was studied during last 10 years to induce intense MeV protons and heavy ion emissions as well as to the purposes of inertial DD-fusion and isotope separation (see review article [9]). Here in experiments with powerful laser we, probably, first use targets possessing large affinity to hydrogen/deuterium (Ti and TiDx foils of 30 μm-thick). The parameters of laser were: power density $P=2x10^{18}$ W/cm^2, pulse duration $\tau = 1.5x10^{-12}$ s and wave length $\lambda = 1.054$ μm. To compare our results with usually employed targets (to produce intense proton beams) we also used polyethylene (PE) film targets of 35 μm-thick.
The main charged particle component emitted on laser shots with both Ti(TiDx) and PE targets was found to be protons (deuterons) with energies Ep ≤ 1.0 MeV (Np ~ 10^{11}/pulse). The heavy ion component with mass A > 4 was also detected. However, besides these species during the shots on Ti and TiDx targets we found we found also energetic alpha particles that were not detected in experiments with PE (Fig.) As seen the laser shots on Ti-target produce the same tracks at the CR-39 detectors covered with 11 μm of Al (d=7.2μm) that were detected for of electrolysis and GD loading experiments. The similar shots on PE target showed possible alpha emission level comparable with background in vacuum chamber of target installation.

Figure 14

In Fig. 15 the spectra of alpha particles detected in the same laser shot by CR-39 detectors covered with various shielding and placed between 0-30 ° with respect to TiDx- target are presented.

Figure 15

The main peak in Fig 15 corresponding to 13.0 ± 2.0 MeV alphas is shifted to larger track diameters for 33 and 66 μm Al shielded detectors, well in accordance with 13 MeV alphas stopping range in Al. For 50 μm Cu covered detector this peak is completely disappeared because the 50 μm thick Cu shielding will stop all alpha particles with energy E ≤ 15.0 MeV.
The same energy alpha-particle emission, but about 30 times less in intensity was detected from the opposite side of Ti/TiDx target (the angle between the detector and target • = 180°) (Fig 16.) Here as in Fig 15. a track diameter corresponding to alpha peak (d=9.9 μm) is also in good agreement with stopping range of 13.0 MeV alphas in the sandwich consisting of Cu-shielding and Ti-foil [25μm Cu(shielding) +30 μm Ti(sample thickness)]. This fact allow assume that alphas were originated mainly at the front side of the Ti target. The estimated average intensities of alpha emission from the front and opposite sides of Ti/TiDx targets (taking into account geometrical efficiency of measurement) was found to be If ~ $2x10^4$/pulse-sr-1 sr. and Io ~$7x10^2$/pulse- sr^{-1}, respectively.

Figure 16

In Fig 17 the results of alpha-spectra reconstruction from CR-39 data obtained for various shielding type and thickness (taking into account cyclotron calibration) are presented. The results of such reconstruction for Ti and TiDx targets within experimental error are close one to another. In the Fig. 18 a comparison of alpha spectra obtained from laser experiment with Ti-target and Pd-glass electrolysis are shown. As seen from this figure, the spectra of laser experiment and electrolysis detection look quite similar within the measurement error (determined by standard deviations of alpha-calibrations and errors of track diameter measurements) and both spread in the energy range of 10^{-17} MeV.

Figure 17 and Figure 18

IV Discussions and Conclusions
Thus, in three independent studies of ECPE during hydrogen(deuterium) loading of Pd and Ti targets or excitation of their hydrides/deuterides, the similar energetic alpha particles and protons/deuterons are found

to be emitted, despite the seemingly dissimilar loading/excitation techniques. We found that the absolute intensity of ECPE is roughly proportional to the specific power applied to the metal target during its loading or excitation (Fig 19). There are three different power density areas corresponding to the studied ranges of specific power applied in experiments on ECPE detection with hydrogen/deuterium loading/excitation of Ti and Pd: electrolysis -((2-6)x10^2 W/cm^3); GD -(10^5-10^6 W/cm^3) and laser irradiation - (~ 10^{22} W/cm^3) are presented in this graph. On the other hand, the specific energy required to emit one alpha particle (E > 8.0 MeV) in all these loading /excitation cases was found to be Es = 17 ± 8 eV/at.Ti(Pd) and practically independent on excitation power applied to the target (Fig. 20).

The discovered property of the metals with large affinity to hydrogen to emit energetic charged particles is probably concerned to peculiarities of these metals. On one side, during hydrogen loading the metals such as Pd and Ti are subjected to strong plastic deformation accompanied by massive generation of non-equilibrium phonons. On the other side, the metals with large affinity to hydrogen may capture high amount of helium (from surrounding atmosphere or during the loading alongside with hydrogen), which have tend to segregate in the site of high internal strain. We assume that loading or excitation procedure produce non-equilibrium phonons in the near-surface layer of Pd or Ti. These phonons would be focused (concentrated) in the some specific sites with high internal strain near the surface. If mechanisms of energy transfer from the concentrated optic phonon modes (with high amplitude and frequency) to the atoms captured in the sites with high internal strain is really existed [10], then such energy transfer can lead to effective acceleration of the light atoms captured in the sites of high internal strain (hydrogen, deuterium helium).

Figure 19 and Figure 20

Regardless of mechanisms involved in ECPE phenomenon in Pd and Ti, we emphasize that some peculiarities of LENR could be more clear, taking into account similarities between processes observed in electrolytic loading of these metals (LENR effects) and powerful laser irradiation effects. These similarities include:

-Neutron spectra for deuterated targets in laser and LENR experiments : besides 2.45 MeV peak high energy neutrons up to 10 MeV (compare: P.A. Norreys et al., Plasma Phys. Control. Fusion, **40**, 175(1998) and A.G. Lipson et al., Fusion Tech., **38**, 238 (2000)). High energy component of neutron spectra in laser case is explained by presence of MeV deuterons (Probably similar effect in LENR case).

-Charged particle emissions, including their energy ranges

-Isotope separations and exotic transmutations

-Production of craters at the target surface.

-Possible generation of isomeric states of nuclei in solids (after-emissions of gamma and X-rays)

158) An interesting article from MIT

Ludwik Kowalski (7/8/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Here is an interesting extract from an article about cold fusion published recently (April 23, 2004) in the MIT magazine "Technology Review:" The title of the article "Is Cold Fusion Heating Up?," and the introduction, indicate that it was prompted by the pending evaluation of cold fusion by DOE.

". . . The evidence for 'new physics' has been building for years, says Peter Hagelstein, associate professor of electrical engineering and computer science at MIT, who chaired the tenth International Conference on Cold Fusion in Cambridge last August. Experiments performed under properly controlled conditions reliably produce more heat than standard theory predicts. Nuclear products show up in about the right amounts to account for this excess heat. Patterns have emerged that explain previous anomalies. When Hagelstein saw how pieces of the puzzle were fitting together at the August meeting, he urged the Department of Energy to reconsider a field that had been cast out of orthodox science soon after its birth.

Over the past 15 years, enthusiasts have generated some 3,000 manuscripts on cold fusion, but very few were ever published in scientific journals. Many results evaporated under outside examination, and promoters pushed 'free energy' schemes that sounded more like perpetual motion than physics. Most of those manuscripts 'are not helpful,' says Hagelstein, a theorist with wide-ranging interests in optics, energy, and nuclear physics. But some 50 do show interesting, reproducible effects. 'The heat effect has been replicated many times,' Hagelstein. It works only when deuterium is loaded into palladium cells, and never when normal hydrogen is used instead of the heavy isotope. Exacting measurements with heat-measurement instruments have answered criticisms of the original experiments. Excess heat has been measured beyond what Hagelstein considers any reasonable doubt. Experiments that produce excess heat also have yielded helium-4, one potential product of the fusion of two deuterium nuclei, in amounts that correlate with the excess heat. Theory predicts that the fusion reaction should generate 24 million electron volts (MeV) of energy per helium-4 nucleus. An analysis by Michael McKubre of SRI International detected energy of 31 MeV— a match within the experimental uncertainty of plus or minus 13 MeV. Skeptics had doubted the reaction was possible, but Hagelstein says McKubre's analysis of the experiments, reported at last year's cold fusion meeting, shows that fusion of two deuterium to yield helium-4 'is not as nutty as it initially seemed.'

McKubre has also found that the seeming inconsistency in experimental heat production arose from differences in the amount of deuterium packed into the palladium electrode. Whenever the number of deuterium atoms loaded into the metal matched or exceeded the number of palladium atoms, excess heat was generated. Palladium loaded with slightly less deuterium produced inconsistent results, and if the deuterium level was reduced by a great amount, then no excess heat at all was produced. Deuterium loading was hard to control and limited by the strength of the metal. Unfortunately, palladium strength is difficult to predict or control, and is not improved by purification; indeed, the purest palladium ruptured at lower loadings, and the highest strength was seen only in one impure batch. ..... 159) From another review of cold fusion

Ludwik Kowalski (7/11/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Unlike my review of recent cold fusion claims (see unit #152) the paper presented by George Miley (1) was not prepared by an uncommitted outsider. George is the author of numerous research papers; as the editor of a scientific journal devoted to nuclear fusion he has been a leader of that field from the year in which the controversy started. Let me begin with an attempt to categorize cold fusion research. The first subdivision of the field is obvious: some research topics are nuclear while others are not. Research on emission of unexplained neutrons and protons (via counters of such particles), or research on changes in isotopic ratios, belong to the first category while research on the unexplained excess heat (via calorimetry) belongs to the second. Seminal work of Steven Jones was nuclear, seminal work of Fleischmann and Pons was not.

George Miley offers an interesting further categorization of nuclear topics. He divides them according to reactions that take place. The first subgroup consists of DD reactions while the second consists of so-called "lattice reactions." The DD reactions are:

D + D --> ^{3}H + p
D + D --> ^{3}He + n
D + D --> ^{4}He + g

The first two are named "normal DD fusion" (some people call it "hot fusion") while the last is named "P-F type Cold Fusion." The P-F stands for Pound and Fleischmann who speculated that excess heat might have nuclear origin.

The so-called "Lattice Reactions," on which Miley focuses in the review, are symbolically described as "p/D + metal." That means they are initiated by fusion of ^{1}H ions (or ^{2}H ions) with much heavier atomic nuclei in crystal lattices. These reactions are called transmutations. Collectively P-F Cold Fusion and Transmutations are referred to as LENR (Low Energy Nuclear Reactions).

There are two kinds of transmutations reactions, those in which compound nuclei are formed and those which are called "direct." That characterization of nuclear reactions is not new, it can be traced to late 1930s (Niels Bohr) and to numerous textbooks published in late 1940's. Formation of a compound nucleus is a process of complete fusion of two atomic nuclei followed by either fission (typically into two fragments) or emission of charged particles and neutrons. Direct reactions produce specific products, for example, transformation of ^{88}Sr into ^{96}Mo described by Iwamura (see item 152 on my web site). Compound nucleus reactions, on the other hand, result in a large number of products (see Figure 4 of Miley's review).

I think that this categorization of the cold fusion field can be useful. Let me make some comments.

1) The term "cold fusion" was used by Steven Jones long before Fleischmann and Pons offered a speculation that excess heat might have nuclear origin.

2) Rates at which emission of nuclear particles is observed in Jones' experiments

(typically one per hour or less) are too small to generate measurable excess heat.

3) According to Karabut (see item #13) alpha particles of 14 MeV are emitted when Pd is bombarded by ^{2}H ions of ~1keV in a glow discharge apparatus. Such rates are also too low to generate measurable excess heat.

4) Transmutations, on the other hand (according to Miley and others who observe them), take place at much higher rates, typically above 10^{11} reactions per second per cubic centimeter. This is illustrated in Figure 4 of Milley's review paper. Transmutation reactions have been studied in 14 separate laboratories, worldwide, as listed by Miley.

5) Accumulation of ^{4}He, reported by several excess heat researchers, worldwide, is also occurring at very high rates. Generation of heat at the rate of 1 W, for example, is associated with generation of about $3*10^{12}$ atoms of helium. In other words, production of each atom of helium (often called "an ash resulting from nuclear burning") is associated with the liberation of about 23 MeV of energy. That number is in very good agreement with generation of helium in thermonuclear reactions (sun and atom bomb). Let me end with a puzzling question about generation of helium: "why is it relatively rare in thermonuclear setups (one out of one million reactions in hot plasma) and dominant in some cold fusion setups?"

P.S.
According to Milley, "Excess heat production was also observed simultaneously with transmutations in various experiments..... The product production rate correlates with the excess power measured within the experimental accuracy." This is important because one of the most convincing argument against the reality of excess heat in cold fusion (in the 1989 DOE evaluation of that field) was the lack of evidence for the "commensurate reaction products." The excess energy claim was compared to fire without any byproducts of burning. If the reported accumulation of ^{4}He, and the accumulation of transmutation products, are real (not due to migration of impurities, or errors of measurements) then the 1989 argument is no longer valid. Will the upcoming DOE evaluation of cold fusion address this essential issue?

161) A set of messages about cold fusion

Ludwik Kowalski (7/20/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

This thread on PHYS-L, the Internet discussion list of physics teachers was triggered by this message from Teacher 1 (myself). Other contributors will be identified only as Teacher 2, Teacher 3, etc.

Teacher 1:
An interesting piece from Brian Josephson (Nobel prize in 1973 for the discovery of a superconducting electronic switch) about pseudoscience.

www.lindau-nobel.de/images/ock/media/downloads/Media_1703187544.htm

It is his lecture at the last annual meeting of Nobel winners in Landau, Germany. According to Haiko Lietz, a science reporter who attended the gathering: "the Lindau conference was very interesting, as one can imagine. Brian Josephson created a big stir. He spoke extensively on cold fusion, and how unscientific attitudes and a publication policy prohibited the field from becoming known in the scientific community. He was the talk of the day. Many students were asking him questions, they were open and interested. Reactions by the Nobel laureates were twofold: Some seemed to be surprised that cold fusion is still around, while others remained silent."

The immediate reply from Teacher 2 was:
"Earthshaking shaking claims require earthshaking evidence. Are you saying that such evidence is being suppressed and HAS been for lo these many years ??? This stand wouldn't be giving the 'physics community' much credit. Has EVERYONE missed out on the shaking of the earth? How long was required for 'polywater' to become a lost cause? or does that research continue as well?"

Referring to the above, Teacher 1 wrote:
"1) In my opinion dangers of degeneration of science are very real. And I have no doubt that pseudoscientists exist. But I see no evidence that major cold fusion claims, described in item #152 on my website: are examples of pseudoscience. Some of these claims might become part of accepted science, others might be rejected as invalid (due to errors etc.). That is normal.

2) Let me give you an example of what Brian Josephson calls the "denunciation mode" of operation (by leaders of intellectual activities, such as editors of our journals). The example is based on personal experience (see item #154 on the above website). An objective summary of major cold fusion claims (see item #152) was consecutively submitted to editors of five journals. The manuscript was rejected by all of them, without being sent to referees. Each editor answered differently but the bottom line was the same: your manuscript does not correspond to our current needs. My review, as you can verify, does not defend cold fusion claims; it tries to describe them objectively. Why isn't the review sent to referees? Why couldn't it be published, provided, of course, that its accuracy is not challenged by referees? This is not new; the intellectual establishment has often operated in the denunciation mode. How can critical thinkers be protected from bureaucrats? How do bureaucrats benefit from acts of suppression and oppression of cold fusion?

3) I just became a retired teacher and this allows me to participate in the 11th Cold Fusion Conference in France (October 31-November 5). It is very unlikely that my own research (just started) will produce something worth reporting. I do see something but it needs more attention. Therefore my presentation, during the public relations session,

will be based on what I wrote above. In that context your input, under this thread, will be highly appreciated. Or write to me in private, if you prefer.

4) In the message that started this thread I forgot to mention that I would not know about Josephson's lecture if Steven Krivit did not send me 'New Energy Times Newsletter' (dated July 15, 2004). Krivit, a journalist specializing in science, is the editor of that newsletter. To subscribe write to: newsletter@newenergytimes.com "

Shortly after the above was posted I received a private message from another teacher. It was a set of general observations about intellectual suppression.

Teacher 3 wrote: "Here's something you might find interesting.

COMPLAINTS ABOUT INTELLECTUAL SUPPRESSION ARE NOT "CONSPIRACY THEORIES.

Intellectual suppression in any community's publications certainly exists, since the beneficial purpose is "triage." Triage is there to prevent idiotic troublemakers from wasting our time. For example, if I submit rambling drunken poetry and nude photographs to the journal Nature, they will be discarded. That's intellectual suppression! And when we try to filter e-mail lists so spammers can't fill them with advertising, that's suppression of publication. Nothing wrong with it. And it's very, very common.

Inappropriate suppression also exists in the form of nasty back room politics, when for example the governmental/industrial leaders try to prevent whistle blowers from publicizing embarrassing mistakes and criminal acts. In other words, intellectual suppression often means the same as "coverup." Dr. Brian Martin maintains an entire website on the problems of political intellectual suppression in the sciences, see http://www.uow.edu.au/arts/sts/bmartin/

Intellectual suppression has a long history involving revolutionary science. Researchers who later created entire new fields of science discovered that they could not get their research published for years, often for decades. They eventually succeeded, but only after a major fight with suppression. No journal editors conspired to silence the revolutionary researchers. They simply assumed that their papers were misguided, or were outright crackpotism. Here's a small list:

Ridiculed, vindicated discoverers
http://amasci.com/weird/vindac.html

. . . There's no question that inappropriate intellectual suppression is a real problem, nor that appropriate suppression is essential.

In recent years I've noticed a strange group-think phenomenon among skeptical scientists. In online forums, crackpots start discussing topics like antigravity, perpetual motion, psychic phenomenon, etc., and they complain that science journals won't publish their research. The
crackpot's opponents then sneer, insisting that the crackpots complaints are nothing but a conspiracy theory.

Um. What? Let's get this straight. Someone wants physics journals to publish their papers where they prove Einstein was wrong... the papers are rejected everywhere... and if the crackpots complain about this, it means that the crackpots are CONSPIRACY THEORISTS? But... but... all the physics journals REALLY DO reject those papers. The crackpots really are being suppressed; their publications are being blocked from all legitimate journals (obviously with good reason.) I thought that the skeptics might be joking, but they're not. They really insist that anyone who complains about intellectual suppression is a conspiracy theorist who should be ignored.

Over the years I've found that this strange reasoning is very widespread among the online scientific community. I find it ridiculous, and I feel embarrassed when I try to point out the flaws to those making the argument. (And I feel very

confused when my observations are rejected, and the skeptics making these arguments continue to do so time and again.)

Just to make things perfectly clear once more: intellectual suppression is very real, and is a valid part of the science culture, so when an author complains of suppression, he/she is complaining about something genuine. Journal editors need not "conspire" together before rejecting my nude photographs, or rejecting papers about Bigfoot or UFO abductions or Cold Fusion. Those editors INDIVIDUALLY are disbelievers. That's why they reject the articles out of hand.

Here's something that may shed light on the proceedings. In marriage counseling I found out about a very common human foible: "Invalidation." If someone doesn't want to deal with their spouse's complaints, they can choose to "not hear" those complaints via the process of "invalidation," by declaring the complaints to be ingenuous (perhaps triggered by vengeance or other low motives.) Rather than taking the complaints seriously, the ears are blocked and the complainer is essentially silenced.

When a skeptic declares a crackpot's complaints to be "conspiracy theories", this is a clear example of invalidation: it's a psychological ploy whose most likely purpose is to excuse the skeptic from taking the crackpot's complaints seriously (or from even hearing them at all.) We need not even listen to conspiracy theorists, so declaring a noisy crackpot to be a conspiracy theorist gives us even more reason not to listen.

But when someone complains of suppression, their complaint is almost always genuine. And note well: they never complained about any conspiracy. It was the skeptic, the person supposedly in support of reason and rational argument, who put those words in the crackpot's mouth. Hmmm. Since this phenomenon is so common, perhaps it needs its own name. "Suppression complaints are conspiracy theories" is a bit wordy. Which class of logical fallacy does it fall under?

P.S. Here is a possible answer to the last question; it is pasted from:

http://www.nizkor.org/features/fallacies/straw-man.html

The Straw Man fallacy is committed when a person simply ignores a person's actual position and substitutes a distorted, exaggerated or misrepresented version of that position. This sort of "reasoning" has the following pattern:

1. Person A has position X.
2. Person B presents position Y (which is a distorted version of X).
3. Person B attacks position Y.
4. Therefore X is false/incorrect/flawed.

Teacher 1:
XX sent me a private message about dishonest skeptics (pasted below). I am responding to this message publicly because it deserves to be shared. Let me replace the term "skeptics" by "editors" and not use the term "theorists" to describe crackpots. In the context of this thread I am thinking about editors of journals who reject cold fusion manuscripts without sending them to referees. The bottom line, if I understand XX correctly, is that editors use negative labels to dehumanize crackpots in the eyes of the public . This allows editors to act with impunity. It might appear that editors conspire against crackpots but this is not true, they do this independently of each other because they individually believe that crackpots are not legitimate scientists. Editors, incorrectly, place cold fusion in the same category as astrology and UFOlogy. Is this a reasonable summary?

Decisions of what to accept and what to reject (without any further consideration) must be made by editors; that is part of their difficult job. A good editor, however, should be a critical thinker. Did five editors who rejected my paper think that I am a crackpot? Yes, I submitted a review of recent claims made by crackpots (see item #152 on my cold fusion website:

http://blake.montclair.edu/~kowalskil/cf/).

But I am not defending these claims; I am only describing them objectively.

[In the e-mail piece the message from Teacher 3 was pasted here]

Teacher 4:
Josephson apparently says there is something to telepathy as well. "Nobel laureate, Cambridge physicist Brian Josephson 'Yes, I think telepathy exists,' he told The
Observer, 'and I think quantum physics will help us understand its basic properties.' "

Teacher 1:
Josephson's speculative 1991 paper on telepathy can be read at his website:

http://www.tcm.phy.cam.ac.uk/~bdj10/

Should this paper disqualify him? I know very little about topics discussed by him. Also see:

http://www.tcm.phy.cam.ac.uk/~bdj10/stamps/today.html

A message from a friend:
After posting the above reply I received a private message from a friend who is not a teacher. In the first sentence he wrote: "I am convinced that cold fusion is our best hope for a pollution-free source of energy to sustain this planet."

Here is my reply:
Yes, many people believe in this. Same of them, when asked "what do you know about cold fusion?" reply in the same way. In my opinion, however, this is still "science fiction." The main issue today is to determine whether or not scientific claims made by leading cold fusion researchers are valid. That should be decided by a panel of experts recently appointed (?) by the DOE. In my opinion suggesting practical applications might be counterproductive, at this time. A panel, if asked to evaluate practical uses of unrecognized discoveries, would most likely produce a negative verdict. But a panel of honest experts asked to evaluate validity of major scientific claims, in the area of cold fusion, would probably produce a positive verdict. After all, new data supporting such claims are very strong. Will the DOE declare that cold fusion should no longer be treated as pseudoscience? It will depend on the panel's report. Such declaration will not happen unless the report is positive.

The two most important claims, as explained in item #152 at my website, are:

http://blake.montclair.edu/~kowalskil/cf/

a) Unexplained emission of charged particles and neutrons from metals loaded with deuterium.

b) Generation of excess heat associated with accumulation of helium at the rate of one atom per 23 MeV of heat energy.

I am selecting these two claims because they are supported by research of several groups in different countries. What is needed is a set of clear answers to the following three questions: (a) Were the authors of these claims qualified scientists? (b) Were their methods of validation scientific? (c) Was there any evidence of fraud?

On the basis of answers to these questions the panel might recommend that damaging labels, such "voodoo science, pseudoscince or fiasco of the century" should be declared invalid by the DOE. Elimination of such pejorative labels will most likely turn cold fusion into science able to defend itself against honest scientific criticism. Sooner or later that might lead to some kind of practical applications. It is possible that formally legitimized cold fusion research will eventually give us pollution-free sources of energy. But that is not at all obvious today. The situation might change dramatically after at least one cold fusion experiment becomes 100% reproducible (by competent scientists, of course), and after the underlying phenomena are understood.

Teacher 1:

According to Teacher 2, “Earthshaking claims require earthshaking evidence.” Brian Josephson also commented on this. He thinks that this dictum is too strong. It implies that critics of cold fusion are able reject new claims indefinitely, as explained at:

http://www.tcm.phy.cam.ac.uk/~bdj10/

I agree with Teacher 2, provided the “earth-shaking evidence” does not refer to something unreasonable or impossible. Instead of the “earthshaking evidence” I would say “very strong evidence.” A researcher in the area of cold fusion should consider all possible objections and address them, one after another. Fleischmann and Pons, for example, should have anticipated requests for the evidence that excess heat is nuclear before allowing the university to release the results of findings.

They should also have waited before the reproducibility dilemma were solved or understood. Allowing a press release to go ahead without a peer reviewed publication also weaken their case enormously. Such press release might have been appropriate in a well established area but not in an area known to raise many objections. One kind of experiment might be sufficient in a well established area, several kinds of experiments are necessary when new results are in conflict with what is already in our textbooks. Yes, I know that the situation at the University of Utah was very complex; as usual, things are much clearer in retrospect. In sum, a discovery challenging an accepted paradigm must be announced more carefully than a discovery which does not challenge it.

Responding to the above the friend referred to the straw man man fallacy used by opponents of cold fusion. (The insertion added below the message from Teacher 3 was inspired by his reply.)

The friend also wrote:
“. . . ANY scientist who is honest, open-minded, AND skeptical can look at the data and conclude that the Cold Fusion effect is AS REAL as any other new science is or was in its early stages. The DOE matter is sheer politics and money, but a spin-off from a positive vote will be extra incentive to private industry and hopefully, God-willing, a change in policy at the US Patent Office which is a major block to progress.” . . .

Teacher 1:
I am not sure which block (the editors who reject research papers without sending them to unbiased referees or clerks in our patent office) is more effective at this time.

Teacher 5: (another private message)
PATHOLOGICAL DISBELIEF (from today's UnderNews)

http://www.lindau-nobel.de/images/ock/media/downloads/Media_1703187544.htm

"Pathological Disbelief" was the title of a lecture by 1973 Nobel Prize winner Brian D. Josephson, who teaches physics at the University of Cambridge, delivered at the 2004 Lindau meeting of Nobel Laureates. It describes a problem for science but also one for journalism which has over the past few decades moved from ubiquitous skepticism to ubiquitous condemnation of skepticism, most popularly expressed in labeling the skeptic
a "conspiracy theorist."

Josephson, incidentally, cites the treatment of cold fusion as an example. Some readers may recall that the Review is one of a tiny number of publications that has treated research into cold fusion as newsworthy ? Not because this research will necessarily pan out but because the suppression of this research by both science and journalism violated the objective principles of both trades.]

BRIAN D. JOSEPHSON - This talk mirrors "Pathological Science", a lecture given by Chemistry Laureate Irving Langmuir. Langmuir discussed cases where scientists, on the basis of invalid processes, claimed the validity of phenomena that were unreal. My interest is in the counter-pathology involving cases where phenomena that are almost certainly real are rejected by the scientific community, for reasons that are just as invalid as those of the cases described by Langmuir.

Alfred Wegener's continental drift proposal provides a good example, being simply dismissed by most scientists at the time, despite the overwhelming evidence in its favour. In such situations incredulity, expressed strongly by the disbelievers, frequently takes over: no longer is the question that of the truth or falsity of the claims; instead, the agenda centers on denunciation of the claims. . . In this "denunciation mode", the usual scientific care is absent; pseudo-arguments often take the place of
scientific ones. . .

Other popular forms of attack are "if X were true we would have to start over again" (as we of course had to do with relativity and quantum theory, and so the argument proves nothing), and then there is the dictum "extraordinary claims require extraordinary evidence", which has the marvelous feature of allowing the requirements for acceptable proof to be stretched indefinitely as more and more support for a contested claim comes in. Its originator, the late Marcello Truzzi, later decided that his comment was 'a non sequitur, meaningless and question-begging', and had planned to write a debunking of his own creation.

"Cold fusion" appears to be the modern equivalent to continental drift, starting with the controversial claim, made by Pons and Fleischmann in 1989, to have generated in an electrochemical cell heat considerably in excess of anything explicable in conventional terms. This provoked hostile reaction: ignoring the possibility that an aggregate of ions in a condensed matter matrix may behave differently to a collection of freely moving ones, it was asserted that nuclear fusion could not be responsible for the claimed excess heat.

Then came 'failure to replicate' by a number of groups, equated with the non-existence of the phenomenon, ignoring the fact that if different groups get different results there can be two explanations, one that the people who see some effects are bad experimenters, and the other that they were in fact better at creating the precise conditions needed for an effect to be seen.

Usually in such cases time tells which side is right, but here the steadily mounting evidence that there was a real effect was suppressed through the publication policies of the major journals. Consequently, these apparently supportive results are not known to most scientists, who simply take it for granted that the Pons-Fleischmann claims have been disproved.

In an attempt to promote proper discussion of the issue, I tried in 2002 to upload a survey by Storms to the preprint server arxiv.org, the natural place for facilitating such discussion, but the moderators frustrated this intent by deleting the review, declaring it "inappropriate" (chemists, being a more robust species than physicists, were permitted to see it on their own server chemweb.com).

A breath of fresh air has been introduced into the situation now, with the recent decision of the US Department of Energy to review the research; if the reviewers simply look at some of the research going on they will almost inevitably conclude that fusion can take place at ordinary temperatures, with a yield far in excess of the 'almost undetectable level' referred to in Langmuir's lecture.

The overall situation seems profoundly unsatisfactory. The system built up over the years to promote scientific advance has become one that narrow-minded people can use to block any advance that they deem unacceptable. This demands urgent review: otherwise, just as astronomy became fixated on the reasonably accurate, but wrong, Ptolemaic model, science will become fixated in a respectable, but inaccurate, view of reality.

Teacher 1:
1) Let me observe that Teacher 5, who is usually very vocal on the Phys-L list, preferred not to share personal thoughts. He quotes the UnderNews, he quotes the summary of Josephson’s lecture. I am not surprised; most physics teachers are likely to be undecided. They are open-minded people but the flow of information about cold fusion is not normal. Many of them are old enough to remember the 1989 euphoria and their opinion on the subject was formed at that time. I was also convinced, until about two years ago, that cold fusion claims should be rejected.

2) In reading the quoted summary of the lecture again I notice that Josephson refers to Marcello Truzzi, the originator of the "extraordinary claims require extraordinary evidence" phrase. Who was this man? According to the website devoted

to him Truzzi made “contributions to sociology, the history of juggling, magic, and the study of the paranormal.” Aha, study of the paranormal again! Should cold fusion still be considered paranormal or should this label be applied to the “suppression of research [in a targeted field] by both science and journalism”?

3) I find it interesting that Josephson, who is not a cold fusion researcher, refers to “the possibility that . . .nuclear fusion could not be responsible for the claimed excess heat.” He probably thinks that what is observed in “an aggregate of ions in a condensed matter matrix” might be very different from what is known to occur in hot plasma. Wasn’t this also the main observation made by J. Schwinger, another theoretically inclined Nobel Laureate who was trying to make sense out of cold fusion? Are they referring to the lowering of the Coulomb barrier in condensed matter, for example, via some kind of screening effect? That is what Steven Jones thinks, according to his papers at the last cold fusion conference (see item # 113 at my cold fusion website). Some theoretical papers presented at the conference also addressed this topic.

Teacher 1:
Guess what? Messages from this thread, plus additional comments, became unit #161 on my website. See it at:

http://blake.montclair.edu/~kowalskil/cf/161josephson.html

I might append other messages and comments later, if they materialize.Share what is worth thinking about cold fusion social issues, about its scientific aspects and, above all, what should we tell students about the controversial cold fusion topics? I suspect that questions of that nature will be asked this fall, after the DOE review process is completed.

During my retirement party I gave a short description of current cold fusion claims. It was based on unit #152 on my website. I also mentioned that I might become a cold fusion researcher. The audience consisted of faculty and some students. Recently I was contacted by a student who was present, not one of my students. In an e-mail message she introduced herself and asked if she could assist me in this research. We met several days later and I tried to discourage her. This will not help you professionally, I said. On the contrary, this can hurt you. Many will think that you are a crackpot, like those who take astrology or UFO seriously. Finding financial support for such research is likely to be impossible (I am going to pay for the necessary expenses from my own pocket). Read about the unhealthy situation at my website and think again. I will not be disappointed if you change your mind. About a week later I received this reply:

"I wanted to inform you that I have carefully thought about the pros and cons and I feel that working with you would be very beneficial to me. Hopefully you will allow me to assist you in the fall."

Do I have a moral right to take advantage of this offer? She is a sophomore with excellent grades, majoring in both physics and chemistry.

Teacher 3 (in private again):
In order to convince her that very severe career-damage is guaranteed, you could write up a simple contract where she promises to keep her involvement in this a secret from anyone in the science biz (and keep the stuff OFF her resume, especially off her grad-school application.)

Cold fusion suppression is a conspiracy theory? Yeah, suuuure. Just let any non-tenured faculty try seriously performing some CF experiments, and see how fast they're booted out of a job. With suppression at such a high level, and with so-called "Skeptics" ready to start back-room proceedings against anyone who doesn't toe the line re. conventional physics, only retired physicists and physics-hobbyists can risk working in the field. And that's really shameful. What does it say about the physics community? It says that the equivalent of bicycle-shop owners will make the breakthrough if there are any breakthroughs to be made. (Or perhaps like the situation with Robert Goddard, it will be some 3rd World dictator who will do the equivalent of dropping heretical impossible ICBMs on London in 1944.)

Remember that J. OM. Bockris of Texas A & M, who literally wrote the book on electrochemistry, published some CF/transmutation papers and was attacked by colleagues who circulated a secret petition to get him kicked out of the university. Even with his enormous academic stature he almost didn't make it. It's my belief that he was saved only

because he was on the verge of retirement, and for that reason the group trying to remove him didn't have the resolve.

Teacher 5:
She's an adult, correct? She's had full disclosure, right? She's an undergrad. where few, if any, do research assisting? She may chose to report this work or not, where non-reporting won't signal anything? She may stop anytime or continue till graduation or beyond?

Teacher 6:
Over the weekend I attended a conference on teaching non-majors introductory astronomy classes. In passing, one of the speakers asked, "How do we handle alternative theories and gaps in our understanding of the universe?" This (and the cold fusion thread) caused me to wonder: At what point is it appropriate to bring up theories that are hard to handle, are probably wrong but may be true, and just aren't mature?

Specific Problems:

*Should MOND[Modified Newtonian Mechanics] ever be discussed? I have seen a grad student burned at the stake for giving a journal review talk on MOND, and I've also seen a leading astronomer with his face in his hands worried that MOND may have some validity. I usually rely on Greg Bothun's site: < http://zebu.uoregon.edu/special/mond.html > What do you do?

*How do you answer the question: "What was there before the Big Bang?" I typically say, "Here be dragons" and use magazine articles and popular books to discuss some of the theories. Do you have problems with religion creeping into your classroom with this topic?

*How many dimensions do you say the universe has? *Are string theory or super symmetric particles mentioned? I know I don't have more than a very surface understanding of these topics. What should/can we hope for our students to understand? Is this best taught as a "Why we should spend money to build accelerators and bury detectors?" and then test their knowledge of FERMI and CERN, and Super Kamiokande?

*Does Cold Fusion come up when you discuss nuclear energy? *What other discussions are best dropped or skirted around? . . .

Teacher 7:
. . . New, and especially controversial or speculative, developments almost never need to be discussed in a text. If it is appropriate, the instructors can bring them up in class (this assumes that the instructors are keeping up with the subjects they are teaching).

Teacher 8:
. . . [Students should] be exposed to the idea that scientists and educated people could be biased such as Galileo's detractors who refused to look through a telescope because the "images were not real". Or consider how Einstein persisted in raising objections to QM, how Boltzmann committed suicide before his theory became scientific canon, or how MDs continued to wear bloodstained wool coats long after there was clear evidence for antiseptic operating conditions. Paradigm change takes time. . . .

Teacher 1:
I often see the term paradigm in connection with cold fusion. But I am not ay all convinced that the validation of experimental cold fusion facts would lead to a change of paradigm. Why should one take it for granted that the existing paradigm can not possibly accommodate theoretical models of cold fusion phenomena? Discovery of nuclear fission (in 1939), as far as I know, did not make the liquid model of nuclear reactions invalid. Fission of uranium, after being recognized, was at once explained in terms of this model. Who knows what will happen, and how soon, after the experimental cold fusion claims are recognized as valid by the mainstream scientific community.

Here are some well known details. The paper of Hahn and Strassmann, announcing the discovery of fission, contained an interesting phrase “it makes no sense to us.” Hahn was referring to strange transmutations, such as production of

barium. The explanation, first by Lise Meitner and then by Niels Bohr, appeared about one year later. It was based on the liquid drop model that was used since 1936 to make sense of nuclear reactions.

Teacher 1:
After posting the above I found (on the Internet) the following abstract of a paper in the Czechoslovak Journal of Physics (**49** (6): 985-992, June 1999). The author is **Xing Z. Li** (*Department of Physics, Tsinghua University, Beijing 100084, China) and the title is: "***Overcoming of the Gamow tunneling insufficiencies by maximizing the damp-matching resonant tunneling."** This does not sound like a suggestion for a departure from Gamow's theory of tunneling; it sounds like an attempt to use it creatively. But my knowledge of the theoretical physics is very limited. Perhaps somebody will write a summary of current attempts "to make sense of cold fusion data" for introductory physics teachers. That could become a very useful item on my website.

"The resonant quantum tunneling current through the barrier between two wells may be maximized when the damp (absorption) in one well matches the barrier parameters. The maximum resonant tunneling current is much greater than the conventional expectation by a factor of 1/TET^2 (1/TET^2 is the Gamow tunneling factor). It is shown that with all the established quantum mechanics, very much higher reaction probabilities between nuclei in contrary to the Gamow theory can be explained in agreement with experiments. Particularly, the resonance will select the sub-barrier fusion with a suitable fusion rate which matches the barrier parameters. This selective resonant tunneling model is able to explain both the hot fusion data (e.g. the width of resonance in 11B(p, alpha)2alphas reaction) and the cold fusion data (e.g. "excess heat" without any commensurate neutron and gamma."

Teacher 9:
Way back at the beginning of this thread, Teacher 6 asked a two-part question: "How do we handle alternative theories and gaps in our understanding of the universe?" And mostly "alternative theories" is a codeword for crackpot theories ... but I would like to nudge the discussion toward the second part of the question: IMHO there ought to be more discussion of non-crackpot unanswered questions. Lists of important open questions in physics are easy to find. One of my favorites is John Baez's list

* * * * <http://math.ucr.edu/home/baez/physics/General/open_questions.html>

Another is David Mermin's list of "alternate" questions to ask a visitor from the future:

* * * * <http://www.qub.ac.uk/mp/questions/alternate.html>

Naturally you can find lots of other lists:

* * * * < http://www.google.com/search?q=important+open-problems+physics>

and it is also interesting to look at the open problems
in allied fields (math, computing, fluid dynamics, ...)

Also in this context I suppose one is obliged to mention "Physics in a New Era" .... the view from the National Academy:

* * * * <http://www.nap.edu/openbook/0309073421/html/>

but I find it to have more detail than imagination. Tangential remark: There is a whole lot of good physics and math stuff on Baez's site:

* * * * <http://math.ucr.edu/home/baez/>

Well worth exploring.

Teacher 1:
The observation about , "a codeword for crackpot theories," is likely to be correct; especially when such theories are

developed by obscure people publishing in obscure journals. Credentials and professional associations do not guarantee anything but they should be looked upon very seriously when it comes to alternative theories, or earth-shaking experimental data.

I believe that exposing crackpot theories is a worthwhile exercise, provided one is knowledgeable enough. In exploring the Internet I often encounter claims that there is free energy from torsion fields. That is far above my head, as far as mathematics is concerned. But I will address this topic in the next unit.

162) Torsion effect: does it explain cold fusion?

Ludwik Kowalski (7/23/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

In searching for cold-fusion-related topics I often encounter claims about “torsion field” and about “excess energy from vacuum.” The term “zero-point energy” is often used in this context, as one can check by browsing the Internet. An e-mail message from China, received on July 16, made me think about this topic again. The author wrote:

Dear Dr. Kowalski:
. . . A model called "Vortex Dynamics" is proposed by us to give an explanation for cold fusion. This model was mentioned by Thomas Dolan, IAEA Officer(1995-2001) for fusion in his speech as five majoring models for CF mechanism, in the summary session at ICCF-9, Tsinghua Univ. May,2002, Beijing. I would like to introduce this model to you for your reference. Thank you for your attention, and awaiting your comments. With best regards.

Prof. Xingliu Jiang, Physics Department of
Bejing University of Aeron. and Astron.
jiangxl@buaa.edu.cn

==========

The attached file (shown at the end of this unit) did not convince me that the authors found an “explanation of cold fusion.” The impression was the opposite; it added to confusion in my mind. What do Zero-Point Energy and Vortex Dynamics speculations have to do with cold fusion? Did they develop a “theory of everything?” Can that theory be used to “explain” burning of wood, reality of quarks and the assassination of Julius Caesar? I did not reply because I do not like to express opinion about topics belonging to unfamiliar areas of physics. My reaction to Zero-Point Energy claims (seen on the Internet) and to Hydrinos (explained in an earlier unit) are essentially the same -- wait till somebody else helps me to accept them.

This unit was prompted by the ongoing thread on Phys-L, an Internet list for physics teachers. The name of the thread is “Teaching science on the edge of knowledge.” An astronomy teacher asked: “How do we handle alternative theories and gaps in our understanding of the universe?” A physics teacher responded “mostly ‘alternative theories’ is a codeword for crackpot.” Then he elaborated on “the gaps in our understanding.” In doing this he made a reference to John Baez's website:

http://math.ucr.edu/home/baez/physics/General/open_questions.html

At that site (see http://math.ucr.edu/home/baez/vacuum.html) I found the following description. How does the Vortex Dynamics theory of Xing-liu Jiang differ from the topic described by Baez? Unable to answer this question let me turn to what Baez wrote about the energy of the vacuum.

What's the Energy Density of the Vacuum?

John Baez

August 25, 1999

People talk a lot about "vacuum energy" or "zero-point energy" - that is, the energy density of empty space. In cosmology, people also call this quantity the "cosmological constant", or "dark energy". Sometimes kooky people get really excited about the idea that if we could only *use* this energy somehow, all our problems would be solved. But first things first! Does this energy really exist? And if so, how much of it is there?

Once upon a time, someone named Amw wrote:

>I have heard widely varying numbers for so called "zero point
>energy", some as low as practically zero and some as high as
>astronomical. It gets to the point I am not sure what to think.

To which I replied:

Yes, one hears lots of conflicting stuff about this. However, you've come to the right place to get to the bottom of it all.

Here's the deal. We have two fundamental theories of physics: quantum field theory and general relativity. Quantum field theory takes quantum mechanics and special relativity into account, and it's a great theory of all the forces and particles *except* gravity, but it ignores gravity. General relativity is a great theory of gravity, but it ignores quantum mechanics. Nobody knows how to reconcile these theories yet. That's what people working on "quantum gravity" are trying to do.

Now, the reason I'm telling you this is that quantum field theory and general relativity have really different attitudes towards the energy density of the vacuum. The reason is that quantum field theory only cares about energy *differences*. If you can only measure energy differences, you can't determine the energy density of the vacuum - it's just a matter of convention. As far as we know, you can only determine the energy density of the vacuum by experiments that involve general relativity - namely, by measuring the curvature of spacetime.

So, when you ask about the energy density of the vacuum, you get different answers, depending on whether the person answering you is basing their answer on general relativity or quantum field theory. Let me run through the 5 most common answers, explaining how people reach these different answers:

1. We can *measure* the energy density of the vacuum through astronomical observations that determine the curvature of spacetime. These measurements say the energy density is VERY CLOSE TO ZERO. We're not really sure if it's positive, negative or zero. Some recent observations suggest that it's positive, but this is not yet certain. All we really know is an upper bound: in terms of mass density, its absolute value is less than 10-29 grams per cubic centimeter. In terms of energy density, this is about 10-9 joules per cubic meter.

To believe these measurements are right, one must have some faith in general relativity, because that's the theory which we use to relate spacetime curvature to energy density. The more accurate measurements attempt to determine an actual *value* for the energy density of spacetime, or at least its *sign*. These require more faith in general relativity, and also other assumptions about cosmology. However, the basic fact that the energy density of spacetime is very close to zero is almost inarguable: for it to be false, general relativity would have to be *very* wrong.

2. We can try to *calculate* the energy density of the vacuum using quantum field theory. If we calculate the lowest possible energy of a harmonic oscillator, we get a bigger answer when we use quantum mechanics than when we use

classical mechanics. The difference is called the "zero-point energy". The zero-point energy of a harmonic oscillator is 1/2 Planck's constant times its frequency. Naively we can try calculating the energy density of the vacuum by simply summing up the zero-point energies of all the vibrational modes of the quantum fields we are considering (e.g. the electromagnetic field and various other fields for other forces and particles). Vibrational modes with shorter wavelengths have higher frequencies and contribute more vacuum energy density. If we assume spacetime is a continuum, we have modes with arbitrarily short wavelengths, so we get INFINITY as the vacuum energy density. But there are problems with this calculation....

3. A slightly less naive way to calculate the vacuum energy in quantum field theory is to admit that we don't know spacetime is a continuum, and only sum the zero-point energies for vibrational modes having wavelengths bigger than, say, the Planck length (about 10-35 meters). This gives an ENORMOUS BUT FINITE vacuum energy density: about 1093 grams per cubic centimeter! But there are problems with this calculation, too....

One problem is that treating the vibrational modes of our fields as harmonic oscillators is only valid for "free field theories" - those in which there are no *interactions* between modes. This is not physically realistic. However, while taking interactions into account changes the precise answer, we are still left with an enormous energy density. And there's an even bigger problem, too....

4. Quantum field theory as it is ordinarily done ignores gravity. But as long as one is ignoring gravity, one can add any constant to ones definition of energy density without changing the predictions for anything you can experimentally measure. The reason is that without measuring the curvature of spacetime, one can only measure energy *differences*. The big problem with calculations 2 and 3 is that they ignore this fact. If we take advantage of this fact we are free to redefine energy density by subtracting off the zero-point energy, leaving an energy density of ZERO. In fact this is what is ordinarily done in quantum field theory.

5. An even less naive way to think about the vacuum energy density in quantum field theory is the following. In quantum field theory we are neglecting gravity. This means we are free to add any constant whatsoever to our definition of energy density. As long as we are free to do this, we can't really say what the vacuum energy density "really is". In other words, if we only consider quantum field theory and not general relativity, the vacuum energy density is NOT DETERMINED.

So, I've given you 5 answers to the same question:

1. VERY CLOSE TO ZERO
2. INFINITY
3. ENORMOUS BUT FINITE
4. ZERO
5. NOT DETERMINED

Which should you believe? I believe 1) because it is based on experiment and fairly conservative assumptions about general relativity and astronomy. Answers 2)-4) are based on somewhat naive theoretical calculations. Answer 5) is the best that quantum field theory can do right now. Reconciling answers 1) and 5) is one of the big tasks of any good theory of quantum gravity.

The moral is: for a question like this, you need to know not just the answer but also *the assumptions and reasoning that went into the answer*. Otherwise you can't make sense of why different people give different answers. For more on the zero-point energy of the harmonic oscillator try this and this. These require more mathematical sophistication.

==========

What follows is a description the dark energy found on the Internet. It is an interesting but I see no refernce to cold fusion in it. Is dark energy the same thing as zero-point energy of vacuum? It seems to be the same. The author is a

theretical astrophysicist; his paper has been published in June of 2004. It was published in a very prestigeous journal, Physical Review Letters (Phys.rev.Lett. 93 92004) 011301). The paper can be downloaded from:

http://arxiv.org/abs/astro-ph/0402316

Unfortunately, the best I can do is to read sentences between equations. That is not a critical comment; Salisury is addressing other experts.

Dark matter and dark energy may be different aspects of a single unknown force

In the last few decades, scientists have discovered that there is a lot more to the universe than meets the eye: the cosmos appears to be filled with not just one, but two invisible constituents –dark matter and dark energy – whose existence has been proposed based solely on their gravitational effects on ordinary matter and energy.

Now, theoretical physicist Robert J. Scherrer has come up with a model that could cut the mystery in half by explaining dark matter and dark energy as two aspects of a single unknown force. His model is described in a paper titled "Purely Kinetic k Essence as Unified Dark Matter" published online by Physical Review Letters on June 30 and available online at http://arxiv.org/abs/astro-ph/0402316 .

"One way to think of this is that the universe is filled with an invisible fluid that exerts pressure on ordinary matter and changes the way that the universe expands," says the professor of physics at Vanderbilt University.

According to Scherrer, his model is extremely simple and avoids the major problems that have characterized previous efforts to unify dark matter and dark energy.

In the 1970's, astrophysicists postulated the existence of invisible particles called dark matter in order to explain the motion of galaxies. Based on these observations, they estimate that there must be about 10 times as much dark matter in the universe as ordinary matter. One possible explanation for dark matter is that it is made up of a new type of particle – dubbed Weakly Interacting Massive Particles, or WIMPs) – that don't emit light and barely interact with ordinary matter. A number of experiments are searching for evidence of these particles.

As if that weren't enough, in the 1990's along came dark energy, which produces a repulsive force that appears to be ripping the universe apart. Scientists invoked dark energy to explain the surprise discovery that the rate at which the universe is expanding is not slowing, as most cosmologists had thought, but is accelerating instead. According to the latest estimates, dark energy makes up 75 percent of the universe and dark matter accounts for another 23 percent, leaving ordinary matter and energy with a distinctly minority role of only 2 percent.

Scherrer's unifying idea is an exotic form of energy with well-defined but complicated properties called a scalar field. In this context, a field is a physical quantity possessing energy and pressure that is spread throughout space. Cosmologists first invoked scalar fields to explain cosmic inflation, a period shortly after the Big Bang when the universe appears to have undergone an episode of hyper-expansion, inflating billions upon billions of times in less than a second.

Specifically, Scherrer uses a second-generation scalar field, known as k-essence, in his model. K-essence fields have been advanced by Paul Steinhardt at Princeton University and others as an explanation for dark energy, but Scherrer is the first to point out that one simple type of k-essence field can also produce the effects attributed to dark matter.

Scientists differentiate between dark matter and dark energy because they seem to behave differently. Dark matter appears to have mass and to form giant clumps. In fact, cosmologists calculate that the gravitational attraction of these clumps played a key role in causing ordinary matter to form galaxies. Dark energy, by contrast, appears to be massless and spread uniformly throughout space where it acts as a kind of anti-gravity, a repulsive force that is pushing the universe apart.

K-essence fields can change their behavior over time. When investigating a very simple type of k-essence field – one in which potential energy is a constant – Scherrer discovered that as the field evolves it passes through a phase where it can clump and mimic the effect of invisible particles, followed by a phase when it spreads uniformly throughout space and takes on the characteristics of dark energy.

"The model naturally evolves into a state where it looks like dark matter for a while and then it looks like dark energy," Scherrer says. "When I realized this, I thought, 'This is compelling, let's see what we can do with it.'"

When he examined the model in more detail, Scherrer found that it avoids many of the problems that have plagued previous theories that attempt to unify dark matter and dark energy.

The earliest model for dark energy was made by modifying the general theory of relativity to include a term called the cosmological constant. This was a term that Einstein originally included to balance the force of gravity in order to form a static universe. But he dropped the constant cheerfully when astronomical observations of the day found it was not needed. Recent models reintroducing the cosmological constant do a good job of reproducing the effects of dark energy, but do not explain dark matter.

One attempt to unify dark matter and dark energy, called the Chaplygin gas model, is based on work by a Russian physicist in the 1930's. It produces an initial dark-matter-like stage followed by a dark-energy-like evolution, but it has trouble explaining the process of galaxy formation.

Scherrer's formulation has some similarities to a unified theory proposed earlier this year by Nima Arkani-Hamed at Harvard University and his colleagues, who attempt to explain dark matter and dark energy as arising from the behavior of an invisible and omnipresent fluid that they call a "ghost condensate."

Although Scherrer's model has a number of positive features, it also has some drawbacks. For one thing, it requires some extreme "fine-tuning" to work. The physicist also cautions that more study will be required to determine if the model's behavior is consistent with other observations. In addition, it cannot answer the coincidence problem: Why we live at the only time in the history of the universe when the densities calculated for dark matter and dark energy are comparable. Scientists are suspicious of this because it suggests that there is something special about the present era.

==========

What follows is an example of another difficult to accept claim. The quoted fragment was found in an article published at:

http://antigravitypower.tripod.com/FreeEnergy/

“Independent inventors have put together electrical generators based mostly on the rotating magnet concept. What is highly interesting is that their experimental data is showing efficiencies exceeding 100 percent, and some show output energy exceeding input energy by a factor of two or more times ! These machines are known as 'Free-Energy' generators.

Nobody is quite sure just where this excess energy is coming from, but theories abound from the idea that this is a safe, radiation-free conversion of nuclear forces directly into electrical energy, to the concept that this type of device taps the so-called 'zero-point-energy' of the space-fabric itself.”

What is the evidence that zero-point energy contributs to the operation of motors based on rotating magnets?

I. INTRODUCTION

Many laboratories in world have observed nuclear reactions and excess heat in electrochemical systems. The mechanism of such anomalous phenomena is not being well understood according to normally accepted physics. Nuclear products with high concentration and tracks with highly collimated lines of low energy nuclear reactions in the electrochemical systems were recorded by CR-39 solid detectors and films at our laboratory [1,2]. These facts suggest that quasar model with spiral structure and extremely high enrage cosmic rays in the center could be used for explanation of the mechanism. It is supposed to use the concept of torsion field to interpret the observed phenomena, typically, the properties of axial acceleration, memory effect, and the polarized nuclear reactions with torsion effect [3].

II. PHENOMENA IN NATURE AND AT LABORLATORIES

The vortex and spiral structures are the archetype that appears at all levels of nature and laboratories, for example, atom structure, vortex lattice in superconductors, dense plasma focus, lightning, quasar etc. Recent report of dark matter annihilation at the galactic center describes that the cold dark matter near the galactic center is accreted by the central black hole into a dense spike [4]. Particle dark matter annihilation makes the spike to be a compact source of photons, electrons, positrons, protons, antiprotons, and neutrinos. It remind us for that there is a similarity among pitting corrosion with electrochemical noise, laboratory plasma pinching (dense plasma focus, for example), fast laser induced ion beams[5],and quasar spiral model with high-energy cosmic rays in spiral center in spite of large dimension difference.

Comparing the experimental results of electrochemical cells with excess heat and nuclear transmutation to astrophysics phenomena, it is supposed that the investigation of vortex dynamics of torsion coherence with the zero-point energy is essential for tapping the zeropoint energy. As it is predicted by quantum mechanics that the vacuum is seething with active energy, even at temperature of zero point Kelvin. This zero-point energy (ZPE) can be thought as an infinite number of virtual photons that popping out of the vacuum and going back in, but should a measurable effect en masse. To exam the origin of ZPE background, the interaction of matter with the ZPE can be treated on the basis of charged point particles interaction with a background of electromagnetic zero-point radiation with spectral-energy density.

Based on observation in the experiments, the following features are considered in order to understand the experimental results with electrical discharge systems.

A. ELECTROCHEMICAL DOUBLE LAYER

In an electrolytic cell, the electrolysis with high conductivity and the electrochemical double layer with large layer-capacitance lead to a typical structure of the cathode potential distribution similar to the cathode drop of glow discharge in low gas pressure. For a compact layer the thickness of the double layer is equal to one ionic layer, across which there is a linear fall of potential. Thus, high electric field exists in some regions on the surface of the cathode. The local

enhancement of the electric field on the cathode surface with the double layer is related to the protrusions and cracks similar to the tip discharge in air or in a vacuum. The current distribution depends strongly on the surface roughness and the work function of the electron emission. A high transient current density (> 10^8 A/cm^2) could be expected due to enhanced field.

B. ENERGY CONCENTRATION

On the cathode surface, the high persistent electrical fields (>10^7 V/cm) and large equivalent capacitance (>250μF/cm^2) lead to a high energy concentration in the double layer [6]. The concentrated field on the tips of the protrusions or cracks after a longloading period with deuterium on the palladium cathode surface creates a high transient electron flux because of the large distributed capacitance and the negligible inductance in a localized discharge mini-network. The experimental data show that the reactions take place only in some restricted areas that have specific properties. The idea of micro fusion due to the results of energy concentration and the high deuteron flux could be used to explain the nuclear transmutation.

C. TORSION FIELD AND THEIR EXPERIMENTAL MANIFESTATIONS

Elementary particles have the moment of quantity of motion, i.e. spin. If in any substance the spins of particle have a preferable direction, then is interpreted as spin polarization of the substance. Every substance creates a torsion-field (or called spin-field or axion field) in the space surrounding it when polarized by spins [7]. The superposition of torsion field, generated by the atomic and nuclear spins of each molecule, determines the intensity of torsion field in the space surrounding each molecule. Torsion field has strong penetration ability and does not interact with the crystal lattice of substances. The torsion field created by rotation of some sort of matter is concentrated in two opposite beams propagating along the rotation axis. The intensity of torsion-field with some lower constant value can be retained for several weeks after the rotation is stopped. Such the property of vortex mater has been observed recently in type II superconductors with magnetic flux line lattice [8]. The studies of vortex matter of type II superconductors have shown a number puzzling phenomena associated with vortex motion, including: lowfrequency noise and slow voltage oscillations; a history-dependent dynamic response, and memory of the direction, amplitude duration and frequency of the previously applied current.

Some behaviors of the torsion-field effect have been observed in the experiments of electrolysis regarding to so-called cold fusion, such as the gas bubble chains come out from the protrusions of the cathode surface for long time after switching off the electrolysis potential. The more surprising thing is the heat after death, which has been recorded by many labs. This phenomenon could be explained by the persistence effect of torsion-field produced by vortex dynamics of tip effect.

D. EXPERIMENTAL RESULTS IN THE ELECTROCHEMICAL CELL

CR-39 plastic films possessing with a high degree of optical clarity and isotope in track response, and been sensitive to neutron, proton,

tritium, alpha, and other charged particles, were used to detect the products of nuclear reactions. The films of CR-39 were immersed in the NaOH electrolyte of heavy water and placed adjacent to the tips of the cathode [9]. [The rest of this section is skipped. It contains figures which are not at all convincing. L.K.]

E. SONOLUMINESCENCE AND ?BUBBLE NUCLEAR FUSION?

Some scientists of Oak Ridge National Laboratory in America reported their articles of bubbles experiments in Science. Experimental results show that the radiation lights of sonoluminescence possess three characters: short duration with picoseconds; wide continual spectrum; highly oriented thin beams. Based on those characters, vortex dynamics with axial acceleration of bubble collapse could be inferred. [The rest of this section is skipped. L.K.]

III. CONCLUSION

Researchers of new energy study of ?cold fusion? type should pay great attention to the general processes of electrolysis to find the key points, which could play major role in the transit form the electrochemical processes to processes of torsion and the nuclear processes. From the authors? point of view, the evolution of double layers is of importance to understand the anomalous effect, typically on the protrusions of cathode. The change of space-time near the tips due to torsion field generated is expected to delivery the zero-point energy, and dynamic Casimir effect for the evolution of gas bubbles on the tips are expected to generate photons and excess heat [1].

The yields of transmutation products are related to the current distribution on the cathode surface. The cathodes of thin wire were benefit to the generation of nuclear reactions and excess heat for electrochemical systems. Careful examination of the evolution of electrochemical double layer will lead to a good understanding of pitting corrosion with electrochemical noise, and further to recognize the anomalous excess heat and nuclear reactions. Heat after death was observed in many laboratories. It is believed that the persistence behaviors of torsion field could be used to explain such anomalous phenomena. The contact between beads coated with a thin metallic layer or multilayered film and palladium black particles could be regarded as point-contact similar to the tip-effect [13]. We may say that, it is expected to reveal the puzzles of the mechanisms of high-Tc superconductivity with pinning vortices by torsion field theory [14,15].

163) On reproducibility of cold fusion experiments

Ludwik Kowalski (7/26/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

1) According to a very recent article (2004), in the online encyclopedia (Word IQ):

http://www.wordiq.com/definition/Cold_fusion

"In the best experimental set-up, excess heat was observed in 50% of the experiment reproductions. Various fusion ashes and transmutations were observed by some scientists."

Most people know that random guessing, when someone is trying to predict one of two equally probable outcomes, should result in 50% of correct predictions. In other words they know that, in such situations, the ability to predict 50% of outcomes does not demonstrate that the instrument of prediction is reliable. On the contrary, it demonstrates that the claimed instrument (for example a theory) is totally unreliable.

From this somebody might conclude that the reported 50% reproducibility is the best argument against the above mentioned excess heat. Such reasoning would be incorrect. When 50% of competent scientists see a disputed effect then that effect is likely to be real. I am thinking about a situation in which the number of attempts to confirm the discovery is large. In my opinion, arguments for or against cold fusion should not depend on the number of confirmations; they should be made on the basis of examinations of procedures leading to particular claims. Scientific experiments are not predictions; they are fact gathering attempts. On the other hand, claims should not be taken for granted unless the level of reproducibility, by competent researchers, is close to 100%.

2) Reproducibility is the most essential requirement in experimental science. Let me mention some questions linked with it. Some phenomena, for example, are very difficult to observe. The required instruments (satellites, accelerators, ultra-clean labs, etc.) are expensive and only a limited number investigations can be performed. How many confirmations are needed to accept a claim? That is one question; and here is another. Suppose that results coming from two teams of researchers differ by 30%. Does it mean that the claim made by one team is confirmed by another team? It depends on the nature of the claim. If the purpose of the experiment is to confirm the existence of a phenomenon, such as generation of excess heat, then the difference of 30%, in the amount of released energy, would not be significant. But a 30% discrepancy would be very significant if the purpose was to measure a physical quantity, such as length or current, very accurately.

3) Irreproducibility usually indicates that experimentalists are not aware that something is not the same when apparently identical experiments are conducted. In the case of cold fusion, according to many, the outcome depends on hard to control impurities and defects. This became apparent when electrolytic experiments with palladium cathodes were performed to confirm reality of excess heat. Electrodes supplied by one manufacturer consistently resulted in confirmations while electrodes supplied by another manufacturer consistently resulted in failures to confirm. Furthermore, excess heat was consistently observed with some batches of electrodes supplied by the same manufacture, and not with others. Hard to identify differences, perhaps at the very low level of contamination, are likely to be responsible for the absence of 100% reproducibility. Let me show how this was described by E. Storms. In the 2001 paper, downloadable from the library at <http://www.lenr-canr.org>, and entitled "Cold Fusion: Objective Evaluation," Storms wrote:

"Presence of reproducible patterns within the data sets are as important as achieving reproducibility of the phenomenon its self. Such patterns are based on AE [anomalous energy] being produced only under certain unique conditions by all studies. ..... The work at SRI, lead by Dr. McKubre, studied the phenomena, first with $6M provided by EPRI (Electric Power Research Institute). After this program was terminated, work was continued by IMRA (Japan) at nearly the same level. A very small effort is now being funded by the US government. Over the course of this work, several designs of flow-type calorimeters were used that share the following characteristics:

A. The cells are sealed and contain a recombiner. As a result, no gas leaves the cell. Therefore, uncertainty in the amount of recombination is not an issue. Successful action by the recombiner is monitored using different methods including change in gas pressure.

B. The cells contain a heater, which maintains a constant inner temperature. Power to this heater can be adjusted to compensate for any change in temperature caused by electrolysis or by anomalous processes. This heater is also used to determine whether the power measurement, based on the flow rate and temperature change of a cooling fluid, is accurate. Sensitivity better than ±0.01 W (±0.1%) is claimed.

C. The electrolytic cell, its surrounding heater, and the cooling-fluid channels are all contained within a silvered, evacuated Dewar in order to isolate them from the environment.

D. The whole assembly is immersed in a fluid bath, which maintains a constant environment of 30±0.003°C. This bath is also the source of cooling fluid. Consequently, most studies are done at a temperature above 30°C.

E. A constant flow pump is used to circulate cooling fluid. Flow rate is checked periodically by weighing the fluid passing through the calorimeter. Better than 98% of power produced within the cell is captured in this fluid.

F. All aspects of the measurement are under computer control, which provides continuous monitoring, and redundant RTD sensors are used for temperature measurement.

G. The deuterium content of the palladium cathode is determined by measuring its change in resistance.

Nineteen samples of palladium were found to make AP with consistent results. One consistent behavior is shown in Figure 1 as the relationship between AP and average composition of the cathode. Figure 2 shows another pattern as the effect of applied current on AP. These two behaviors are found to be produced by all samples of palladium used in this work and by all samples reported in the literature when the necessary measurements were made. Variations in reported values are easily explained by the different shapes and sizes of the cathodes used, and by the amount of active material present on their surfaces. In addition, the following behaviors are also seen by everyone who has made suitable measurements.

A. The average D/Pd ratio must exceed a critical value. This value differs somewhat between studies because only the

average composition can be determined and the value depends on the method used and the shape of the cathode. Typically, the value lies between D/Pd=0.85 and 0.90. Infrequently, compositions above this range are found to be dead for unknown reasons.

B. The current must be maintained for a critical time. This time is variable and presumably depends on how rapidly the surface can acquire the active structure. The time is zero for thin layers of Pd while it can be as long as months for bulk palladium. Failure to wait the necessary time is one reason some people have not seen the effect.

C. The current density must be above a critical value. Applied current determines the surface composition, hence the nature of the active structure. A value above 150 mA/cm 2is usually found for bulk palladium. No critical value appears to be necessary for thin layers of palladium.

D. Inert palladium can sometimes be activated by addition of certain impurities to the electrolyte. These impurities are found to help the surface achieve a higher deuterium content.

E. The effect occurs in only a small fraction of samples, but more often in certain batches than in other ones. In fact, all physical properties of palladium are found to be batch specific, making this metal highly variable in its general behavior, even in conventional applications.

These patterns of behavior add evidence that the observations are a real behavior of nature and not caused by error."

4) My accpted Letter to the Editorere of Physics Today (to appear in the September 2004 issue ?) ends in the following way. "".....I also agree with chemist Allen Bard that being able to reproduce experimental results is not good enough; it is only a preliminary step. But wasn't poor reproducibility the central point of criticism when cold fusion was first investigated 15 years ago? **In my opinion, experimental claims should not be disqualified solely on reproducibility; validation should depend on credentials of researchers and, above all, on methodologies they used in particular experiments.**"

164) A case of mutual deception?

Ludwik Kowalski (7/28/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

This morning I received an interesting private message from Teacher XX. It was probably prompted by voices reported in unit #161. But that unit is already too long. Furthermore, I think that this reflection deserves a separate unit. Is it possible that the disbelieve about cold fusion is nothing else but a self-fulfilling prophesy? Is it possible that those who believe in cold fusion are also victims of mutual deception?

Cold fusion and closed-loop self-fulfilling prophecies.

Teacher XX

Is the widespread disbelief in the reality of "Cold Fusion" based upon solid reasoning? Or could it be akin to a self-fulfilling prophecy or an "emergent phenomenon," as when each member of an animal herd rushes forward only because immediate neighbors in the herd are rushing forward? I imagine this conversation to take place between a research scientist and a journal editor:

Sci: Why is Cold Fusion (CF) an illegitimate topic?

Ed: Because there are no reports of CF observations by competent researchers.

Sci: Why are there no reports?

Ed: Because scientists don't submit them to journals.

Sci: On the contrary, I'm a scientist who does submit these to journals, which suggests that the dearth of reports is actually caused by rejections rather than lack of submissions. Why does *your* journal reject them?

Ed: Because everybody knows that CF is not real.

Sci: Why does everybody "know" this?

Ed: Because if CF was real, it would appear in many journals.

Sci: Why is CF not in one specific journal?

Ed: It's because CF is not already in many other journals, and that many journal editors couldn't possibly be wrong.

Sci: But why do the OTHER editors reject CF papers?

Ed: Well, the other journals must have a good reason, and I just follow the consensus expert opinion, and I assume that other editors have sharp minds, and this large group of experts couldn't be wrong about an important topic.

Sci: But what if all editors think exactly as you do: journal A rejects papers because they see no papers in journal B, and journal B rejects papers because they see no papers in journal A? Yet neither editor takes any CF paper seriously enough to sit down and read them with an open mind?

Ed: Well, that doesn't matter. We all know that CF is an illegitimate topic.

(go back to the top and continue.)

The above is obviously aberrant reasoning, where a population of minds can amplify the status of an initially-random opinion. The weak opinion
becomes strong because each member of the group puts great stock in the number of other members having the same opinion, so that a slight majority becomes an overwhelming majority, yet no new information justifies such certainty.

Another example is from 1905, when the Wright Brothers' claims were being ridiculed. This was back when they demonstrated their airplane repeatedly in public for more than a year. Why were there no news articles about the successful flying machine? Scientific American explained its refusal to verify the Wright's claims:

"If such sensational and tremendously important experiments are being conducted in a not very remote part of the country, on a subject in which almost everybody feels the most profound interest, is it possible to believe that the enterprising American reporter, who, it is well known, comes down the chimney when the door is locked in his face -- even if he has to scale a fifteen-storey skyscraper to do so -- would not have ascertained all about them and published them broadcast long ago?"

In other words, "we won't send a reporter, on the grounds that other magazines haven't send a reporter." Each editor also makes the unspoken assumption that those other editors must have a good reason. But what if all editors reason in the same manner? It's a self-fulfilling prophecy. That's what actually happened to the Wrights. The Wright brothers finally broke the jam by traveling to Europe where the closed-loop disbelief-reasoning had not yet emerged in the community. They demonstrated their airplane in Paris. News reporters DIDN'T refuse to attend, and the Wrights became famous overnight... this after more than a year of public demos in the USA at which no invited reporters or government observers ever showed up.

Another example involves "Ball Lightning." Today BL is increasingly considered to be a real phenomenon. But until the last two decades, the major portion of the scientific community was certain that BL was really just some misperceived retinal afterimages, if not hallucinations reported by crazies. On

what grounds did the community base its certainty?

Among other things, we reasoned that if Ball Lightning was real, then quite a few scientists would report seeing it, yet the reports came almost exclusively from the untrained public. The reason for this was not what you might expect. One investigator later questioned the staff of the Empire State lightning research project (which had set up automatic cameras to photograph the many strikes on the Empire State Building in NYC.) He discovered that a large proportion of the research crew had personally witnessed Ball Lightning. Why did they not report this? Because each was afraid of being labeled as a "lightning-ball quack!" It was a self-fulfilling prophecy: scientists were afraid to report a real but "illegitimate" event, and the event became labeled as "illegitimate" mostly on the grounds that, if it was real, scientists would already be reporting the event. The switch flipped, certainty arose, but it arose because of a runaway feedback loop.

The problem caused by community-wide closed-loop reasoning is also mentioned below in regards to the "illegitimate" status of research into hypnotism:

The Research Game (See item no. 2 about new fields of science)
<http://amasci.com/freenrg/rules.html>

The late Dr. Thomas Gold describes the problem of the unwarranted "sharpening" of community opinion. Certain researchers are trimmed out during each round of competition for funding; rejected on the grounds that they are "outliers." This trimming-of-outliers happens repeatedly until a consensus opinion rules the research community:

165) Names and definitions

Ludwik Kowalski (7/31/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

In the introduction to his 2001 paper, already mentioned in unit #163, Edmund Storms commented on the name cold fusion. He wrote: "This process was first named 'Cold Fusion' by Steven Jones - an especially poor description." The alternative descriptions: LENR (low energy nuclear reactions) and CANR (chemical assisted nuclear reactions), are subsequently introduced as a replacement. To this one may a recently introduced name CMNP (condensed matter nuclear phenomena). I tried using other names but decided to return to the old name, cold fusion. Most people at once know what i am referring to, especially when the adjective "nuclear" is added.

In meeting Storms last year I noticed that he was not using the LENR and CANR; he used the term cold fusion, like everybody else at the conference. But is this name really a poor description? When I visited Steven Jones last January I asked him if that name is appropriate. He thinks it is, at least for emission of neutrons and charged particles, described by him at 10th International Cold Fusion Conference (see my unit #113). I tend to agree with Steven; the name cold fusion is likely to be appropriate for rare events he is observing but is a poor generic name for the entire field. Yet, it is commonly used as a generic name.

I think that Fleischmann and Pons had no experimental basis for saying, in 1989, that excess heat they measured had nuclear origin. In that context I would agree that the name was "an especially poor description." It generated a lot of unnecessary confusion and hostility. Today, however, the term cold fusion seems to an appropriate description of the process in which excess heat is generated. I am saying this because generation of heat has been shown to by production of ^{4}He at the rate of one atom per 24 Mev of excess heat. The issue of name should not be confused with the issue of definition. Any descriptive name can be introduced to describe a new phenomenon, preferably not a name already used to describe something else. But the definition of the meaning behind the name is much less arbitrary. Some definitions, as described in unit #136, are more appropriate than others.

P.S.
According to "Word iQ" online encyclopedia, "the term **cold fusion** was coined by Dr. Paul Palmer of Brigham Young University in 1986 in an investigation of 'geo-fusion', or the possible existence of fusion in a planetary core. It was brought into popular consciousness by the controversy surrounding the Fleischmann-Pons experiment in March of 1989." Details about prehistory of cold fusion are described by Steven Jones in unit #131. In reading that description one finds another old name, worth mentioning. It is "piezonuclear fusion." This 1988 term refers to fusion in planetary cores, or, more generally, under extremely high pressures. By the way, is it reasonable to suspect that such fusion takes place in the sun,

somewhere between its nuclear core and its surface? I am thinking about a gradual transition from hot fusion (in the core) to much less hot fusion near the surface.

166) Eugenr Mallove was a scientific reporter, not a research scientist.

Ludwik Kowalski (8/5/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

I would like to comment on a paper by Eugene Mallove, late editor of Infinite Energy magazine, and author of the 1991 book “Fire from Ice.” The paper, available at:

<http://www.infinite-energy.com/resources/iccf10.html>

was presented at the 10th International Cold Fusion Conference in August 2003:
His presentation was very different from papers offered by research scientists. Eugene, whose tragic death was a great shock to many of us, was a journalist, with scientific background, and an enthusiastic supporter of others’ unconventional ideas . As far as I know Eugene was not involved in laboratory research. His last paper summarized three such ideas: “cold fusion”, “hydrinos” and “vacuum energy.” Each of them is identified as an “emerging energy technology.”

At the conference, I told Eugene that it was not reasonable to say that something was an emerging technology when scientific principles on which it was based were in conflict with existing scientific knowledge, and when experimental data were not yet 100% reproducible. His review was very interesting but its impact was not as strong as it would have been if the author were a professional physicist or chemist. After reading the paper I decided to ignore “hydrinos” and “vacuum energy” because I was not at all convinced that “cold fusion,” in which I am interested, has anything to do with these topics. Some comments on hydrinos can be found in units # 57 and 89 while comments on vacuum energy can be found in unit # 162. Cold fusion is already sufficiently controversial; mixing it with other controversial topics makes it much less credible.

I do not mean to say that Eugene's paper is not worth reading. On the contrary, it is an excellent example of creative writing. Let me quote the abstract and the beginning of the first section. I suggest that names found in the abstract should be used as keywords in additional Internet explorations. Keep in mind that LENR stands for “Low Energy Nuclear Reactions,” a new name for cold fusion.

LENR and "Cold Fusion" Excess Heat:
Their Relation to Other Anomalous Microphysical Energy Experiments and Emerging New Energy Technologies

(Eugene F. Mallove, Sc.D.)

Abstract
During the past 15 years, indisputable experimental evidence has built up for substantial excess heat (far beyond ordinary chemical energy) and low-energy nuclear reaction phenomena in specialized heavy hydrogen and ordinary hydrogen-containing systems. [1] The primary theorists in the field that is properly designated Cold Fusion/LENR have

generally assumed that the excess heat phenomena is commensurate with nuclear ash (such as helium), whether already identified or presumed to be present but not yet found. That was an excellent initial hypothesis. However, the commensurate nuclear ash hypothesis has not been proved, and appears to be approximately correct in only a few experiments. During this same period, compelling evidence -- although not as *broadly* verified as data from cold fusion/LENR -- has also emerged for other microphysical sources of energy that were previously unexpected by accepted physics. The exemplar of this has been the "hydrino" physics work of Dr. Randell Mills and his colleagues at BlackLight Power Corporation, which was a radical outgrowth from the cold fusion field that emerged publicly in May 1991.[2] Even more far-reaching is the work in vacuum energy extraction pioneered by Dr. Paulo and Alexandra Correa, which first became public in 1996.[3] This vacuum energy experimentation began in the early 1980s and has been reduced to prototype technological devices, such as the patented PAGD TM (pulsed abnormal glow discharge) electric power generator, as well as many published experiments that can be performed in table-top fashion to verify the Correa "Aetherometry" (*non-luminiferous* or *non-electromagnetic* aether measurement science).[4] In an era when mainstream science and its media is all agog about "dark matter" and "dark energy" composing the vast bulk of the universe, there is a great need to reconcile, if possible, the significant bodies of evidence from these three major experimental and theoretical streams: cold fusion/LENR, hydrino physics, and Aetherometry. The aim of the present paper is to compare the substantial features of each field of investigation and to suggest how to move forward for the benefit of all with openness and a minimum of preconceptions.

Introduction

On the surface, all seems calm -- at least to the so-called Scientific Establishment, in other words the mainstream scientific media. The latter includes *prominently Science, Nature, Physical Review, Scientific American, American Scientist, The New York Times* "Science Times," and a host of other publications, which alternately ignore, mock, or misrepresent those scientific findings hard-won in laboratory experiments, such as are represented in the better papers that are presented at Cold Fusion/LENR conferences such as ICCF10. And, the major peer-reviewed publications in this Establishment do not accept papers on low-energy nuclear reactions and "cold fusion" phenomena -- these are not even given entrance (since the 1989-90 period) into the vaunted peer review process. This fact is neither admitted publicly by the obstructing publications, nor noted by the community of science journalists, who should be among the first to investigate and expose this blatantly anti-scientific publication practice.

To the Scientific Establishment all is calm because there are no phenomena from table-top experiments that are allowed to challenge the basic foundational physics paradigms, which have been laid down to become what can only be described as a church-like "holy writ." It is almost as though we are back in 1894 when the sentiment expressed in the above quote of Albert Michelson prevailed -- all is well with Physical Science and "further advances are to be sought chiefly in the rigorous application of these principles to all the phenomena which come under our notice." That is essentially the dogma of mainstream physics circa 2003. Moreover, most scientists in the cold fusion/LENR field, whose experimental work is rejected by the mainstream, do not wish to challenge the foundations of physics either; they believe that cold fusion/LENR does not challenge those foundations at all and that their observations can be or will be explained by prevailing quantum mechanics and relativity theory.

The last sentence above is an excellent description of what makes Eugene's paper drastically different from papers presented by research scientists studying cold fusion. Those scientists try to understand strange experimental results in terms of accepted theories; Eugene, on the other hand, urges them not to be bound by the existing paradigm. Such advice does not seem to be reasonable when experimental results, obtained by highly trained scientists, are still not yet 100% reproducible. And something much better than 100% reproducibility is needed to challenge the legitimacy of

“quantum mechanics and relativity theory.” It will be up to theoretical physicists to decide whether or not accepted theories conflict with 100% reproducible experimental data.

Eugene was certainly aware that scientists and humanists belong to two different camps, with regard to methods of validation of various claims. His writing about science, in my opinion, is excellent because it appeals to both non-scientists and scientists. I like it because it focuses on social and philosophical aspects of cold fusion; it promotes communication between two cultures--scientists and people in other areas of intellectual activity. This paper, however, made me aware that some of his formulations, intended to promote “our cause” might actually hurt it. The demarcation line, defined in the last sentence of the above quote, should help us to see Mallove’s activities in proper perspective. I bow my head to the enthusiastic defender of cold fusion. The criminal hands that killed him ended a slowly developing line of new friendship. It is so unfortunate that his own reply to this item will never be seen. Let me end these comments with another qoute from Eugene’s introduction. A section describing our existing paradigms ends in the following poetic way:

Paradigm 7: The Second Law of Thermodynamics can never be violated in macroscopic systems. One cannot make a “Perpetual Motion Machine of the Second Kind” that would convert ambient thermal energy to useful work, with no heat rejection into a lower-temperature reservoir.

The foregoing is a highly restrictive set of dogmas within which scientists are expected to conduct their work. There can be no doubt that these are the intellectual walls that the Scientific Establishment has erected. True enough, a huge amount has been learned about Nature within the confines of these paradigm restrictions, and much technological progress has occurred too -- but there is so, so much more to the universe and to what human beings surely will be able to do and become if they could be liberated from those restrictions! . . . I respectfully disagree with [this] conference chairman Professor Hagelstein that *all* heat engines will be forevermore fundamentally Carnot-limited.

Once again Eugene draws a clear line between himself and an active cold fusion scientist from MIT. Eugene does not claim to be a researcher, he sees himself as advisor and philosopher. Perhaps somebody who knew him better will elaborate on my quick observations. I would be happy to append additional comments about “two cultures,” in cold fusion. (The “Two cultures,” by the way, was the title of a book by C.P. Snow.; the book was published long before the cold fusion controversy.)

167) A lot of noise about a speculation

Ludwik Kowalski (8/6/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

In browsing the Internet I found this document:

http://www.aetherometry.com/wilson_response.html

It is "An Open Letter to Mr. J. Wilson of Popular Mechanics" from Dr. Paulo Correa. Mr J. Wilson is a senior editor of Popular Mechanics, a journal in which a very short article on cold fusion was published recently (August 2004). Correa, accuses Wilson of turning a legitimate topic of general interest into a science fiction story about homemade hydrogen bombs.

Correa writes: ". . . What you have produced is pure sensationalistic hype - worthy of a second-rate rag. You mixed ill-digested facts with false allegations that you attributed to Dr. Mallove, in order to cook the eye-catching stew of mass-hysteria and paranoia that the cover so successfully conveys. You saw fit, in this age of rampant terrorism, to tell to your readers a scary bed-side tale - instead of doing your homework as a Science Editor. You preferred to concoct a science-fiction story of an imaginary horror, rather than educate your readers about the physics and potentialities of LENR. You knew it would sell like hot cakes, and so, overnight, 'cold fusion', which only yesterday was an affair of crackpots and was being suppressed for a falsely attributed 'lack of merit', became so meritorious and so dangerous as to deserve to become an affair of State, Army and Intelligence. ....."

Who is Dr. Correa? His name appears in Mallowe's abstract (see unit #166 at my website). Here is how his work is described by Jeanne Manning in:

http://www.earthpulse.com/science/zeropoint.html

"A Canadian couple also say they have made a breakthrough in non-polluting power generation with an invention that delivers more power than it consumes by using pulsed cold plasmas. Dr. Paulo Correa and Alexandra Correa kept the process a secret until recently, when three US patents were issued." In the same piece Manning observes: "Free energy, electricity from space, zero-point energy from the quantum fluctuations of the vacuum of space... Whatever the name of the previously-unknown source of energy that is seemingly tapped by an emerging energy technology, the proof for its existence is multiplying exponentially." In another Internet reference Paulo Correa is described as "Partner and Director of Research at Labofex -- Experimental and Applied Plasma Physics of Concord, Ontario." He is said to be an inventor of a highly desirable process. "Unlike the cold fusion process, which claims to output low grade heat, the Correa technology directly generates electricity at power voltage levels, without any utilization of cold or thermonuclear fusion principles. Another important feature of the apparatus is that it employs no radioactive compounds and generates no nuclear radiation or radioisotopes. The energy system is entirely pollution-free, self-contained and composed of readily recyclable materials."

Intrigued by Correa's "Open letter", I went to the library and read the Popular Science article. It seems that Correa makes a lot of noise about nothing. The short article is a speculation that cold fusion can possibly be used to produce large amounts of tritium for hydrogen bombs. Correa dismisses this as a "scary bed-side tale." In my opinion that speculation is not less realistic that a speculation about economically significant energy from cold fusion, as envisioned

by Mallove. Most cold fusion researchers know that tritium is not the main byproduct of cold fusion. Sending a beam of deuterons (from an easy to construct electrostatic accelerator) into heavy water would probably generate much more tritium, in one or two days, than all cold fusion reactions so far.

But the fact that this radioactive isotope of hydrogen has been detected in many laboratories is significant; it indicates that a highly unusual nuclear process was occuring in some cells. This observation was made in the same year in which the discovery of cold fusion was announced. But it significance was often dismissed on the ground of possible contaminations. I hope that claims of generation of tritium and helium will be taken seriously by scientists appointed by DOE to reinvestigate cold fusion. Nobody knows what kind of practical applications, if any, will emerge after the reality of cold fusion is recognized.

168) An essay by Mark Hugo

Preface

Ludwik Kowalski (8/13/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

1) **In an e-mail message, received** three days ago, Mark Hugo wrote: “I've taken the liberty of attaching a 26 page pdf which details results from a lab in Kiev, Ukraine. Whether or not "Cold Fusion" is real, Dr. Adamenko, a long time stellar THEORIST was stimulated by the results of P&F and others to rethink his beliefs and theories on stellar action during the '90's. As a result of this rethinking, and because of some odd spark of genius, from 2000 onward, he has been experimenting with "coherent electron bunches" and their impact on "heavy elements". As you will see in reviewing the attached booklet.pdf (taken from www.proton21.com.ua) the result of these interactions is not only massive nuclear transmutations for energies under 10,000 eV per transmutation (miracle #1), but also the formation of easily measurable (by Mass Spec) amounts of Super Heavy Elements. (Shall we say miracle number 2.) All in all, there is a stunning amount of evidence here of phenomenon which needs careful attention to be paid to it.”

2) **In my reply, sent last night (8/12/04),** I wrote that, after reading Adamenko and Vysotskii paper, presented at the ICCF10, I do not think that the reported experiments belong to the area of cold fusion. A very short pulse of electrons, delivering 1 kJ of energy to a tiny spot (10 to 100 microns) on a target, might be responsible for a very high momentary temperature. Looks like a hot plasma setup to me. The experimental results are sensational but I am in no position to judge them. They performed 5000 experiments. That is very impressive. I also asked Mark if he could write a short summary of Adamenko’s work for a typical physics teacher, for example in a high school or college. I would be happy to post such paper on my web site.

3) **This morning Mark Hugo wrote:** “. . . Now one other thing, there is much MORE than 10^{18} atoms which receive the 1 KJoule of input energy. Probably more like 10^{21} atoms. Thus the actual energy input per atom in the target samples is closer to 10 eV. At this level we can definitely say we are in the "chemical energy" range. There are NO nuclear events which should be occurring, PERIOD. (But the experimental evidence is that they ARE occurring.) I'll take some time this weekend and give you a write up in a form that college level and high school level physics students can understand.

With 20 years of experience in nuclear power ... plus my current position as a ‘Materials Scientist’ for Hutchinson Technology, I AM in a position to judge the experimental work. Doing experimental work with materials is my "bread and butter". So I HAVE had experience with Xref, Auger, ESCA and Mass Spec many times over the last 20 years. WITH this experimental background I can say this: UNLESS ADEMENKO IS FRAUDULENTLY FABRICATING his experimental data, his data backs up all his claims. (I.e., nuclear transmutations at ‘cold’ conditions, and generation of super heavy nuclei ... using a method which bears NO relation to ‘high energy’ physics. That's where we need to start!”

4) I am still waiting for Mark’s essey (8/17/04). I strated looking for information about Adamenko over the Internet. His private Ukrainian lab (EDL, in Kiev), has a web page: <http://www.proton21.com.ua/index_en.html>; it is worth reading. It sais that the project is “based on an innovative and original conception on initiating extreme conditions for nucleosynthesis process ignition in a super-dense cold substance.” At the February 2004 workshop in Germany Adamenko said: “Briefly described is the author’s conception of shock coherent collective cascaded cumulative mechanism of particles acceleration through initiating the self-developing collapse of a converging solitary shell-wave of extreme density of energy and substance. Also provided is some part of experimental data obtained in course of

practical implementation of that concept. The paper is aimed at preliminary discussion of the composition and content of collected works describing the experimental and theoretical results obtained in the Electrodynamics Laboratory of Proton-21 company in Kiev, Ukraine. This work has been carried out within the commercial project called Luch, which is developed on our initiative and aims at the creation of new, efficient and environmentally safe nuclear technologies for neutralizing the radioactivity and synthesizing stable isotopes of chemical elements, including superheavy ones."

Luch, by the way, is a private research laboratory in Russia (near Moscow). Karabut, whose work was described in unit #13, works in that laboratory. Once again I am impressed by highly unusual isotopic ratios among the reaction products. Here is an illustration:

^{90}Zr --> 6% abundance in reaction products versus 51% in nature
^{92}Zr --> 31% abundance in reaction products versus 17% in nature
^{96}Zr --> 39% in reaction products versus 2% in nature

It appears that their compression process, which I do not understand, produces less proton-rich nuclides and less neutron-rich nuclides than found in nature. Will this experimental fact be confirmed by other qualified scientists? Showing that something highly unusual is taking place is always very important, even if the process cannot yet be comprehended. I am puzzled by the phrase "shock coherent collective cascaded cumulative mechanism of particles acceleration." I suppose that "coherent electrons" are electrons hitting the target at essentially the same time. What else can it mean in this context? The term "driver" probably refers to an electron accelerator with a photo-electric cathode. That cathode is bombarded by a pulsating laser beam. This produces bunches of electrons that are accelerated together. I happen to be know people working with such machines in the US.

What impressed me most was formation of transuranium elements. Contamination by impurities can not possibly be responsible for atomic nuclei characterized by atomic masses above 250. Such nuclei have never been found in our natural environment. At a recent workshop in Bonn (Germany, February, 2004) the authors reported the synthesis of nucei with atomic masses 253, 264, 278, 280, 294,395, 433 and 434. That is what Mark Hugo calls Miracle #2. I wander if Darmstadt heavy ions physicists were present at this workshop and how they reacted to the report. They, and scientists from Dubna (Russia), are experts in syntesizing superheavy nuclei. (These experts, by the way, use the term "cold fusion" to describe rare collisions of two atomic nuclei at sub-coulomb kinetic energies. The process in which superheavy nuclei are presumably synthesized by Adamenko et. al., seems to be very different.)

4) **P.S. (8/16/04)**
While waiting for Mark's essay I found something puzzling. By going to Ademenko's website, <http://www.proton21.com.ua/about.html> one can ask for the description of the laboratory in two languages: Russian or English. Reading it in Russian I see the phrase "perierozhdienije jadernovo veschestwa." This translates into "rebirth of nuclear matter." I think that the term "reorganization of nuclear matter" would be more appropriate, unless "zero point energy" is involved. Do they think that nuclear matter disappears for a moment and then reappears in new form? To see how the "perierozdhienije" was translated I clicked on the "English" button. But the English text is not the same as the Russian text. Why is it so? (In reading their ICCF10 report again I saw that "perierozhdienije jadernovo veschestwa" was translated as "nuclear regeneration." I was not familiar with this term.)

Here is my translation of the above Russian document.
"The laboratort of electrodynamic studies (EDL) was created in 1999, to implement new and save technology of processing radioactive waste. The method is based on the author's hypothesis concerning a possibilty of simulating a previously unknown natural process. That self-organizing process, the avalanche-like collapsing (concenteation of energy) in condense matter, can possibly result in complete rebirth of nuclear matter. First experimental confirmation of that idea, by using a specially constructed setup, occurred on Ferbruary 24, 2000. It was a demonstration of the electro-nuclear collapsing to extreme (microscopic and quasi-point-like) densities.

Several thousand successfull experiments were conducted between 1999 and 2003. Acting on soid state targets, we observed their specifically explosive destruction accompanied by emission of transformed (artificially synthesized) matter. Artificial generation of matter, generated in explosive destruction of targets, was confirmed through more than

15,000 analytical experiments, using the most modern equipment, conducted in other laboratories, not only in Ukraine, but also in Russia and USA. We can definitely conclude that:

1) Experimentally effective technology was created and confirmed. It provides conditions under which new kind of nuclear reactions (collective multi-particle processes in condensed matter) become possible for the first time in world's history.

2) An experimental setup was created to initiate energy-efficient and highly productive process of artificial synthesis of nuclear matter.

3) Products of artificial synthesis contain no radioactive isotopes.

4) In working with radioactive targets we definitively observed the decrease of radioactivity resulting from the complete nuclear rebirth in the parts of material after highly-energetic processing.

5) Products of artificial synthesis contain long-lived superheavy atoms of unknown chemical elements (at the border and outside the border of the periodic chart). The products are synthesized at rates which are many order of magnitude higher than in classical, less energy-effective methods."

Here is the text displayed after the "English" button is preassed on that page:
"Advancements over the span of the last fifty years in many fields of scientific and technological research such as Genetics, Physics, Telecommunications and other fields has outperformed progress in the field of Power Generation and Decontamination of Radioactive wastes. Progress in the fields of controlled thermonuclear synthesis and radioactive wastes decontamination technology also lag in comparison despite investments in research by the developed nations exceeding USD 100 billion. One key issue that remains unresolved to this date in this particular field of research is the development of processes and technology for controlled ignition of self-sustaining nuclear reactions. For this, an adequate "initiator" of such controlled nuclear transformations is required; one which will result in a sustainable and controlled energy output and the transmutation of radioactive atoms into stable ones.

ElectroDynamics Lab (EDL) was founded in Kiev, Ukraine in 1999 by a group of Ukrainian engineers and scientists to address the specific problem of the adequate initiator. EDL's primary mission statement was to develop a novel, safe and effective technology for radioactive wastes decontamination. Today, privately funded EDL has evolved into a leading edge Research and Development center employing in excess of 120 researchers and scientists. The proven results of its research and its proprietary process, currently being patented, are able today to address the unresolved issue of nuclear wastes transformation. EDL's results are revolutionary in their nature and are leading to important commercial and industrial breakthrough applications."

I will assume that the Russian version is more recent because it gives more details. On the other hand, it may be the other way around; perhaps they no longer believe in the rebirth theory. This does not make any difference to me; at present I am interested in strange experimental results, not in theories.

4) **P.S. (8/22/04)**
Still waiting, I went back to <http://www.proton21.com.ua/index_en.html> and clicked on the "our news" button. In the window that opened I noticed some new pdf files. The first that I downloaded was Decay_IMS3f_en.pdf. It shows that alpha particles of up to 430 MeV were observed (November 23, 2003) with a Si detector from a foil that was bombarded with 12.5 keV oxigen ions. This experimental results is not less shocking than their observation of stable transuranium nuclides.

The second downloaded file, Decay_LMS_en.pdf, shows that alpha particles were onserved with CR-39 when the foil was bombarded by red light from a laser (delivering 50 mJ/14 ns pulses to spots of target areas whose diameters were ~0.5 mm). This translates into about 3 million watts. As I said before, this is not a typical cold fusion wattage. But results are impressive. On the exposed CR-39 surface they found 149 alpha tracks (versus only 18 tracks on the other surface.

I also downloaded files containing two reports (dated April27, 2004) on methdology and results from recent experiments. I will read these papers later.

5) **Mark's essey was received** this morning (8/23/04). He wrote explained the delay and added an observation. "There is one little ray of hope for Dr. Adamenko's work. Since he started in the '80's and '90's as a 'Stellar Theorist', and was widely published and acknowledged, he has an 'in' with that 'community'. As such, he has been quietly, but deliberately showing up at a variety of 'Astro Physics' and Stellar Physics conferences and presenting his results. To date (August, 2004) however, interestingly THERE IS NO DISCUSSION OF HIS RESULTS available ANYWHERE PUBLICALLY. Only his OWN publications. [Another example of] the "benign neglect?" WHY there is no discussion?"

I do not know how to answer this question. To promote discussion I would select one easily reproducible experiment and would focus on it in all publications and talks. It is not easy to think critically about results of 5,000 experiments. And I would publish a complete description of the so-called "coherent driver" of electrons used to generate nuclear transmutations. A discussion would occur spontaneousely if essential instruments were available to perform experiments in other places.

Simulating nucleosynthesis on earth?

Mark Hugo, August 23, 2004
Argon Engine, Excelsior, MN , USA
THREESPOT@aol.com

Since 1999 experiments have been performed at the "Electrodynamics" lab outside of Kiev, Ukraine using "coherent electron bunches" to stimulate nuclear transformations in "heavy elements". To understand the significance of these results a brief review of some basic nuclear physics is in order. According to a reference on nuclear technology: "In 1932 Cockcroft and Walton produced the first nuclear reaction using artificially accelerated particles, bombarding and disintegrating lithium nuclei with protons accelerated to several hundred keV. By opening and closing switches in proper sequence they could build up a potential of 800 kilovolts. (Thus an 800,000 eV particle). This gave the potential to accelerate protons down an evacuated tube eight feet long. They then put a lithium target at the end of the tube and found that protons disintegrated a lithium nucleus into two alpha particles. "

Actually this is not quite correct, as the first "nuclear reaction" observed was found in 1919 by Ernst Rutherford, using collisions with naturally occurring alpha emitters. (4,000,000 eV). Nevertheless this gives us some insight into the energy levels involved in nuclear science. Starting with the Cockroft and Walton work (at 800,000 eV and moving upward) fundamentally all reactions involving re-arranging the nucleus fall into the realm of 1 million electron volts and above. This has to do with the fact that the "binding energy" between a proton and a neutron in a nucleus is on the order of 1 to 2 million eV, and has to be overcome to re-arrange a nucleus.

There are two "exceptions" to this rule, however. One is the "nuclear reactions" which a produced by adding a neutron to a heavy nucleus (200 plus atomic mass units.) This sort of reaction can involve very LOW particle energy, but demands a source of NEUTRONS to allow it to happen. Also, all known neutron stimulated nuclear reactions (referred to as "fissions") result in highly "energized" end products, which are colloquially referred to as "nuclear waste". (I.e., they are in an unstable nuclear state and continue emitting gamma, beta radiation and alpha particles after they are formed.)

The other "exception" is the nuclear reaction of "fusing" two light nuclei (<12 AMU) together. Technically this can happen with energies of just above 10,000 eV. However the "target cross section" of these reactions is so small as to make their probability very low for happening in conventional particle beam devices at energies that low. Now we come

to the work by Adamenko. Here is an example of a "heavy element" sample from Adamenko's work before it is exposed to a bunch of electrons delivering 1 Kilo-joule of energy.

Note that this is a 99.99 % pure ball of copper. After a 1 kilo-joule coherent electron blast the following is obtained:

You will notice more than a dozen elements in this analysis. This sample is on the original Cu "plate" that the original Cu "ball" was on. Careful analysis (using standard methods, EDAX, XPS, combined with Mass Spec work) by Dr. Adamenko has indicated that 10^{18} atoms have undergone "nuclear transmutations" in these samples. The highly unusual nature of these transformations becomes clear when the amount of energy per reaction is calculated. One kJ translates into 6.2 X 10^{21} eV. Therefore, only $6.2*10^{21}/10^{18}$ = 6,200 eV of energy is used, on the average, per per nuclear event. This is about 1600 times less than a typical binding energy of 10 MeV. of Dr. Adamenko. But this is not the only "anomalous" result reported by Ukrainian scientists. Another highly unusual result is detection of transuranium elements. Transuranium elements discovered by Dr. Adamenko appeared in large quantities (sufficiently large to be observed with a mass spectrometer). Furthermore, they did not decay rapidly. This can be contrasted with what is known about transuranium elements synthesized in nuclear reactions induced by heavy ions. In these reactions the amount of energy per event is higher than 100, 000, 000 eV per event.

The mass spectrometer output below has a peak due to the element whose atomic number is 115. It was produced when copper was bombarded by electrons.

The peak in the 328 to 330 mass would be the "Element 115" trace. The 338 to 433 peaks are due to elements with even higher atomic numbers. The Cs_3C_2 and Pb_2O shown on the second mass spec are there for reference. They are the only known compounds that would fit in the realms shown. The nature of the "mass spec" work is that it would tend to break the chemical bonds of the Cs/C or Pb/O combinations and resolve only the Cs, C, Pb or O individually, so it is UNLIKELY that even if the compounds existed they would show up in the mass spec results as combined.

Now without belaboring detail, the only way that mass spec signals in these realms could be detected would be with numbers such as 10^{13} or 10^{14} atoms or above in "real" terms. Thus not only is the energy levels which Dr. Adamenko making "Super Heavy Elements" divergent from the "High Energy Physics" community by a factor of 30,000 but also the "end production result" is off from the H.E.P. groups by 10^{12}. This means, of course, that there is an insanely huge gulf (right now) between the standard "high energy physics" community and the work being done by Dr. Adamenko. How do other scientists deal with this difficulty?

There are usually two approaches I have seen to this sort of situation. Number one, is …as in Pons and Fleischmann's work, to be tremendously demanding and take advantage of "perceived weakness" in the experimental work, and to pick it apart. There is one other method of response to such "revolutions" I have also found. That is what is called "benign neglect". (Or the , "ignore it and it will go away" or the "PAY NO ATTENTION THE MAN BEHIND THE CURTAIN" response.) A good example of the latter is the response that Dr. George Miley of the U. of IL has gotten to his I.E.C. fusion results. (Inertial Electrostatic Confinement Device). Miley's IEC devices are WILDLY more successful (although they cannot generate NET energy output, not yet..) than the 500,000,000 Dollar Princeton Tokomak (R.I.P.) or the equally expensive Lawrence Livermore "Shriva" laser pellet fusion device(s).

Miley spent $20,000 and 3 graduate student's time (for a year) building his I.E.C. device. But does one find the "Fusion research community" beating a path to Dr. Miley's door? NO! In point of fact, because Dr. Miley was worked on "Cold Fusion" devices, he has been pilloried as a "quaint crank", who is getting "funny" as he ages. Fortunately, George is the type of personality that doesn't bow to "external" pressure, and he continues on with his interesting and progressive work. (Although with only a FRACTION of the funding the "give us another BILLION, and in 10 years nuclear Fusion will only be 10 years away" crowd.)

Getting back to Dr. Adamenko, there is one little ray of hope for his work. Since Dr. Adamenko started in the ‘80’s and ‘90’s as a “Stellar Theorist”, and was widely published and acknowledged, he has an “in” with that “community”. As such, he has been quietly, but deliberately showing up at a variety of “Astrophysics” and Stellar Physics conferences and presenting his results. To date (August, 2004) however, interestingly THERE IS NO DISCUSSION OF HIS RESULTS available ANYWHERE PUBLICALLY. Only his OWN publications.

169) Laser-activated excess power

Ludwik Kowalski (8/28/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Looking for news about cold fusion (with Google) I found “The New Light on LENR” by Jones Beene: It can be seen at:

http://www.zpenergy.com/modules.php?name=News&file=article&sid=887

This recent piece(8/17/04) is essentially a reflection on the paper of Letts and Cravens: "Laser Stimulation Of Deuterated Palladium: Past And Present." That paper was presented at the Tenth International Conference on Cold Fusion last year. It can be downloaded over the Internet as:

http://www.lenr-canr.org/acrobat/LettsDlaserstimu.pdf

Beeme thinks that it is “the most important paper in LENR in 15 years.” This strong endorsment forced me read the paper again. I agree that the results are interesting but I see no evidence that they have anything to do with LENR (Low Energy Nuclear Reactions). I have no idea what is responsible for generation of excess heat; why should I assume that it is due to nuclear reactions described by Beene? In trying to answer this question I found an interesting “appeal to researchers” posted by D. Cravens and D. Letts today <http://www.cerg.org/research/publications>

The author of that document states that “demonstrable transmutations in suitably prepared metals have been reported recently under ‘low energy’ laser stimulation.” That is a different story; the term transmutations is commonly used as a reference to nuclear reactions. I agree with the author that a 30 mW laser beam, uniformly distributed over the area whose diameter is 2 mm, can not possibly generate stellar temperatures. But I would like to know more about the recent “demonstrable transmutations.” In their appeal Dennis Letts (from Texas) and Dennis Cravens (from New Mexico) offer other scientists a possibility to study their samples. Will presence of products of nuclear reactions be confirmed? I responded to the appeal offering an investigation with CR-39 detectors. This was a week ago. The reply came last night; I will have a chance to examine their cathode #163. Waiting for that cathode I will now start summarizing findings the Letts and Cravens.

The “appeal to researchers,” at the above URL, contains links to several pdf files with “related publications.” I downloaded the first of them: “Practical Techniques in CF Research – Triggering Methods.” This paper was presented by Cravens and Letts at the last International Conference on Cold Fusion (ICCF10). It can be downloaded from <www.lenr-canr.com> . the document shows that the authors have been working of the subject for 14 years and performed “thousands of experiments.” Referring to the irreproducibility they wrote: “Electrolytic cells using bulk palladium often require loading times of 10 to 20 times longer than would be expected by diffusion times of deuterium within the metal before they be expected to produce excess heat (1). This was likely the cause of failure of early researchers who rushed to replicate Fleischmann’s and Pons’ early work (2). In the first few years after the announcement, it was easier for a researcher to rush to print and claim negative results than to patiently wait until the system was fully loaded and driven into internal transitions that drive the reactions. As a result, early work more often than not failed to see excess heat.”

The introduction contains another interesting observation. Referring to Schwinger, and to more recent theoreticians, the authors wrote: “Most simple theoretical models fail to predict that nuclear reactions within a deuterated metal lattice can

take place at significant rates. Such models rely on reaction rates that are based on equilibrium placement of deuterium within a metal lattice or on wave functions based on such placements. In particle models, the global average of the deuterium density within the metal is on the order of an Angstrom or more even for extreme loading ratios of D/Pd. It is clear that deuterium at such remote nuclear separations would not be expected to lead to nuclear events.

The imposition of dynamic conditions can cause the local separations of deuterium to be significantly different from the value predicted by the global density alone. It also seems that dynamic conditions provid[ing] ways for coupling of energy to drive the reactions and impurities within the lattice can allow for spin exchanges required for spin selection rules. It is a surety that the energy required to drive any nuclear events and energy released from such events are much larger than any external energy available to the deuterium based on a per atom division of energy (3). This means that any external energy driving the possible nuclear events must act in a coherent way to channel energy from a large region of many atoms to the active sites (4,5,6).

This coherent channeling must involve over 10^8 atoms and likely many more. The experimental conditions then must make use of non-equilibrium events acting on a system that has some group coherent nature. The methods described here are simple and practical methods that can be used to produce such dynamic conditions, which may lead to the desired nuclear events. The assumption here is that the reactive nuclear species must be driven to a dynamic active state before the desire events can produce excess energy within the system."

This would be a good reply to those who formed their opinion about cold fusion in 1989 and 1990. But general observations of that kind do not substitute for identifying conditions under which unexpected nuclear reactions are reproducible. I have no doubt that quantitative theoretical models will be found, sooner or later, after cold fusion phenomena become 100% reproducible. Why should situations in cold fusion be different from situations in other areas of science? Let me now focus on another paper that Letts and Cravens presented at the same conference. That paper, entitled "Laser Stimulation Of Deuterated Palladium: Past And Present," can be also be downloaded from< www.lent-canr.org> . The authors discovered that laser light can trigger generation of excess power in suitably prepared materials. Here is the abstract of their paper:

"A method is disclosed to fabricate a Palladium cathode that can be electrolyzed in heavy water and stimulated with a laser at a predetermined wavelength to produce apparent excess power; the fabrication method involves cold working, polishing, etching and annealing the Palladium prior to electrolytic loading with Deuterium. Loading is accomplished with the cathode sitting in a magnetic field of 350 Gauss. After loading the cathode with Deuterium, Gold is co-deposited electrolytically on the cathode. When a coating of Gold is visible on the cathode, co-deposition is halted and the cathode is stimulated with a low-power laser with a maximum power of 30 milliwatts. The thermal response of the cathode is typically 500 mW with maximum output observed of approximately 1 watt. The effect is repeatable when protocols are followed and has been demonstrated in several laboratories."

The constant current and voltage, used by the authors, are typically 1A and 5V. They wait till the Pd cathode is loaded with deuterium and measure the temperature of the electrolyte after thermal equilibrium is established. The relationship between the input power (in this case 5000 mW) and the temperature is known from the "isoperibolic calibration" of the electolytic cell. The loaded cathode is then exposed to a laser beam, delivering only 30 mW of power, and the new, slightly higher equilibrium temperature is established. The observed temperature change, however, does not correspond to the input power of 30 mW, it corresponds to the power of, for example, 5500 mW. Excess power, for this numeric illustration, would be 470 mW. In other words, 5030 mW input (electric+light) and 5530 mW output (thermal). The ouput is nearly 10% hogher than the input. The excess energy, Q = 2.7*t=X joules (where t is the laser-exposure time is seconds) is very small but it is probably larger than in Galvani's experiments with frog's legs.

What is the origin of excess power? Without having any evidence that it comes from nuclear reactions I tend to suspect that it comes chemical reactions of some kind. Perhaps chemical energy was somehow stored in the cell during the period of loading palladium with deuterium and subsequently released under laser irradiation. I know that this kind of guessing in not original; speculations of that kind were advanced as soon as the discovery of cold fusion was announced. The authors specify that to load the cathode with deuterium the current of 0.1 A was flowing through the cell for 100 hours. After that the current was increased to 1 A for 24 hours. What evidence do the authors have that a

fraction of inputed energy could not possibly be accumulated, like in a car battery, before the laser beam was turned on?

I am not a chemist and I will not speculate about reactions that can conceivably be involved in the storage of energy. I would like to see the energy balance for the entire experiment. Was the average input power during the entire experiment, for example, in 100 +24 +3 = 127 hours, significantly smaller than the average output power for the same time interval? A positive answer to this difficult question, and absence of large experimental errors, would convince me that the energy storage during the loading of deuterium did not occur. On the other hand, as I indicated above, presence of nuclear reaction products, or nuclear particles, would by itself be sufficient to demonstrate that at least a fraction of excess power was nuclear. The situation seems to be the same as it was in 1989, except that the effect is said to be highly reproducible, at very low wattage levels. Is it a nuclear effect or is it a chemical effect? That is the main question.

In the section entitled "Results" the authors wrote: "It has been observed that a common red laser (30mW) when tuned to specific wavelengths appears to trigger a cathodic exothermic reaction 5-30 times greater than the magnitude of its radiant power output. The effect has not disappeared or diminished as calorimetric quality improved. It has also been observed that the magnitude of the thermal response of the cell may be altered by the polarization of the laser beam with respect to an external magnetic field." They do not speculate on the "nature of the cathodic exothermic reaction." They do not say that it might be nuclear. But the phrase "nuclear events" does appear in their papers. I will assume they think that the reactions are nuclear. The papers were presented at the cold fusion conference and "cold fusion" is often described as a new kind of nuclear reaction.

I suppose that better "calorimetric quality" refer to more accurate calorimetry. The numbers 5-30, on the other hand, refer to ratios of excess power over the laser beam power. These numbers show that small powers trigger releases of much larger powers. Let me turn to two other observations made in the paper: the effect of the magnetic field on the loading of deuterium into palladium, and the effect of polarization of laser light (with respect to the magnetic field) on excess power. In the section entitled "Experimental" that authors wrote: " We think the magnetic field improves the loading of deuterium." I suppose that the phrase "improves the loading" is meaningful to a chemist. The magnetic field strength, at the cathode submerged in the electrolyte, was 350 Gs. This is only several times larger than the terrestrial field. How can loading of deuterium be influenced by such field? How did the D/Pd ratio differ between loading with and without the magnetic field? These questions alone can become subject of a doctoral dissertation.

The same is probably true for the effect of light polarization. The section devoted to this subject begins with the following statement: "During the course of experimentation it was discovered that polarization of the laser beam can dramatically affect the thermal response of the cathode to the laser beam. Cravens observed during one of our runs that when the laser beam polarization is perpendicular to an external magnetic field, the thermal response of the cathode is maximized." I suppose that both authors observed the effect in subsequent experiments; a single observation of something unusual would not be trustworthy. The effect of polarization is described in the caption of Figures 10. It is difficult to understand this effect without first understanding the effect of the magnetic field on triggering excess energy. (It seems that the magnetic field plays a role not only in loading but also in what happens after loading.) Accepting experimental data, as reported on Figure 10, one has to face a difficult task of understanding what was going on.

Figure 11 introduces another complicating factor. "The cathode didn't respond well to the laser stimulation until the rare earth solution was added to the electrolyte. With the additive, the cathode became responsive to a laser operating at 657nm with a radiant output of 30 mW." The nature of that additive is not specified in the paper. In the caption of that figure the authors state that the "power to the cell was constant at 7 +/- .01 watts." That shows that the excess power was, at the highest point, equal to 10% of the input power. In the remaining part of this section the authors state that the effect was witnessed by four invited scientists. I do not think that this refers to the effect of polarization. It probably refers to the effect red light on the excess power (at constant polarization). For how long would the excess power be generated, after 2100 hours, if the laser beam was not turned of? My guess is that chemical reactions taking place in the cathode eventually destroy it. Is it possible that the observed excess heat is due to these reactions? Were the effects of polarized light on the yields of chemical reactions studied in other contexts? I do not know how to answer such questions.

The most recent paper of Letts and Cravens, as far as I know, was presented at the ASTI Conference in Italy (19-21 March 2004). The link to that document is available in

http://www.cerg.org/research/publications/index.html

The abstract is essentially the same as in the ICFF10 paper. Most of what I see in the last paper has already been communicated in the two papers to which I referred above. Graphical illustrations of seventeen cathode-preparation steps (previously described in words only) will certainly be appreciated by those who are interested in studying the unexplained Letts-Cravens effects. Some statements, however, are new. The authors wrote, "We did a series of experiments that replaced the LiOD with LiOH. It was clear that the LiOH did not yield any excess [energy]." That is a very significant experimental fact. They also wrote: "There seems to be a relationship between the temperature of the metal host lattice and the wavelength needed to trigger the effect..... There are runs where we see no excess [energy] until the correct wavelength [from a tunable laser] is reached. It is very reassuring to see excess heat response when the wavelength of the laser is altered by only a few nm. It is also hard to conceive of a calorimetric error that is so wavelength sensitive." I agree with this observation.

Referring to the effect of magnetic field on excess heat, and to the effect of polarization, the authors wrote: "Our better experiments have been with cathodes that were initially loaded in the presence of an external field. Often the excess heat is dependent on the relative angles between the linear polarized lasers and the direction of the magnetic field applied when the metal was first loaded. Again, it is hard to conceive of calorimetric errors that would change with the rotation of a laser outside the controlled environment or the insertion of a quarter wave optical plate in the beam. The maximum effect coincides with the E field of the polarized laser being perpendicular to the magnet field." This implies some kind of magnetically induced alignment on the cathode during its loading with deuterium. Was the magnet, located outside the electrolytic cell, removed after loading? I assume it was. The word "often" is reassuring; it shows that the effect of laser light polarization on the excess power was not a single observation.

The issue of nuclear versus non-nuclear origin of excess power was not addressed in this paper, except indirectly by telling us what happens when the LiOD electrolyte was replaced by LiOH electrolyte. Isotopic effect on chemical reactions, if any, are extremely small. Another issue that was not addressed has to do with duration of excess power runs. I would like to know, for example, why the laser had to be shut off after about 150 minutes in the experiment #560 (or after 3900 minutes in the experiment #587). I would also would like to know which "hidden variable" was responsible for the fluctuations of excess power (between 100 mW and 800 mW) in the experiment #587. The laser beam was presumably stable during the entire 5900 minutes interval.

I have no doubt that the authors are also interested in "hidden variables." Hopefully their more recent experiments will lead to better understanding of the cause-and-effect relations in this fascinating area of science. Asking questions is easy, answering them is much more difficult. Identification of hidden variables has been the major preoccupation of scientists involved in cold fusion experiments. The progress would be more rapid if the area was not declared to be pseudoscientific. Methods of validation used by individual researcher must always be questioned; condemning that entire field as pseudoscientific is not justifiable, in my opinion. Papers like those of Cravens and Letts should not be rejected by editors of mainstream journals; they should be allowed to undergo the usual pear review process. Financial support of research should be allocated to cold fusion researchers in the same way as in any other area of science. Will the situation change after the ongoing DOE investigation is over? I hope so.

170) Kanarev and Naudin

Ludwik Kowalski (9/2/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Here is the e-mail message received from Stefan Sundström in Sweden today: “Mr Kowalski: In your seeking for information on cold fusion, I recommend you to study the work of Mr. Kanarev. You can find and download his article and books on this site <http://kanarev.innoplaza.net/> I also recommend you to take a lock at the European patent data base . . .” The link brought P.M.Kanarev’s document entitled “Prof. Kanarev's View Point on the Energy Problem: WATER IS THE MAIN POWER CARRIER OF FUTURE POWER ENGINEERING.” The author seems to be a theoretical physicist from the Kuban State Agrarian University in Krasnodar, Russia. In the reply to Stefan I wrote: “I do not consider myself competent enough to deal scientifically with ‘the axiom of space - matter - time unity.’ But if you send me a short simplified essay on that subject, at the level accessible to high school physics teachers, I might post it on my web site.” I also asked about Stefan’s background and and about one particular claim made by Kanarev.

I suspect that the phrase “power carrier,” in the title of the article, is probably a poor translation of a Russian term for the “energy resource.” I am sure the author knows the difference between power and energy; he certainly does not think that power can be carried by a substance. By the way, it is not the first time that I see how a foreign author puts himself into unfavorable situation by posting a poorly translated article. Translational errors would most likely be corrected in a peer-reviewed article, published in a scientific journal. Quick publishing over the Internet is far from being perfect; it has many negative “side effects.”

The above was written in anticipation of an essay from Stefan. But the reply received today (9/3/04) did not contain an essay. He wrote: “I am not a scientist; I am a open minded family man. If we learn what energy is then we could tap on to something new, and do something better for our children.” In other words, he is layman aware of negative aspects of utilization of available energy resources. I understand frustration of people like him. He is desperate to hear about better alternatives.

His message contained the URL for the laboratory of Jean-Louis Naudin (in Paris) and a suggestion that students should study the description of French experiments on excess heat. I did correspond with Naudin last year but for some reason he stopped responding to my questions. I expected him to publish the fascinating results at the last International Conference on Cold Fusion (ICCF10) but he did not come. Will he come to the next conference, ICCF11, in Marseilles? I hope so. His results, described at

http://jlnlabs.imars.com/cfr/index.htm

are interesting. Naudin constructed a simple device, named cold fusion reactor (CFR) to generate excess power electrochemically. This URL shows results of numerous experiments designed to test reproducibility. He performed 32 such experiments and in all of them exit power was larger than input power, sometimes by the factor larger than two. Two other teams of researchers, one in the US and another in France, also confirmed generation of excess heat. In one case a toy engine was run on the excess power of the CFR.

I wish I were able to convince myself that the recorded excess power could not possibly be due to chemical reactions taking place inside the cells. Unfortunately, this possibility is not even mentioned. The name of the device, CFR, implies

nuclear origin of excess power and I expected to find a justification of such claim. That is why I was disappointed. But I was impressed by graphical illustrations and by simplicity of the apparatus. I plan to replicate his results as soon as a chemistry collaborator is found.

Naudin's document begins with a declaration: "I have used the experimental protocol fully described by Eugene F. Mallove at . Mallove, who died tragically this summer, was the editor of Infinite Energy magazine. I did fetch his description of the experimental protocol to which Naudin refers but found no discussion of chemical reactions. Why should I rule out a possibility that the excess heat is due to chemical reactions taking place inside the reactor? But, as said before, I am not a chemist. Perhaps what is not clear to me would be obvious to a chemist. Mallove wrote that the experiment "involves high-temperatures, high-voltages, explosive mixtures of oxygen and hydrogen, caustic solutions, and steam generation. .....It is visually and audibly spectacular -- brilliant glowing, pink, purple, lavender with white flashes on an underwater tungsten (W) electrode (e.g. 2 mm x 5 mm W foil or 1 cm x 1.6 mm diameter tungsten welding rod). A plasma-like underwater discharge on the electrode that often manages to disintegrate or melt tungsten underwater." Why should I exclude a possibility that some of the chemical reactions in CFR are exothermic? The current and voltage, in experiments described by Mallove, were 5 A and 180 V. No wonder that intensive underwater sparking and boiling takes place. I had a chance to experiment with similar underwater sparking two years ago but no calorimetric measurements were made.

Another thing that impressed me was that one of the teams that confirmed Naudin's findings consisted of highly trained electrochemist. On the other hand, I was slightly disappointed that the identity of the US laboratory, in which the confirming calorimetric experiments were conducted, was not specified. The document shows the photo of two researchers from Louisiana, and their names (two nice looking young girls, probably students), but not the name of the laboratory, or the name of the project director. Was it a high school project or a projects at a well known university? Such information is important when controversial results are presented. Why was it not provided by Naudin?

Before finishing this unexpected essay let me reflect on what came to my mind as I was reading Kanarev's paper again. I was thinking about similarities between his claims of Adamenko and those of Adamenko. Both scientists introduce themselves as theoretical physicists. Both refer to totally unheard off, and hard to believe, experimental results. Both are seeking foreign and domestic investors to support their projects. I suspect that these two people know each other very well. Perhaps they were working in the same Soviet laboratory about fifteen years ago; perhaps they learned physics from the same teachers. What a coincidence; I was informed about work of these scientists by strangers, and approximately at the same time (see unit #168).

Reading Kanarev's paper I was thinking about the Chinese scientist, Xing-liu Jiang, who wrote to me about zero point energy. This was described in my unit #162. After posting that, I asked the scientist to comment on what he wrote. He never did and I do not know why. Perhaps he expected me to be more knowledgeable in theoretical physics. Yes, my limitations prevent me from penetrating Kanarev's reasoning leading to new ways of obtaining energy from water. Perhaps a knowledgeable person will send me a simplified description of that reasoning. The best I can do is to show some quotes from Kanarev's paper:

"Problems of power engineering are well known. The power carriers, which are used nowadays, are not only exhaustible, but they cause a considerable damage to environment. Nearly 40 years ago it was announced that controlled thermonuclear fusion could be the future inexhaustible energy source. More than 25 billion dollars have been spent for the investigation of this source, but there is no positive result. This state can be explained by a considerable lag of theoretical investigations from the possibilities of industry to implement any installation in order to check an intuitive idea being formulated. As a result, the main attention has been paid to an *experiment*, not to a *theory*." What is wrong with using experimental evidence to validate theoretical anticipation?

"As there was no acceptable theoretical description of the planned process of thermonuclear fusion control, a positive result could be obtained only by chance. Theoretical prognostication of this result was impossible due to the absence of any notion concerning the models: the electron, the proton, the atom of hydrogen and the ions of chemical elements, which form plasma. Orthodox physics did not even set itself such task." My impression was that quantum mechanics, and quantum electrodynamics, made big progress in dealing with such topics.

“Modern industrial installations require 4 kWh for production of 1 cubic meter of hydrogen from water. When this hydrogen is burnt, 3.6 kWh of energy is released. If the energy expenses for production of hydrogen from water are reduced by twofold or threefold, it becomes a competitive energy carrier. If it is possible to reduce these expenses of hydrogen tenfold, it will become the cheapest energy carrier. In this case, coal, oil and natural gas fail to compete with it. Our investigations have shown that there are some plasma electrolytic devices and modes of their operation, which reduce energy expenses for obtaining one cubic meter of hydrogen up to 0.40 kWh. In this case, more than 1000% of additional energy is obtained. A laboratory device with such indices was made one year ago.”

The transition from a laboratory installation to the industrial one requires additional investigations with the use of rather expensive spectrometers, gas analyzers, electronic sets for simultaneous registration of more than 10 induces of the plasma electrolytic process. As hydrogen is an explosive gas, it is impossible to ignore the investigation stage for making the laboratory installation the industrial one. During the scale operation, dangerous radiations can take place, which accompany the transmutation process of the chemical element nuclei.

Five patents have been received for the investigation results; three positive decisions concerning the issue of the patents and three claims are in the process of consideration. Three editions of the book ‘*Water as a New Source of Energy*’ are available with the detailed theoretical description of plasma electrolysis of water and the quantitative calculations of the experimental results..... As the author has kept walking along the corridors of the Russian power without success for five years in order to get financing, the last hope remains – to find a foreign investor. The author is busy with this problem as it is clear that a delay in financing is equal to a loss of priority in this topical field of investigations, which solves two global problems of the mankind: the *energy problem* and the *environmental problem*.”

P.S. (9/26/04)
In Kanarev’s Page at I see some starnge phrases. On page 3, for example, I see “binding energy of the electron in the atomic nucleus” and “electron begins to absorb thermal photons.” On the next page I see “the proton should capture 2.531 electrons in order to become a neutron” and “particle ‘being dissolved’ in the ether.” Sentences in which these phrases appear might have some profound meaning to a theorist. But I am not a theorist. The ideas of electrons being captured by atomic nuclei, or being dissolved in the ether, are in conflict with what I know about nuclear phenomena. I hope someone more knowledgeable will comment on Kanarev’s project and ideas.

171) When will we hear from the DOE?

Ludwik Kowalski (9/4/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Do you remember the April, 2004, issue of Physics Today? It published a short article of Tont Feder entitled “DOE Warms to Cold Fusion. According to James Decker, deputy director of DOE's Office of Science, she wrote, a review of cold fusion will begin in the next month or so and it “won't take a long time--it's a matter of weeks or months.“ That was half a year ago; not much was written on the subject since that time. But, according to Justin Mullins article, in the September 2004 issue of IEEE Spectrum on Line,

http://www.spectrum.ieee.org/WEBONLY/resource/sep04/0904nfus.html

“Later this month, the U.S. Department of Energy will receive a report from a panel of experts on the prospects for cold fusion -- the supposed generation of thermonuclear energy using tabletop apparatus.” I would like to thank Steven Krivit for informing me about this paper yesterday. The Internet search engine tells me that Justin Mullins is a science journalist and one of the editors of New Science. But is he the author of the IEEE piece? I do not know; perhaps it is somebody else with the same name. And how does he know that the panel report will be ready this month? I asked Steven this question. The answer was: “He doesn't KNOW, but is guessing. According to information I have heard from insiders, his guess is accurate.” I know, from one of the participants, that the panel review took place on August 23 and 24. But I have no idea when will the report be released.

I hope that the panel will look upon cold fusion as a set of interesting scientific claims; looking at it as a technology for “generation of thermonuclear energy using tabletop apparatus,” as described by Mullin, would be totally unjustified at this time. My Letter to the Editor of Physics Today (just published in the September, 2004, issue), focuses on that topic. Here is the content of my letter:

“As a physics teacher who is uncertain how to answer students' questions about cold fusion, I welcome the upcoming US Department of Energy investigation of recent claims in this controversial area. I agree with Toni Feder (Physics Today, April 2004, page 27) that "skepticism about the credibility and reproducibility of cold fusion remains widespread."

I have some questions I'd like to see the DOE investigators answer. Is it true that unexpected emission of neutrons, protons, tritons, and alpha particles (at rates significantly above the background) has been observed in several cold fusion experiments? Has accumulation of helium-4, at the rate of about one atom per 24 MeV of excess heat, been confirmed by many scientists, as reported by electrochemist Michael McKubre in Feder's story? Have highly abnormal isotopic ratios been found in some cold fusion setups? Is there any indication that leading cold fusion scientists are incompetent or that their data are fraudulent? Is the research methodology that cold fusion scientists use different from that used in other areas of physical science? Answers to these questions will help me decide what to think about cold fusion and what to tell students about it.

Speculations about practical applications of new findings should be de-emphasized at this time. They will emerge naturally when basic scientific claims are recognized as valid and when researchers in cold fusion are no longer treated as if they were con artists and charlatans. The "chilling effect" mentioned by Randall Hekman in the Physics Today story prevents young scientists from entering the area of cold fusion research. I also agree with chemist Allen Bard that being able to reproduce experimental results is not good enough; it is only a preliminary step. But wasn't poor

reproducibility the central point of criticism when cold fusion was first investigated 15 years ago? In my opinion, experimental claims should not be disqualified solely on reproducibility; validation should depend on credentials of researchers and, above all, on methodologies they used in particular experiments. “

I was very surprised that my letter to the editor was not “one of many.” Does it mean that nobody else reacted to Feder’s article? That is not likely to be the case. In the e-mail message the editor wrote to me that they expect to have a “lively discussion” on the subject and that several letters had already been accepted. The implication was that my letter will not be in the first bunch to be published. And then, at the end of July, I was informed that my letter was accepted. I was also given an opportunity to revise the letter. The last sentence was added at this time. I was tempted to add more but was afraid that this might delay the publication. What happened? Why other letters were not published at the same time?

My guess is that they received many letters that will appear in the next issue. My letter was probably chosen because it shows no bias toward or against cold fusion. It could be published alone without giving preference to one point of view or another. Other contributors will probably be made by active research scientists; I am eager to read them and to learn from them. I am happy that my letter was published at this time; perhaps it will be taken seriously by the members of the panel investigating cold fusion.

Let me end this short essay with some extracts from Feder’s article. Referring to her interview with Decker she quotes him: “Whether or not it has applications to the energy business is clearly unknown at this point, but you need to sort out the science before you think about applications." Is this an indication that the panel will focus on science and not on science fiction? I hope so. Referring to a excess power she wrote: "We know that this has economic implications and, potentially, security implications. The main application that cold fusion enthusiasts foresee following from their work is a clean source of energy; transmutation of nuclear waste and tritium production to augment weapons are also on their list.” It is difficult to be an enthusiast and not to allow the enthusiasm to interfere with objectivity.

As I wrote before, appearance of excess power per se is not an indication that nuclear energy is involved. The only way to make excess power relevant, in the contest of cold fusion, is to focus on the associated accumulation of reaction products. Many cold fusion researchers are fully aware of this. Contrary to initial expectations radioactive byproducts, if any, are not always dominant. That makes their identification difficult when the amounts of released energy are small. Another difficulty has to do with the possible “electric battery” effects. How do we know that a positive excess power, observed in a later part of an experiment, is not accompanied by an earlier negative excess? By negative excess power I mean some kind of storage of supplied energy, for example, in a chemical compound. Both difficulties were recognized when the discovery of cold fusion was announced in 1989.

Some theoretical physicists (see units #162, #168 and #170) try to bypass the difficulties by postulating that excess power can come from nowhere. They speculate about the so-called “zero point energy of vacuum” without performing experiments to validate such ideas. I am neither qualified nor ready to defend this approach. In my opinion, the panel of scientists investigation cold fusion should focus on claims supported by experimental evidence. Theoretical models are important components of our understanding of nature but focusing on them at this time, in the highly controversial area of excess power, seems to be premature. Discussion involving theoretical models will develop spontaneously after the reality of at least one experimental claim is recognized. A panel-investigation approach to a scientific controversy is highly unusual; in this case it is needed to correct the effect of an error made fifteen years ago. The main purpose should be to establish normality not to make a definite pronouncement about a set of claims.

A recent overview of cold fusion, by a scientist: Edmund Storms, was submitted to the panel of experts appointed by the DOE to reevaluate cold fusion. The reevaluation, as indicated by Storms, started on August 23, 2004. To see his overview go to:

<http://lenr-canr.org>

and scroll down to the link “Why I believe 'Cold Fusion' is Real.” Click on that link and the pdf file containing the paper will be downloaded to your computer. It is interesting that neither zero point energy nor hydrinos are mentioned. This confirms what I wrote about these fields; they are not part of cold fusion. Let me pause now. Additional paragraphs are likly to be appended to this essay in coming weeks. They will focus on the expected “lively discussion” triggered by the

DOE initiative, and by Feder's article.

172) Items for student projects

Ludwik Kowalski (9/9/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Browsing the Internet I discovered a student-oriented item on cold fusion. The URL for this item is:

http://www.all-science-fair-projects.com/science_fair_projects_encyclopedia/Cold_fusion

I am posting its content here because I do not know how permanent this Internet item will be. The Science Fair Projects Encyclopedia, whose URL is:

http://www.all-science-fair-projects.com/science_fair_projects_encyclopedia/Main_Page_asfp

seems to be a good resource to start learning about a subject. Here is a list of main topics in the area of physics and chemistry.

* **Physics**
* Acoustics
* Astronomy
* Astrophysics
* Atomic, Molecular, and Optical physics
* Biophysics
* Computational physics
* Condensed matter physics
* Cryogenics
* Electronics
* Engineering
* Fluid dynamics
* Polymer physics
* Optics
* Materials physics
* Mathematical physics
* Nuclear physics
* Plasma physics
* Particle physics (or High Energy Physics)
* Vehicle dynamics

* **Chemistry**
* Censored page
* Biochemistry
* Computational chemistry
* Electrochemistry
* Inorganic chemistry
* Materials science

* Organic chemistry
* Physical chemistry
* Quantum chemistry
* Spectroscopy
* Stereochemistry
* Thermochemistry

Other areas, such as Biology or Computer Science, offer similar links to start searching. To find the link to cold fusion I clicked on “Nuclear physics”, then on “Fusion.” The link was found at the bottom of that item. A student who does not know how to search by categories can find an item of interest by typing it in the search box. I typed “cold fusion” (must be without quotation marks) and the item appeared.

That particular item was “last updated” on 9/2/2004. In trying to locate the author I found the following: “The content of each page in our Encyclopedia section originates from a corresponding web page at Wikipedia.org and is licensed for use under the terms of the GNU Free Documentation License. The source web page can be accessed by going to http://en.wikipedia.org/wiki/[heading of the relevant encyclopedia page]. For example, if you are at viewing a page in our Encyclopedia with the heading "Biology", you can go to the origin of this content at Wikipedia.org by pointing your browser to http://en.wikipedia.org/wiki/biology. There, you will be able to view the original content and may be able to participate in editing such content . . . “

Aha, Wikopedia! That is an online encyclopedia in which anybody can change anything. Several weeks ago I added a sentence to one items because I felt that it was important. A week later that item was removed by somebody who did not like it. My sentence was replaced by something else. The authors of posted items have not be selected on the basis of their competence, and the content has not been screened for accuracy by recognized experts. Therefore students should be advised to verify the content by going to more reliable sources. The underlined words and phrases were links in the original; they are no longer links in my pasted text below.

Cold fusion

Cold fusion is a nuclear fusion reaction that occurs well below the temperature required for thermonuclear reactions (millions of degrees Celsius). Such reactions may occur near room temperature and atmospheric pressure, and even in a relatively small (table top) experiment. In a narrower sense, "cold fusion" also refers to a particular type of fusion presumably occurring in electrolytic cells.

The term "cold fusion" was coined by Dr Paul Palmer of Brigham Young University in 1986 in an investigation of "geo-fusion", or the possible existence of fusion in a planetary core. It was brought into popular consciousness by the controversy surrounding the Fleischmann-Pons experiment in March of 1989. A number of other scientists have reported replication of their experimental observation of anomalous heat generation in electrolytic cells, but in a non-predictable way, and most scientists believe that there is no proof of cold fusion in these experiments. A majority of scientists consider this research to be pseudoscience, while proponents argue that they are conducting valid experiments in a protoscience that challenges mainstream thinking.

The subject has been of scientific interest since nuclear fusion was first understood. Hot nuclear fusion using deuterium yields large amounts of energy, uses an abundant fuel source, and produces only small amounts of manageable waste; thus a cheap and simple process of nuclear fusion would have great economic impact. Unfortunately, no experiments have yet been able to show both a "cold" fusion reaction and a large net release of energy over the whole experiment.

Table of contents [showhide]

History of cold fusion by electrolysis

Early work

The idea that palladium or titanium might catalyze fusion stems from the special ability of these metals to absorb large quantities of hydrogen (including its deuterium isotope), the hope being that deuterium atoms would be close enough together to induce fusion at ordinary temperatures. The special ability of palladium to absorb hydrogen was recognized in the nineteenth century. In the late nineteen-twenties, two German scientists, F. Paneth and K. Peters, reported the transformation of hydrogen into helium by spontaneous nuclear catalysis when hydrogen is absorbed by finely divided palladium at room temperature. These authors later acknowledged that the helium they measured was due to background from the air.

In 1927, Swedish scientist J. Tandberg said that he had fused hydrogen into helium in an electrolytic cell with palladium electrodes. On the basis of his work he applied for a Swedish patent for "a method to produce helium and useful reaction energy". After deuterium was discovered in 1932, Tandberg continued his experiments with heavy water. Due to Paneth and Peters' retraction, Tandberg's patent application was denied eventually.

Pons and Fleischmann's experiment

On March 23, 1989, chemists Stanley Pons and Martin Fleischmann ("P and F") at the University of Utah held a press conference and reported the production of excess heat that could only be explained by a nuclear process. The report was particularly astounding given the simplicity of the equipment, just a pair of electrodes connected to a battery and immersed in a jar of heavy water (dideuterium oxide). The press reported on the experiments widely, and it was one of the front-page items on most newspapers around the world. The immense beneficial implications of the Utah experiments, if they were correct, and the ready availability of the required equipment, led scientists around the world to attempt to repeat the experiments within hours of the announcement.

The press conference followed about a year of work of increasing tempo by Pons and Fleischmann, who had been working on their basic experiments since 1984. In 1988 they applied to the US Department of Energy for funding for a larger series of experiments: up to this point they had been running their experiments "out of pocket".

The grant proposal was turned over to several people for peer review, including Steven Jones of Brigham Young University. Jones had worked on muon-catalyzed fusion for some time, and had written an article on the topic entitled *Cold Nuclear Fusion* that had been published in Scientific American in July 1987. He had since turned his attention to the problem of fusion in high-pressure environments, believing it could explain the fact that the interior temperature of

the Earth was hotter than could be explained without nuclear reactions, and by unusually high concentrations of Helium-3 around volcanoes that implied some sort of nuclear reaction within. At first he worked with diamond anvils, but had since moved to electrolytic cells similar to those being worked on by Pons and Fleischmann, which he referred to as *piezonuclear fusion*. In order to characterize the reactions, Jones had spent considerable time designing and building a neutron counter, one able to accurately measure the tiny numbers of neutrons being produced in his experiments.

Both teams were in Utah, and met on several occasions to discuss sharing work and techniques. During this time Pons and Fleischmann described their experiments as generating considerable "excess energy", excess in that it could not be explained by chemical reactions alone. If this were true, their device would have considerable commercial value, and should be protected by patents. Jones was measuring neutron flux instead, and seems to have considered it primarily of scientific interest, not commercial. In order to avoid problems in the future, the teams *apparently* agreed to simultaneously publish their results, although their accounts of their March 6th meeting differ.

In mid-March both teams were ready to publish, and Fleischmann and Jones were to meet at the airport on the 24th to both hand in their papers at the exact same time. However Pons and Fleischmann then "jumped the gun", and held their press conference the day before. Jones, apparently furious at being "scooped", faxed in his paper to *Nature* as soon as he saw the press announcements. Thus the teams both rushed to publish, which has perhaps muddied the field more than any scientific aspects.

Within days scientists around the world had started work on duplications of the experiments. On April 10th a team at Texas A&M University published results of excess heat, and later that day a team at the Georgia Institute of Technology announced neutron production. Both results were widely reported on in the press. Not so well reported was the fact that both teams soon withdrew their results for lack of evidence. For the next six weeks competing claims, counterclaims, and suggested explanations kept the topic on the front pages, and led to what writers have referred to as "fusion confusion."

In mid-May Pons received a huge standing ovation during a presentation at the American Chemical Society. The same month the president of the University of Utah, who had already secured a $5 million commitment from his state legislature, asked for $25 million from the federal government to set up a "National Cold Fusion Institute". On May 1st a meeting of the American Physical Society held a session on cold fusion that ran past midnight; a string of failed experiments were reported. A second session started the next evening and continued in much the same manner. The field appeared split between the "chemists" and the "physicists".

At the end of May the Energy Research Advisory Board (under a charge of the US Department of Energy) formed a special panel to investigate cold fusion. The scientists in the panel found the evidence for cold fusion to be unconvincing. Nevertheless, the panel was "*sympathetic toward modest support for carefully focused and cooperative experiments within the present funding system*". [1] http://www.ncas.org/erab/sec5.htm

Both critics and those attempting replications were frustrated by what they said was incomplete information released by the University of Utah. With the initial reports suggesting successful duplication of their experiments there was not much public criticism, but a growing body of failed experiments started a "buzz" of their own. Pons and Fleischmann later apparently claimed that there was a "secret" to the experiment, a statement that infuriated the majority of scientists to the point of dismissing the experiment out of hand.

By the end of May much of the media attention had faded. This was due not only to the competing results and counterclaims, but also to the limited attention span of modern media. However, while the research effort also cooled to some degree, projects continued around the world.

Experimental set-up and observations

In their original set-up, Fleischmann and Pons used a Dewar flask (a double-walled vacuum flask) for the electrolysis, so that heat conduction would be minimal on the side and the bottom of the cell (only 5 % of the heat loss in this experiment). The cell flask was then submerged in a bath maintained at constant temperature to eliminate the effect of

external heat sources. They used an open cell, thus allowing the gaseous deuterium and oxygen resulting from the electrolysis reaction to leave the cell (with some heat too). It was necessary to replenish the cell with heavy water at regular intervals. The cell was tall and narrow, so that the bubbling action of the gas kept the electrolyte well mixed and of a uniform temperature. Special attention was paid to the purity of the palladium cathode and electrolyte to prevent the build-up of material on its surface, especially after long periods of operation.

The cell was also instrumented with a thermistor to measure the temperature of the electrolyte, and an electrical heater to generate pulses of heat and calibrate the heat loss due to the gas outlet. After calibration, it was possible to compute the heat generated by the reaction.

A constant current was applied to the cell continuously for many weeks, and heavy water was added as necessary. For most of the time, the power input to the cell was equal to the power that went out of the cell within measuring accuracy, and the cell temperature was stable at around 30 °C. But then, at some point (and in some of the experiments), the temperature rose suddenly to about 50 °C without changes in the input power, for durations of 2 days or more. The generated power was calculated to be about 20 times the input power during the power bursts. Eventually the power bursts in any one cell would no longer occur and the cell was turned off.

Continuing efforts

There are still a number of people researching the possibilities of generating power with cold fusion. Scientists in several countries continue the research, and meet at the International Conference on Cold Fusion (see Proceedings at www.lenr-can.org http://www.lenr-canr.org/index.html)

The generation of excess heat has been reported by

Michael McKubre, Center at Stanford Research International,
Richard A. Oriani (University of Minnesota, in Dec 90),
Robert A. Huggins (at Stanford University in March 90), and
Y. Arata (Osaka University, Japan)

among others. In the best experimental set-up, excess heat was observed in 50% of the experiment reproductions. Various fusion ashes and transmutations were observed by some scientists.

Dr. Michael McKubre thinks a working cold fusion reactor is possible. Dr. Edmund Storms, a former scientist with The Los Alamos National Laboratory in New Mexico, maintains an international database of research into cold fusion.

In March 2004 the US Department of Energy decided to review all previous research of cold fusion in order to see whether further research was warranted by any new results.

Arguments in the controversy

A majority of scientists consider current cold fusion research to be pseudoscience, while proponents argue that they are conducting valid experiments that challenge mainstream science. (see history of science and technology). Here are the main arguments in the controversy.

Reproducibility of the result

While some scientists have reported to have reproduced the excess heat with similar or different set-ups, they could not do it with predictable results, and many others failed. Some see this as a proof that the experiment is pseudoscience.

While the experiment would indeed be more convincing if it were reproducible by simply following a recipe, or if the power generation was continuous instead of sporadic, it is not uncommon for a new phenomenon to be difficult to control, and to bring erratic results. For example attempts to repeat electrostatic experiments (similar to those performed

by Benjamin Franklin) often fail due to excessive air humidity. That does not mean that electrostatic phenomena are fictitious, or that experimental data are fraudulent. Occasional observations of new events, by qualified experimentalists, can be preliminary steps leading to recognized discoveries.

Most scientists doubt this is one of those cases, however, due to the fact that many experiments have been done in the 15 years since the 1989 announcements, and experimental results continue to be erratic, unconvincing, and poorly understood. Recent experimental results, on the other hand, are much less erratic than 15 years ago. Steven Jones, for example, reported (in 2003) that unexpected neutrons and charged particles, from TiDx, are observed in approximately 70% of experiments. Criticism of experimental data should not be based on reproducibility, it should be based on credentials of researchers and, above all, on examination of methodologies they use in particular investigations. An experimental claim, however, can not be taken for granted without one hundred percent reproducibility.

Current understanding of nuclear process

The DOE panel says: "*Nuclear fusion at room temperature, of the type discussed in this report, would be contrary to all understanding gained of nuclear reactions in the last half century; it would require the invention of an entirely new nuclear process*".

However, this argument only says that the experiment has unexplained results, not that the experiment is wrong. As an analogy, superconductivity was observed in 1911, and explained theoretically only in 1957.

Current understanding of hot nuclear fusion shows that the following explanations are not adequate:

* Nuclear reaction in general: The average density of deuterium in the palladium rod seems vastly insufficient to force pairs of nuclei close enough for fusion to occur according to mechanisms known to mainstream theories. The average distance is approximately 0.17 nanometers, a distance at which the attractive strong nuclear force cannot overcome the Coulomb repulsion. Actually, deuterium atoms are closer together in D2 gas molecules, which do not exhibit fusion.

* Absence of standard nuclear fusion products: if the excess heat were generated by the fusion of 2 deuterium atoms, the most probable outcome would be the generation of either a tritium atom and a proton, or a ^{3}He and a neutron. The level of neutrons, tritium and ^{3}He actually observed in Fleischmann-Pons experiment have been well below the level expected in view of the heat generated, implying that these fusion reactions cannot explain it.

* Fusion of deuterium into Helium 4: if the excess heat were generated by the hot fusion of 2 deuterium atoms into ^{4}He, a reaction which is normally extremely rare, gamma rays and Helium would be generated. Again, insufficient levels of Helium and gamma rays have been observed to explain the excess heat, and there is no known mechanism to explain how gamma rays could be converted into heat.

Energy source vs power store

While the output power is higher than the input power during the power burst, the power balance over the whole experiment does not show significant imbalances. Since the mechanism under the power burst is not known, one cannot say whether energy is really produced, or simply stored during the early stages of the experiment (loading of deuterium in the Palladium cathode) for later release during the power burst.

A "power store" discovery would have much less value than an "energy source" one, especially if the stored power can only be released in the form of heat.

Other kinds of fusion

This article focuses on fusion in electrolytic cells. Other forms of fusion have been studied by scientists. Some are "cold" in the sense that no part of the reaction is actually hot (except for the reaction products), some are "cold" in the sense that the energies required are low and the bulk of the material is at a relatively low temperature, and some are

"hot", involving reactions which create macroscopic regions of very high temperature and pressure.

Locally cold fusion :

* Muon-catalyzed fusion is a well-established and reproducible fusion process which occurs at low temperatures. It has been studied in detail by Steven Jones in the early 1980's. Because of the energy required to create muons, it is not able to produce net energy.

Generally cold, locally hot fusion :

* In Cluster impact fusion , microscopic droplets of heavy water (on the order of 100-1000 molecules) are accelerated to collide with a target, so that their temperature at impact reaches at most 10^5 Kelvin, 10,000 times smaller than the temperature required for hot fusion. In 1989, Friedlander and his coworkers observed 10^{10} more fusion events than expected with standard fusion theory. Recent research ([2] http://arxiv.org/abs/nucl-th/0304066) suggests that the calculation of effective temperature may have failed to account for certain molecular effects which raise the effective collision temperature, so that this is a microscopic form of hot fusion.

* In sonoluminescence, acoustic shock waves create temporary bubbles that collapse shortly after creation, producing very high temperatures and pressures. In 2002, Rusi P. Taleyarkhan explored the possibility that bubble fusion occurs in those collapsing bubbles. If this is the case, it is because the temperature and pressure are sufficiently high to produce hot fusion.

* The Farnsworth-Hirsch Fusor is a tabletop device in which fusion occurs. This fusion comes from high effective temperatures produced by electrostatic acceleration of ions. The device can be built inexpensively, but it too is unable to produce a net power output.

* Antimatter-catalyzed fusion uses small amounts of antimatter to trigger a tiny fusion explosion. This has been studied primarily in the context of making nuclear pulse propulsion feasible.

Hot fusion :

* "Standard" fusion, in which the fuel reaches tremendous temperature and pressure inside a fusion reactor, nuclear weapon, or star.

Several of these systems are "nonequilibrium systems", in which very high temperatures and pressures are produced in a relatively small region adjacent to material of much lower temperature. In his doctoral thesis for MIT, Todd Rider did a theoretical study of all non-equilibrium fusion systems. He demonstrated that all such systems will leak energy at a rapid rate due to Bremsstrahlung, radiation produced when electrons in the plasma hit other electrons or ions at a cooler temperature and suddenly decelerate. The problem is not as pronounced in a hot plasma because the range of temperatures, and thus the magnitude of the deceleration, is much lower.

References

Popular accounts of the controversy

Robert L. Park (2000) gives a thorough account of cold fusion and its history which represents the perspective of the mainstream scientific community. Two other sceptical books from the scientific mainstream are those by Frank Close (1992) and John Huizenga (1992). Huizenga was co-chair of the DOE panel set up to investigate the Pons/Fleischmann experiment, and his book is perhaps the definitive account of the cold fusion affair.

Eugene Mallove's *Fire from Ice* (1991) is an early account from the pro-cold-fusion perspective. Charles Beaudette 's *Excess heat* (2000) is a more recent scientific account of why cold fusion research prevailed.

173) Pseudoscience in Wikopedia

Ludwik Kowalski (9/10/04)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

As I indicated in item #172, there is an interesting creature on the Internet, an online encyclopedia that is editable. If you do not like something you can simple delete it, or replace it with something else, or add a comment, etc. etc. It is called “Wikipedia, the free encyclopedia.” To learn more about this creature go to:

http://en.wikipedia.org/wiki/Main_Page
http://en.wikipedia.org/wiki/Wikipedia:Welcome%2C_newcomers

Here is an item on pseudoscience that I found in Wikopedia. The issues of protoscience and pseudoscience belong to philosophy, like the issue of the so-called “scientific method.” But they are certainly worth discussing with students. That is my justification for posting the piece below.

Pseudoscience

From Wikipedia, the free encyclopedia.

A **pseudoscience** is any body of knowledge purporting to be either both factual and scientific, or of an even higher standard of knowledge , but which fails to comply with scientific method.

Motivations for the advocacy or promotion of pseudoscience range from simple naivety about the nature of science or of the scientific method, to deliberate deception for financial or other benefit. Some people consider some or all forms of pseudoscience to be harmless entertainment. Others, such as Richard Dawkins , consider all forms of pseudoscience to be harmful, whether or not they result in immediate harm to their followers.

Table of contents [hide]

[edit]

Classifying Pseudoscience

Typically, pseudoscience fails to meet the criteria met by science generally (including the scientific method), and can be identified by a combination of these characteristics:
by asserting claims without supporting experimental evidence;
by asserting claims which contradict experimentally established results;
by failing to provide an experimental possiblity of reproducible results;
by asserting claims that violate falsifiability ; or
by violating Occam's Razor (the principle of choosing the simplest explanation when multiple viable explanations are possible); the more egregious the violation, the more likely.

Pseudoscience is distinguishable from revelation, theology or spirituality in that it claims to offer insight into the physical world by "scientific" means (i.e., most usually in accordance with the scientific method). Systems of thought that rely upon "divine" or "inspired" knowledge are not considered pseudoscience if they do not claim to be scientific or to overturn well established science.
[edit]

Pseudoscience Contrasted with Protoscience

Pseudoscience also differs from protoscience . The latter may be defined as speculation or hypothesis which has not yet been tested adequately by the scientific method, but which is otherwise consisent with existing science or which, where inconsistent, offers reasonable account of the inconsistency. Pseudoscience, in contrast, is characteristically wanting adequate tests or the possibility of them, occasionally untestable in principle, and its supporters are frequently strident in insisting that existing scientific results are wrong. Pseudoscience is often unresponsive to ordinary scientific procedures (e.g., peer review, publication in standard journals). In some cases, no one applying scientific methods could disprove a pseudoscientific hypothesis (i.e. untestable claims) and failure to do so is often cited as evidence of the truth of the pseudoscience.

The boundaries between pseudoscience, protoscience, and "real" science are often unclear to non-specialist observers. They can even be obscure to experts. Many people have tried to offer objective criteria for the term, with mixed success. Often the term is used simply as a pejorative to express the speaker's low opinion of a given field, regardless of any objective measures.

If the claims of a given pseudoscience can be experimentally tested it may be real science, however odd, astonishing, or intuitively acceptable. If they cannot be tested, it is likely pseudoscience. If the claims made are inconsistent with existing experimental results or established theory, it is often presumed to be pseudoscience. Conversely, if the claims of any given "science" cannot be experimentally tested it may not be a real science, however odd, astonishing, or intuitively acceptable.

In such circumstances it may be difficult to distinguish which of two opposing "sciences" are valid; for example, both the proponents and opponents of the Kyoto Protocol on global warming have recruited the help of scientists to endorse contradictory "scientific" positions, because of differing political goals. This

enlistment of science in the service of politics is sometimes called " junk science ".

Such fields as acupuncture and lucid dreaming may be categorized as protosciences; there is a reasonable expectation that as they are experimentally examined, they may produce some scientifically valid results. They are, at least, accessible to experimental examination.
[edit]

The Problem of Demarcation

After more than a century of active dialogue, the question of what marks the boundary of science remains fundamentally unsettled. As a consequence the issue of what constitutes pseudoscience continues to be controversial. Nonetheless, reasonable consensus exists on certain sub-issues. Criteria for demarcation have traditionally been coupled to one philosophy of science or another. Logical positivism , for example, espoused a theory of meaning which held that only statements about empirical observations are meaningful, effectively asserting that statements which are not derived in this manner (including all metaphysical statements) are meaningless. Later, Karl Popper attacked logical positivism and introduced his own criterion for demarcation, falsifiability . This in turn was criticised by Thomas Kuhn , and also by Popper supporter Imre Lakatos who proposed his own criteria that distinguished between progressive and degenerative research programs.
[edit]

Kuhn and paradigm shifts

Thomas Kuhn , an American historian of science , has proven very influential in the philosophy of science , and is often connected with what has been called postpositivism or postempiricism . In his 1962 book The Structure of Scientific Revolutions , Kuhn divided the process of doing science into two different endeavors, which he called **normal science** and **extraordinary science** . The process of "normal" science is what most scientists do while working within the current accepted paradigm of the scientific community, and within this context Karl Popper 's ideas on falsification as well as the idea of a scientific method still have some currency. This sort of work is what Kuhn calls "problem solving": working within the bounds of the current theory and its implications for what sorts of experiments should or should not be fruitful. However, during the process of doing "normal" science, Kuhn claimed, anomalies are generated, some of which lead to an extension of the dominant paradigm in order to explain them (like the idea of punctuated equilibrium within the paradigm of evolution), and others for which no satisfactory explanation can be found within the current paradigm.

When enough of these anomalies have accumulated, and scientists within the field find them significant (often a very subjective judgment), a "crisis period" is began, and some scientists begin to participate in the activity of "extraordinary" science. In this phase, it is recognized that the old paradigm is fundamentally flawed and cannot be adapted to further use, and totally new (or often old and abandoned) ideas are looked at, most of which will be failures. But during this time, a new paradigm is created, and after a protracted period of " paradigm shift ," the new paradigm is accepted as the norm by the scientific community and integrated into their previous work, and the old paradigm is banished to the history books. The classic example of this is the shift from Maxwellian /Newtonian physics to Einsteinian /Quantum physics in the early 20th century . If the acceptance or failure of scientific theories relied simply on simple falsification,

according to Kuhn, then no theory would ever survive long enough to be fruitful, as all theories contain anomalies.

The process by which Kuhn says a new paradigm is accepted by the scientific community at large does indicate one possible demarcation between science and pseudoscience. Richard J. Bernstein reads Kuhn as saying that a new paradigm is accepted mainly because it has a superior ability to solve problems that arise in the process of doing normal science. That is, the value of a scientific paradigm is its predictive power and its ability to suggest naturalistic solutions to new problems while continuing to satisfy all of the problems solved by the paradigm that it replaces. Pseudoscience can then be said to be demarcated by a failure to provide such naturalistic explanations, which leads to the labeling of any theory represented as science and appealing to metaphysical explanations for natural phenomena as a pseudoscientific idea.
[edit]

Feyerabend and the problem of autonomy in science

There has been a post-Kuhn trend to downplay the difference between science and pseudoscience, as Kuhn's work largely called question to the Popperian ideal of simple demarcation, and emphasized the human, subjective quality of scientific change. The radical philosopher of science Paul Feyerabend went so far as to claim that there can be found no method within the history of scientific practice which has not been violated at some point in the advancing of scientific knowledge. Both Lakatos and Feyerabend suggest that science is not an autonomous form of reasoning, but is inseparable from the larger body of human thought and inquiry. If so, then the questions of truth and falsity, and correct or incorrect understanding are not uniquely empirical. Many meaningful questions can not be settled empirically -- not only in practice, but in principle.

The problem of demarcation is considered solved by some, for others there is no such thing as an autonomous scientific method , no definitive philosophy of science and no clear and agreed-upon distinction between science and pseudoscience.
[edit]

Examples of Pseudoscience

Main article :List of alternative, speculative and disputed theories

Examples of fields of endeavor that many consider -- to varying extents -- pseudoscientific include Cold fusion, pseudoarchaeology, Gene Ray 's Time Cube, astrology and homeopathy . Pseudoscientific science and medical practices are often quite popular. Medical pseudosciences even sometimes show notable theraputic benefits, possibly due to the placebo effect or observer bias. Many pseudosciences are associated with the New Age movement and there is a tendency to improperly associate all practices of the "New Age" with pseudoscience.

There are also young fields of science that are sometimes frowned upon by scientists from established fields, primarily because they are speculative in nature:
exobiology /astrobiology

Search for Extraterrestrial Intelligence (SETI)
Communication with Extraterrestrial Intelligence (CETI)

These fields are not considered pseudoscientific or protoscientific by most scientists, though, and they are studied at many universities and specialized institutes. SETI and CETI advocates do generally not claim that extraterrestrials exist, although most consider the possibility likely (see Drake equation). There is controversy in biology about whether evidence of extraterrestrial microbial life has been found (fossilized in meteorites and as part of the Viking program 's exobiology experiments).

Certain "watchdog" groups, such as CSICOP , have released statements expressing concern about the apparent growing popularity of pseudoscience, especially when it applies to scientific fields that are intended to save people's lives. A number of self-proclaimed alternative medicine treatments have been designated pseudoscience by critics, largely because some of these methods inspire false hope in terminally ill patients, and end up costing large amounts of money without actually providing any real benefit, treatment, or cure for various ailments.
[edit]

Non-Pseudoscience Nonsense

There is a subset of what is often called pseudoscience which differs from what has been here termed pseudoscience. Most of these are mathematically based, and the problems are often phrased with tempting simplicity. They often live in a closed system of assumptions and premises, and depend on a faulty interpretation of the rules of that system. While pseudosciences have merely failed to prove themselves true, these undertakings can be proven impossible.

The ancient geometric problems of trisecting an angle using only a straightedge and compass , and of drawing a square with the same area as a given circle (or " squaring the circle ") are examples of this kind of problem. Some say that the inventions purporting to illustrate perpetual motion also fall into this group. The latter appears with such frequency that the U. S. Patent Office has a policy not to consider patent applications of this sort (see perpetual motion for more information).

Because its success does not depend on empirical evidence from the "real" world, some scientists do not consider mathematics to be a science. In that context a violation of the rules of mathematics cannot be pseudoscience. Those scientists who are mathematicians however, would say instead that the correct technical term for something violating the rules of mathematics would be 'wrong'. Mathematics differs from the other sciences in that it is based on proof , which (mathematicians say) provides a much higher degree of certainty than can be afforded by experiment (though some experimentalists disagree).

174) Naudin's Excess power

Ludwik Kowalski (September 11, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Highly impressive findings of Jean-Louis Naudin have been reported more that one year ago, as described in unit #73. In reading this unit again I see that something very important was not emphasized. Naudin's experiments use ordinary water and they generate excess powers of hundreds of watts. This can be contrasted with excess powers smaller than one watt reported to be reproducible by other electrochemists. In one case the input was 1200 W input while the output was 3093 W output. The excess power of 1893 W simplifies calorimetric measurements; the amount of generated heat is calculated from the amount of evaporated water. (If the value of 3093 W were calculated from the weight of lost water then the true excess power would be even larger because some excess heat is likely to be lost through convection and conduction.

The powers are high because the currents of up to 10 A are forced to flow through the electrolyte by differences of potentials exceeding 100 V. The law of conservation of energy does not allow the output power to be larger than the input power, unless some exothermic reactions are taking place. Our students often verify that the amount of heat released and the amount of electric energy supplied, to a wire in a calorimeter, are essentially equal. If a student reports that the heat released is larger than the electric energy supplied then I know that some kind of experimental or computational error was made. Such conclusion, however, would not be necessarily valid if chemical reactions were allowed to take place in the material through which electric charges are flowing. For some reactions the excess heat would positive and others it would be negative.

In electrochemical cells used by Naudin excess heat is positive and this indicates that exothermic reactions are dominant. If the excess heat were negative one would know that the dominant reactions are endothermic. But are these reactions chemical or are they nuclear? Unfortunately, the origin of excess power is not discussed by Naudin. By naming his cells "cold fusion reactors" he implies that reactions are nuclear. But this is far from being obvious. After posting Unit #73 (last year) I advertised it on Phys-L, a discussion list of physics teachers. I wrote: "Reasonably reproducible data on abnormal excess heat are described, as summarized in item #73. The French author, Jean-Louis Naudin, calls it a 'replication' of Mizuno's experiment in Japan. I was impressed." Responding to this one teacher wrote: " The cynic sees that the electrolyte is heavy in oxygen and that the plasma reaction produces scum. It would be well to address conventional avenues for the excess heat noted -- say burning a cell component in oxygen....." This teacher thinks that Naudin has no right to say that reactions are nuclear without showing that they are not chemical. As far as I know (by browsing the Internet) the issue of the origin of excess heat in Naudin's experiments has not been addressed. Why is it so? I have no answer.

Let me insert here a brief description for those who might be interested to access information on Naudin's web pages. These pages are highly impressive not only in terms of content but also in terms of its graphical form. But the way of browsing through them might not be obvious. Start with his "summary page" at:

http://jlnlabs.online.fr/cfr/html/cfrdatas.htm

Note that each picture on that page is a link to a more detailed description. Subsequent pages contain similar impressive pictures but these pictures are not links. Some people might not be aware of this. They can also be confused by some underlined phrases. The phrases look like conventional links but clicking on them brings no now information. In other words, the summary page is also a menu leading to fifteen different descriptions. The first of them, containing 11 pages,

is entitled “cold fusion reactor tiny,” the second, containing 8 pages, in entitled “cold fusion reactor v1.4,” etc.

The amount of published data is very extensive. If I were a chemist I would try to replicate Naudin experiments and analyze reaction products. Measuring input power and output power should not be difficult, provided a power supply, and appropriate electrodes, are available. But the issue of calculating chemically released heat, on the basis of the amounts of identified byproducts, would be too difficult to a me. Will I find a chemist willing to participate? This remains to be seen. Showing that Naudin’s excess heat is due to well know chemical reactions would imply that it is not due to nuclear reactions. This would not ruled out a possibility that nuclear processes identified by Mizuno, Ohmori and Oriani, etc., also take place but at rates much smaller than necessary to generate measurable amounts of excess power.

Unlike Naudin, these authors were able to identify nuclear reaction reactions signatures, such as highly unusual isotopic ratios and alpha particles. Let me finish this essay by summarizing the Ohmori and Mizuno paper; it can be found in a special collection of papers from the Infinite Energy magazine at:

http://www.infinite-energy.com/iemagazine/issue20/index.html

Note that only some of these papers are devoted to cold fusion. Eugene Mallove, the late editor of Infinite Energy, supported all sort of unusual claims. Ohmori and Mizuno analyzed a tungsten cathode “electrolyzed at high power.” In that cathode they discovered elements, such as Fe, Cr, Ti, Ca, Ni, C, Re and Pb, that were not present before the high power electrolysis. More significantly, the isotopic ratios for these elements were often very different from the ratios in our natural environment. ^{50}Cr, for example, had the abundance of 6.1%, versus 4.31% found in nature. Likewise, ^{207}Pb, was found to be 55% abundant versus 22% in nature. Production of heavy isotopes indicates that nuclear reactions “are not necessarily conventional deutron-deutron fusion.” Naudin attempt to show that nuclear reactions are present (by detecting gamma rays from the products) was not successful. Nuclear reactions with which we are familiar often produce radioactive gamma-radioactive isotopes while cold fusion products seem to be mostly stable. Obtaining nuclear energy without producing radioactive waste would be highly desirable.

P.S. (10/2/04).
A chemical reaction that should not be ignored is electrolysis of water. It takes 118 kcal (494 kJ) to decompose one mole of water (18 grams). How much water is decomposed in a typical experiment? The energy equation should be written as:

$$Eel = W + Qv + Qc$$

where Eel is electric energy supplied, W is work of decomposition (1.25 eV per molecule), Qv is thermal energy lost through evaporation, and Qc is thermal energy lost through conduction, convection and radiation. Hydrogen is a fuel; why is W not counted as a component excess energy? Also why was Qc ignored? I suppose that Qc is much smaller that Qv when experiments are performed in a thermos. But in an open beaker Qc is certainly much larger. I think that Qc should also be counted as excess heat. In other words, excess energy reported by Naudin is only a lower limit; how large would it be if both W and Qc were added? The main question, after establishing reality of excess heat, is to account for it in terms of products (either chemical or nuclear).

What follows is a set of messages fetched from the discussion group of NFR users:

http://groups.yahoo.com/group/cfr_project

I joined the group expecting to ask questions about the origin of excess energy. But the group appears to be inactive; the last message was posted more than half a year ago.

Date [of message 1 below]: Sat Feb 7, 2004 2:27 pm
Subject: Source of excess energy [in Naudin’s CFR].

Message 1:

Tom, It's already been checked. It's not coming from the tungsten reacting with oxygen or any of the other chemicals present. As I said before, *read the archives*, this work has already been done.

Message 2:
Greetings all,
After many hours of testing and retesting I have come to the conclusion that the excess energy must come from the destruction of the electrode. The byproducts left at the bottom of the solution are artifacts of tungsten that are at a lower energy level. If we figure in the power used in the production/refining of the tungsten electrode there would be a net loss rather than a gain. In effect we have not produced overunity, rather a conversion of matter into energy and a byproduct. As we all know, in any conversion there is some amount of loss in the process. If we come up with an electrode that produces the same effect and remains at the same mass we can claim overunity. Until then it will remain an interesting experiment and no more. I welcome any feedback...

Message 3:
I think you missed the focus or I was not clear enough in my post. I was considering the energy used in creating the tungsten electrode as the part that tips the balance. As you say the chemical portion of the reaction produces a small fraction of the energy released. I don't know how the energy release could be that small. It is my understanding that matter changed to energy takes a bit of power input and releases quite a bit of energy. Has anyone done any work on the artifacts (chemical makeup)? In all fairness any material used up and replaced has to be figured in to get the final, or better, the net power output. On a cost VS production we are creating pennies of extra power for dollars of destroyed materials. Even if the gain was 300% you would not break even on the cost of production. Only if we have a material for the electrode that remains intact, or the cost of energy increases 10 fold or more, will we have gain over the cost of production. What are your COP results for your experiments?

Message 4:
I think your stuck on the chemical reaction. Forget the reaction and concentrate on the cost of materials used verses the extra energy produced. And as for the archives, anyone can post something to the group. Because it gets posted doesn't mean it's true... By the way I didn't see your experimental results in your post. Have you done the experiment yourself? Maybe you just want to debate? I don't have the time to debate pie in the sky. I need real input from real experimenters with real data...Remember, concentrate on the cost of production verses the amount of extra energy not the reaction! Pennies of extra energy for dollars of materials. I can't make it clearer than that without sounding like I'm teaching elementary school children.

Message 5:
The price you have quoted is for tungsten ore. Then you have to process it. A very costly process that uses a lot of energy (consider the melting point of tungsten). Then ingots of raw tungsten are heated again and another purification is done which uses more energy. Then forming machines (using energy) pound the hot tungsten into the shape desired using energy to keep the material hot during the process. Then it has to be shipped and you have to drive your car to the supplier to buy it. Another factor is the chemical for the electrolyte that has to be processed and shipped and so on. And let's not forget your own energy expended to make it all happen. Don't get me wrong, the experiment is quite amazing and we do get more energy out than we put in (from the reaction). But keep in mind that this is only true if electricity alone is consumed and nothing else. As for searching on google, I was not looking for anything so why would I need to do a search? As for attitude, when you have all your ducks in a row, you too can have attitude... (as the they say in a song "Don't try to describe a KISS concert if you have never seen one") My point again: Pennies of extra energy at Dollars of cost is not overunity.

Message 6:
Tungsten costs ~$50 per metric ton.
http://www.google.com/search?hl=en&lr=&ie=UTF-8&oe=UTF-8&as_qdr=all&q=tungsten+price+%24+ton+metric

Considering the relative inexpensiveness of the bulk metal (which is probably in powdered or > granulated form), I expect that bulk purchases of rod, wire, bar or other forms will be considerably cheaper than buying welding rods, which are simply the most convenient form of tungsten available to make a cathode with. The price of said rod is

obviously dictated by market forces, not by the cost of the base metal. However, these matters are immaterial to the science behind plasma electrolysis and are instead of a manufacturing nature. As far as my own experiments are concerned, I am waiting on a step up transformer. When I am done I will have all my reviewed by some off list colleagues before I publish. It appears you want this material spoon-fed. Frankly, I don't have time to hand-hold someone who is so lazy they won't do a basic Google search *and* who on top of it all gives me attitude too boot. Roland,

Message 7:
If you want small quantities, tungsten powder is available for $8 a pound.
http://www.tungsten-heavy-powder.com/Tungsten_Heavy_Powder/Tungsten_Heavy_Powder_Products/tungsten_heavy_powder_products.html

This is the only listed price I've found on the net and is probably quite a bit higher than the market price, given the nature of the source. So I wouldn't be surprised if my initial assessment of bulk tungsten metal being $50 a metric ton as accurate. $50/ton is probably a price for a minimum 100 ton order off a bulk container ship, however...At any rate, if you want large quantities of tungsten stock then good luck on trying to find a price listed on the internet, say for a 10kg billet or 3m of 14mm diameter rod. You can't, because these items are usually sold in industrial quantities and the price probably fluctuates with the market spot price. You probably couldn't even buy those quantities if you wanted to and I expect most companies wouldn't bother with that small an order. This is because small quantities of formed tungsten (billet, bar, rod, wire) are simply not purchased by the general public except in the case of welding rod, there is no end user market for tungsten products except maybe for shotgun pellets for reloading. Tungsten is simply not used for tool stock, etc. as other materials are better suited.

Granted, tungsten is hard to work given the high melting temperature, but that's why it's usually sintered vs. melted & poured into various shapes; so industry has already found a solution to what would be the expensive energy requirements of working the metal. At any rate, the main impediment to the CFR (or any energy device) being put into practical production isn't the cost of materials, it's a dogmatic and entrenched scientific bureaucracy followed by entrenched energy production interests - and their lobbying groups

Message 8:
Thomas, the real cost you need to assess is the recycling cost of the electrodes. Sure the tungsten is expensive first time round, Subsequently, through, it should be cheaper to recycle it rather than dig it out of the ground again.Then again, maybe not, but worth debating.Note that the theoretical chemical energy released is exactly the energy required for recycling the tungsten. Pragmatic inefficiencies will, of course, increase the required energy. However, if recycling energy, including inefficiencies, is less than the energy released in the reactor, then we have net energy gain.

175) Excess heat is not chemical

Ludwik Kowalski (September 14, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Jean-Louis Naudin, whose experiments were described in unit #174, is probably not a chemist. How else can I understand the fact that the origin of excess heat was totally ignored? He does not claim to discover anything new, he simply confirms that excess heat, reported by Mizuno et al., can easily be demonstrated with widely available instruments. This is a very important contribution. If I were in Naudin's position, I would also say that, "according to Japanese scientists, less then 1% of excess heat could be attributed to chemical reactions." Only this context makes "cold fusion reactors" scientifically important.

The paper of Japanese scientists, in which experimental work is discussed in the context of the energy conservation principle, is shown below. Only the text is shown; the entire paper (with two figures and the table) can be downloaded from the library at <www.lent-canr.org>. Will the claim made in this paper withstand the scrutiny of good chemists? I do not know. If it does then the puzzle of excess heat will be taken much more seriously.

Confirmation of heat generation and anomalous element caused by plasma electrolysis in the liquid

Tadahiko MIZUNO, Tadayoshi OHMORI1, Kazuhisa AZUMI, Tadashi AKIMOTO and Akito TAKAHASHI

Abstract

Plasma was formed on the electrode surface in a liquid electrolyte when a metal cathode was polarized in high voltage electrolysis in the solution. During the plasma electrolysis large amounts of heat are sometimes generated. The heat can exceed input substantially, in some cases by up to 200 percent of input power. At the same time, anomalous elements are detected in the electrolyte and on the electrode surface. Based on the heat and the product, we hypothesize a nuclear reaction can be induced by photon activation on the cathode element.

1. Introduction

We previously reported that anomalous isotopes are created on metal surfaces and surface regions, which cannot be explained by ordinary electrolysis.1 In other words, this extruded material consists of elements, which cannot conceivably be contamination, because the isotopic distribution of most of the elements is unnatural. It is thought that this indicates what type of reaction affecting the nucleus has occurred. We expect to clarify the reaction mechanism by analyzing these reaction products. The plasma phenomenon has been in the literature [2-9] for quite a long time. The

reaction mechanism of plasma discharge is not understood in as much detail as ordinary electrochemical reactions.

2. Experimental

Method 2.1 Electrolysis system
Heat was measured by a method that combined open cell isoperibolic calorimetry and flow calorimetry. The cell is a cylindrical glass vessel, 100 mm in diameter and 150 mm tall. A magnetic stirrer to ensure uniform temperature distribution mixes the electrolyte. It has two layers, or chambers. The anode, cathode and electrolyte are placed in the inner chamber. The outer chamber is filled with primary cooling water and heat exchanger coils (Teflon tubing). During electrolysis, secondary-cooling water flows through the coils and removes heat from the primary cooling water. Thermocouples are installed in the heat exchanger coils inlet and outlet, in Tee fittings, to perform flow calorimetry. Cooling water is circulated through the Teflon tubing from a constant temperature bath with an FMI precision metering pump with 1% precision; for example, 4.26Å}0.05 g/s. This pump circulates water at any rate from 1 to 20g/s.
The flow rate is verified by collecting the water in a flask for a fixed period of time and weighing it on a precision scale.

2.2 Heat calibration The heat balance is obtained with the following formulas:

Input (Joules) = I (ampers)*V (volts)*t (seconds)

Output (Joules) = Hw (heat of solution and cell) + Hc (heat of coolant) +
Hr (heat release) + Hv (heat of vapor) + Hg (heat of water decomposition)

All data, including voltage, current, temperature, and mass of secondary cooling water, are collected with a data logger for each 10s. Current is determined by measuring voltage through a shunt. Cell voltage is measured by attaching sensor wires directly to the electrode leads in the top of the cell. Data from the logger is captured by the computer, and finely recorded on diskette. All electric lead junctions from the thermocouples to the logger are compensated.

The heat balance was calibrated by changing the input power of the Joule heater immersing in the electrolyte. The out/input ratio stayed at 0.89 during the calibration run except when the cell was boiling, and during glow discharge boiling seldom occurred. The results show that a large change in input has no effect on the heat recovery calibration. In other words, changes in input power can be precisely monitored by the flow calorimetry method and by the open cell isoperibolic method. The only difficulties arose when the input power is very low, because the temperature precision was only 0.1C, and below 70W measurement accuracy suffered.

2.3 Electrolyte and Cathode Material Preparation
The electrolyte solution was prepared with Milli-Q pure distilled water that is filtered. It was used after being redistill in quartz glass. Ultra high pure reagents were used for the K_2CO_3 electrolyte. High purity of tungsten plate (99.98%) was used for the cathode. Platinum wires or mesh were used as the counter electrode and electrode lead wires.

2.4 Analysis of generated element
Materials in the solution and deposition bottom of the cell were calibrated by ICP analysis. The element on the electrode surface was analyzed by the EDX. The elements were then melted by an acid and calibrated by ICP method.

3. Results
When we increased the input voltage, excess heat was clearly generated. A typical result is shown in Figure 1. With a tungsten electrode of 0.5mm thickness; the graph on the left shows changes of input current, voltage and the electrolyte temperature during electrolysis. The figure on the right shows the input and output in watts and the ratio between them. The output heat showed slight excess comparing with the input power after 2,000s of plasma electrolysis start. After the 3,000s, the excess was considerably larger than the heat measurement error of 20W and reached 30-40W of average during the plasma electrolysis.

Figure 1. Result of small excess heat of 0.5-mm thickness Tungsten plate in 0.2 M K_2CO_3.

Tungsten samples of 0.3-mm thickness also produced significant excess heat generation. A typical result is shown in Figure 2. Excess heat was observed after only 100s of plasma electrolysis. At the time, the excess was considerably larger than the heat measurement error of 20W, reaching 40W average for the first 1,500s of plasma electrolysis. The output and input ratio changed over time. For the first 1,000s, excess was 20%, but after 1,600s it increased to around 60%, with fluctuations. The ratio again increased up to 300% after 3,000s then fell back to one after the voltage decreased to 100V. The total output heat power during plasma electrolysis was estimated as 388.7kJ while the total input electric power of 334.3kJ. Excess heat is 54kJ or 16% of input power.

Figure 2. Result of large excess heat generation during plasma electrolysis of Tungsten electrode.

After the voltage fell to 100V, the output and input ratio seems to fall gradually below unity. The ratio slowly increased after the voltage decreased into 60V. A possible reason is that the electrolysis temperature rose close to boiling point during glow discharge, and heat was lost to the water vapor released from the cell. Although we did not measure heat lost to vapor, the overall balance during glow discharge remained well in excess of unity because so much excess heat was generated. After the voltage was lowered, excess heat stopped although large losses to vapor continued, so ratio fell under unity. At 60 volts, glow discharge stopped, the boiling ceased, and the heat losses to vapor declined, so the balance returned close to unity.

It has been established that at the extraordinary excess heat generation is sensitive to many parameters, such as electrolysis and electrode material. Especially, it depends on the electrolysis temperature, input voltage and the duration of plasma discharge. We observed no excess heat at the beginning of the plasma electrolysis even the temperature and the input voltage were quite high, at 100V and 85ºC. However, after several hundred seconds of plasma electrolysis, we always observed large excess heat generation. We conclude that if we attain sufficiently high temperature and voltage, and hold them, we observe excess heat with 100% reproducibility.

It is apparent that excess energy production depends on electrolysis voltage and the temperature of the electrolyte solution. The discharge voltage at which excess heat production begins is quite different as these conditions vary. Even when these conditions are satisfied, other parameters, such as the shape of the cathode, cause dissimilar discharge conditions. The spectrum of light from the reaction shows that two kinds of reactions can occur. [10] A reaction in which hydrogen dominates in the spectrum, or a reaction in which the alkaline in the electrolyte and the cathode metal, which have no direct role in the reaction, are more pronounced in the spectrum. In the latter case the electrochemical potential near the electrode is large. We assume this affects the excess heat generation.

After excess heat was produced, many elements were found in the electrolyte, the eroded and precipitated cathode material, and on electrode surface. On the other hand, there were fewer elements when no excess heat was measured. Several elements were detected on the cathode surface after excess heat evolution, including Cl, Ca, Ti, Fe and Zn. The distribution of the elements was different in different parts of the electrode surface. Most were found around the center of sample. Meanwhile, other elements were detected in the solution, which were not the same as those found on electrode surface and the deposition at the bottom of the cell. Typical element distributions are shown in the Table 1. A clear difference can be seen between the case when excess heat was generated, and when it was not.

4. Discussion

In evaluating heat production, is necessary to consider whether the heat might have been produced by chemical changes. After discharge electrolysis it is clear that the cathode material was worn down and precipitated to the bottom of the cell in the form of fine particles. Because this material was entirely made up of pure metal, the destruction must have been caused by hydrogen corrosion as well as heat damage. Therefore chemical changes cannot explain the heat. Ignoring the fact that this is impossible, let us consider some hypothetical chemical reactions:

$2W+3O_2=2WO_3 + 200.84kJ$
$WO_3+H_2O=H_2WO_4 + 179kJ$

In other words, if 183.85g of tungsten reacted, the maximum heat generation from this reaction would be 380kJ. The

actual volume of excess heat measured using flow calorimetry was 54.4kJ for the case of plasma electrolysis with 200V of input for 3.1ks. The mass of tungsten removed in the reactions described above was 0.1g, and if we assume hypothetically that all of this material reacted, the heat would have been only 0.207kJ or 0.38% of the actual excess heat observed. The heat production in this experiment cannot begin to be explained as a chemical reaction.

This discussion has been predicated on the supposition that the tungsten underwent a chemical reaction, but in reality the tungsten found at the bottom of the cell was recovered as pure metallic fine powder, so no chemical reaction occurred. Furthermore, the decomposition of carbonates in a water solution is an endothermic reaction, so in this case 274kJ/M of heat would be absorbed, therefore even assuming that a reaction occurred no excess heat would be produced. Ordinarily, when metal is transformed into a hydride, it produces on the order of 200kJ/M, the exact amount depending on the metal. If a hydride was formed, based on the amount of tungsten lost from the cathode, the excess heat from the reaction should have been 0.1kJ approximately, which is simply too small to make a difference. In short, the actual heat that might have been produced from potential chemical reactions is essentially nonexistent.

5. Conclusions

According to many reported experiments, in almost all cases no radioisotopes have been detected, and no radiation or only very weak radiation such as neutron and other gamma or x-rays have been detected during and after the cold fusion experiment. We have to explain the fact by a plausible mechanism that produces no radioactive materials and might be trigged by the the electrochemical reactions. Takahashi [11] has made progress the mechanism of photo-fission for the case of palladium, the material usually used in cold fusion experiments. We understand that the Takahashi hypothesis also applies to a tungsten electrode.

Table 1

There are two peaks for the element distribution of the product of Tungsten electrode as shown in Table 1. One peak is the major element of iron and zinc and other is the In. The total generated amount of element for the case of excess heat evolved was calibrated as the order of a milligram. Meanwhile, the total excess heat was calculated as on the order of 10^6J from the products. The mechanism is well explained the excess heat evolution. We can say the photo-fission mechanism explain the amount of excess heat and the distribution of the element generation during the electrochemical treatment.

176) Very convincing results

Ludwik Kowalski (September 19, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Two days ago I received an e-mail message from a cold fusion researcher, Dr. Richard Oriani. It was prompted by my letter to the editor of Physics Today.

"I read your recent letter to Physics Today with interest. I hope that the DOE panel will answer questions to your satisfaction. I presume that you know that I for one am certain that the phenomenon that is poorly labeled as cold fusion is real. I would like to send you two papers for your consideration, having to do with alpha particle generation. I need your full address for that mailing. I remain highly frustrated by irreproducibility despite having tried hard. I regard the solution of this problem as very important for acceptance of cold fusion by the nuclear community. I suspect that progress in developing reproducibility depends on developing understanding of the basic physics, and this in turn depends on developing reproducibility so that control of the relevant parameters will be possible. A chicken and egg dilemma !"

As described in unit #108, I met Richard Oriani at the last cold fusion conference; he is a retired teacher (like I am now) in Minnesota. Oriani probably forgot my name and is not aware that I am the same person who corresponded with him about a year ago. Are the papers he is sending me now new or are they the same as those presented at the last cold fusion conference? I will know in a day or two. Meanwhile I reread his last year papers and decided to summarize one of them. It describes an experiment that seems to be suitable for student projects. The papers shows that unexpected charged particles are emitted in a very simple electrochemical cell. The idea of using ordinary water and a nickel cathode (instead of less accessible heavy water and palladium) is very attractive.

The experimental setup is essentially a test tube containing a solution of Li_2SO_4 in water (concentration 25 grams/liter) and two electrodes: Pt (anode) and Ni (cathode). An electric current, such as 0.2 A, flows through the cell for several days. An identical setup is used in a control experiment; the current in that experiment is zero. Energetic nuclear projectiles, most likely protons or alpha particles, were recorded with CR-39 detectors immersed in the solution. The number of observed particles in the control tube were found to be significantly lower than in the tube through which the electric current was flowing.

Unfortunately results are not reproducible; track densities fluctuate widely from one observation to another. But the average track densities from control cell were much lower that form the cell in which the electrolysis was taking place, as illustrated below. The cause of fluctuation remains unknown and the author is "highly frustrated by irreproducibility despite having tried hard." Recognizing "hidden variables" in cold fusion experiments is the number one task for those who conduct research in that area of science. Let me mention that electrostatic experiments were also highly irreproducible before air humidity was recognized as a hidden variable. The same was true for semiconducting devices, before the importance of extreme cleanness was recognized.

The first column below shows the outcomes from 32 measurements made in the cell with the current while the second column shows the outcomes from 16 measurements made in the cell without the current. The sorted numbers represent tracks per square centimeter (and per equal time of one run, I suppose). How can there be any doubt that the first set of data is very different from the second? The average from the first column is 469.7 while the average from the second is 165.2. The corresponding median values are 328.5 and 136.0, respectively. This indicates that the distributions are not

Guassian.

With current	Without current
1405	64
1355	338
1202	272
993	260
982	260
922	160
898	143
741	142
532	130
532	130
510	107
402	95
390	95
390	83
335	78

A skeptic might suspect that excess tracks observed in CR-39 detectors are not due to swift nuclear particles but to something else, such as bubbling, associated with the current. This possibility was investigated by Oriani; detectors subjected to intensive non-electrolytic bubbling did not reveal more tracks than detectors used in the control cell. Experimental data in which heavy water and palladium were used produced equally significant results, as described in papers of Oriani at al. These papers can be downloaded from the library at <http://www.lenr-canr.org>.

178) Recent messages and comments

Ludwik Kowalski (September 21, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

I often receive cold-fusion-related messages. Let me share some of them here.

1) On September 18, 2004 a stranger wrote: “I refer to your Physics Today letter concerning ‘Seeking Answers From Cold Fusion Review.’ The Golden Rule of science that I was taught was: Reproducibility. If a phenomenon can't be reproduced, it cannot be measured, it cannot be counted and is therefore inaccessible to analysis by mathematics. If a phenomenon can't be corroborated it will not be accepted by a consensus of scientists working in the field.

2) My immediate reply was: “I agree with you. Cold fusion is not an established scientific discipline. Neither was electrostatics at the time of B. Franklin. The main hidden variable at that time was humidity. That is why experiments were highly irreproducible. Do you think that cold fusion findings reported by qualified scientists (in the last five or ten years) are based on fraud? Do you think that methods of validation used by them are different from those used in other areas of physics and chemistry? Do you think that they are ignorant charlatans or highly skilled con artists?

Who are you and why are interested in cold fusion? I am a recently retired physics teacher trying to find a way to check some claims made in the area of cold fusion. I will not hesitate to say that my data contradict the reported claims, if that is going to happen. The null hypothesis is going to be that claims are not valid (because they are so extraordinary). I hope to hear from you again.” Today is September 21; I do not know why that person decided not to answer. But that is OK with me.

3) I asked a friend in France about the attitude of French scientists toward cold fusion. Replying to my message (on September 20) he wrote: “People here are quite reluctant - as I already told you - concerning cold fusion. At the beginning there had been much excitement, but at that time all serious experiments which were performed showed that the effects observed were due to background. I just have seen, and read, your letter to Physics Today (it arrives much later on this side of the Ocean); it is quite all right... “

During my trip to France, to participate at the 11th International Conference on Cold Fusion (see http://www.iccf11.org>), I will ask what my friends know about recent cold fusion claims. I suspect that many of them think that cold fusion is pseudoscience, not worth their time. In other words, the situation there seems not to be different from that in the US. The word “reluctant” is interesting. Does it mean they are ready to change their minds when (and if ?) convincing experimental evidence is presented in peer reviewed papers? I hope so. Most scientist are open-minded.

4) Several days ago I discussed a cold fusion topic with someone over the Internet. After answering my questions (on September 17) that person added: “I suspect that many would be reluctant to become involved in CF because of its stigma as fringe science. This stigma may or may not be deserved. The point of any experiment is to answer a question, and in my personal but far from universal opinion there is something to be learned by further research into electrochemical CF. So, do you have any suggestions? What has been your experience with colleagues?” I said that I understand the fears of being negatively labeled. Then I resumed our discussion about instruments to be used.

Responding yesterday (September 20) he wrote: “I received your message. Sorry about the delayed response; I had to give this some consideration over the weekend. I believe that there are a few minor misunderstandings in what you say that you learned from me, and I'll address these in another email if you wish. If you want to include our URL in your

item, that is OK, but I would prefer that you not use my name. This is just to put a little public distance between me and CF experiments..... " Hmm, a person willing to discuss nuances of an anticipated CF experiment in private is reluctant to associate his name with that topic publicly. I know that he is an open-minded individual. But he is also realistic; he knows what others think about cold fusion and he does not want to be responsible if his institution is labeled as pseudoscientific.

5) On September 20 a stranger wrote: "Hi, I've been following your site with interest for a few months. Bob Park is bothered by the anonymity of the new DOE panel reviewing cold fusion. (see below). The first DOE panel on cold fusion was not anonymous. However, anonymous peer review is the norm for many prestigious journals. Maybe if the first panel had remained anonymous cold fusion studies would not have been so stigmatized." He then pasted what Bob Park wrote (on September 17 at <http://www.aps.org/WN/>) about the DOE investigation. Here is that piece:

"COLD FUSION: DOE REVIEW IS HIDDEN BEHIND A CLOAK OF SECRECY. Believers see DOE's review as vindication after 15 rough years (What's New, 2 Apr 04). But watchers are puzzled by how little is known about the process. Who are the reviewers? Who are they talking to? What's New hears that DOE is claiming anonymous peer review. That shouldn't please anyone. The controversy will simply continue. Bob Park can be reached via email at whatsnew@bobpark.org THE UNIVERSITY OF MARYLAND. Opinions are the author's and are not necessarily shared by the University, but they should be."

6) This interesting message shows that information about the panel composition (which was shared with me by X) is not widely known. I do know when the deliberation took place and who was present. This is likely to become public knowledge very soon. I already commented on what Robert Park wrote about cold fusion in his book "Voodoo Science." It's a good book but I disagree with Park's idea of placing cold fusion researchers in the same category as astrologists, UFO-logists and con artists. One should not be surprised to discover con artists pretending to be scientists; there so much to gain and so little to lose. Bob, and his Russian counterpart, Krugliakov, did expose many pseudoscientific swindlers. And they deserve credit for this.

But Bob's position on cold fusion is wrong. Why do I think so? Because I have not seen anything scientifically-convincing in his accusations. He seems to be sticking to old arguments and ignores new claims (in his book and in What's New internet messages). My impression is that he is totally unfamiliar with recent cold fusion publications. I did not see him at the cold fusion conference last year. He was personally invited by the co-chair, I heard, but decided not to come. That is strange; the conference would offer him an opportunity to learn about new findings, and to engage scientists whom he ridiculed in numerous public addresses. He always presents himself as a scientist. So why was he not willing to discuss cold fusion topics with other scientists? I can understand my fiend in France, he is active in other areas and has no time to read cold fussion litarature. But a material scientist who publicly treats cold fusion researchers as if they were charlatanes has a moral obligation to be seriousely involved. Will Dr. Park come to the conference in Marseilles? I would welcome an opportunity to speak with him, and to write about our conversations. I wish I had his writing skills.

7) A person I met at the cold fusion conference last year wrote to me (on September 15) about a book he is writing. In a reply I said that I would be interested in seeing one or two chapters. The entire draft was sent to me as an attached file. I read parts of it and made some comments. The message ended with the "I wish you luck in publishing the book." The reply surprised me; the author wrote: "I am not going to try to publish it. When it is finished and it has been reviewed by several researchers and friends, I will upload it to .....[web site was given] along with our other papers. I will not copyright it. There is no point. No publisher will touch a book about cold fusion, and people will not pay money to read about it. This goes back to Howard Aiken's dictum: 'Don't worry about people stealing your ideas. If your ideas are any good, you'll have to ram them down people's throats.' " I have no doubt that good books about cold fusion will be in demand, no matter what the final verdict of DOE will be. Cold fusion is not only science; it is also an interesting social phenomenon. The phenomenon might be indicative of something very profoud on the subject of "science and society."

8) I am appending an important paragraph at the bottom of item #177; it has to do with an attempt to find someone willing to donate a set of proceedings from cold fusion conferences to an accessible library. Please contact me about this:

180) Preserving Cold Fusion Documents

Ludwik Kowalski (October 1, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

About two weeks ago I wrote a letter to Dr. R. J. Anderson, the Director of the Niels Bohr Library. That library, located in Maryland (near the capital of USA), is the Center of History of Physics of the American Institute of Physics. This item shows two original snail-mail messages and subsequent e-mail messages. My appeal to those of you who might be willing to contribute is shown at the end. Preserving cold fusion documents in a central location, particularly in the prestigious Niels Bohr Library, is worth supporting.

= =

Dear Dr. Anderson:

I am a recently retired physics teacher interested in cold fusion. You are probably aware that the CF field is very controversial (see my letter to the editor in the last issue of Physics Today, September, 2004). I would like to know what CF materials are available in the Niels Bohr Library. More specifically, I am interested in proceedings from International Cold Fusion Conferences listed below. They are not available in most research libraries, probably because this field is not recognized as scientific. I hope that the Niels Bohr library has the proceedings because they reflect evolution of a unique scientific controversy. If not then I would appreciate information about a library, or institution, that collects and preserves such items.

Proc. ICCF1 (1990):
Proceedings of the First International Conference on Cold Fusion, (ICCF)
Mar. 1990 Salt Lake City, UT, edited by F.Will.

Proc. ICCF2 (1991):
The Science of Cold Fusion, Proc. of the Second Annual Conference on Cold Fusion, Como, Italy, June 29-July 4, 1991, edited by T. Bressani, E. Del Giudice and G. Preparata, Published by Societa Italiana di Fisica, **33**.

Proc. ICCF3 (1993):
Frontiers of Cold Fusion, Proceedings of the Third International Conference on Cold Fusion, Oct. 1992 Nagoya, Japan, edited by H. Ikegami, Universal Academy Press, Tokyo.

Proc. ICCF4 (1993):
Proceedings of the Fourth International Conference on Cold Fusion, Dec. 1993 Maui, Hawaii, edited by T. O. Passell and M. C. H. McKubre.

Proc. ICCF5 (1995):
Proceedings of the Fifth International Conference on Cold Fusion, Monte Carlo, Monaco April 9-13, 1995, IMRA Europe, Sophia Antipolis Cedex, France (1995).

Proc. ICCF6 (1996):
Proceedings of the Sixth International Conference on Cold Fusion, October 1996

Hokkaido, Japan, edited by M. Okamoto.

Proc. ICCF7 (1998):
Proceedings of The Seventh International Conference on Cold Fusion,
Vancouver, Canada, April 19-24, 1998, ENECO, Inc., Salt Lake City, UT (1998).
Proc. ICCF8 (2000):
Proceedings of the Eighth International Conference on Cold Fusion, May 2000
Lerici (La Spezia), Italy, edited by F. Scaramuzzi.

Proc. ICCF9 (2002):
Proceedings of the Ninth International Conference on Cold Fusion, May 2002
Beijing, China, edited by X. Z. Li.

Proc. ICCF10 (2003):
Proceedings of the Tenth International Conference on Cold Fusion,
August 2003 Cambridge, MA, edited by P. L. Hagelstein and S. R. Chubb,
World Scientific, to appear.

CF will be part of the history of physics, no matter what conclusions are reached about the validity of its claims. Leading researchers in that field, such as Steven Jones, Martin Fleischmann, Mike McKubre, and John Bockris are recognized authorities in their disciplines.

Unable to locate the above proceedings in local university libraries, and suspecting that nobody gathers them, I would like to suggest that your library take the initiative to collect and preserve CF documents for the benefit of future generations. Scientists who attended earlier conferences might be willing to give their own copies to the library. They might even be willing to be interviewed by a historian of science.

My own involvement is recent; the only conference I attended was ICCF10, last year. But I want to become a cold fusion researcher. That is why I am going to attend the next conference in France (see http://www.iccf11.org). With your approval, I would be willing to make an appeal urging old-timers to donate their copies of procedures to the library. Please note that such a conference is an ideal place for a historian of science to interview old-timers. Most of them are eager to talk about personal experiences in the CF field. Opportunities for interviewing some of them might not be available in a year or two.

If the library already has cold fusion materials then I would very much like to examine them after the conference. Please let me know if this is possible. Other researchers might become interested in the CF proceedings after the report from the ongoing DOE investigation is published. Attached is my modest donation to help support the library. Respectfully yours, . . .

= =

Dear Dr. Kowalski:

Thank you for your recent letter regarding cold fusion materials and for kind donation to the Friends of the Center for History of Physics. We appreciate both the contribution and the offer to help us obtain copies of the proceedings of the international conferences on cold fusion.

We do not have the proceedings and would be pleased to have you ask participants at the upcoming conference in France for copies on our behalf. We've checked online to determine if any one library has the proceedings for all ten conferences, and we weren't able to locate any that do. However, many university libraries have proceedings for one or a few of the conferences, and the University of Michigan catalog shows holdings for all but the first. For your research, you should be able to ask your local university or public library to obtain them for you through interlibrary loan.

I appreciate your suggestion that we conduct oral history interviews with cold fusion researchers. Unfortunately, however, the Center has limited resources to devote to oral history and a very long list of scientists to interview,

including even some Nobel laureates who have not been interviewed by historians. However, we do offer grants in aid (http://www.aip.orc/history!web-arnt.htm) to historians of science who are interested in conducting interviews with scientists in their own areas of interest, and we can sometimes also offer free transcription for interviews in physics and all of its fields. In addition, the Cornell University Cold Fusion Archives has conducted some interviews.

We do have here videotape recordings of the Special Session on Cold Fusion that was sponsored by the American Physical Society in 1989. Another collection that may be of interest is the Steven Jones Papers at the Marriott Library, University of Utah. I've enclosed a catalog description of the Special Session on Cold Fusion videocassettes, along with descriptions of the Cornell University Cold Fusion Archives and the Steven Jones Papers. I've also enclosed a copy of our Application for Access form. If you would like to use the Special Session videocassettes, please complete the form and send it to us. . . .

= =

Prompted by the above I started thinking about another initiative; it is summarized in this e-mail message:

Dear Dr. Anderson:

Thanks for the reply. I will make an appeal and hopefully somebody will donate the entire collection to the library. I will let you know. In the letter you say that only financial limitations prevent you from sending a historian to interview one of the cold fusion scientists that I mentioned. I have a question about this. Suppose that during the conference (which I am going to attend) I find a person committed to the cause (preserving cold fusion history) and willing to donate a sum of money. Would you accept a donation which is dedicated to a particular field (but you choose the scientist)? If this is acceptable then I will start asking. Can you please indicate, based on experience, how much it costs, typically? And one more question. Is it OK if the letter I received today is shown to others. They are likely to react positively to my appeal by reading what you wrote. Sincerely yours, . . .

= =

Here is the reply form Spencer R. Weart, the Center's director:

Dear Dr. Kowalski, We hope your appeal succeeds; the conference proceedings would be a fine addition to the collections of our Niels Bohr Library. Certainly you can show Joe Anderson's letter, and this or any of our other e-mails, to anyone.

We are glad to help support interviews with physicists whenever an appropriate interviewer can be found. In our grants-in-aid program, we will support any qualified historian (someone with publications in history of science, or enrolled for a degree in the field) and let them choose who is to be interviewed. The first problem is thus to find the historian. I don't know any who have been studying cold fusion -- certainly it is a fascinating topic but there are so many other topics to study, and historians usually look at things farther in the past. Thus it would be necessary to advertise in the history of science community and see if we could find, for example, an underemployed postdoc who would like to do it as a job.

Oral history interviewing is surprisingly expensive. For an ongoing program in oral history, there is an incremental cost of about $750 per hour of interview to do the research, make travel arrangements, conduct the interview, and transcribe, edit, and catalog the tape-recording and transcript. Thus a typical three-hour interview would have an incremental cost of $2250. But for a new project there would also be start-up costs (hiring the interviewer and other administrative arrangements, initial research to select the best interview subjects, etc.). A minimum of $15,000 would be needed to initiate a program that would conduct in-depth interviews with several pioneers, perhaps totaling ten interview hours or a bit more. The selection of people to be interviewed would be up to the historian, but of course your advice, and the

advice of others in the community, would be seriously considered. All that said, I can't guarantee we could find a suitable interviewer, but the chances are pretty good.

An alternative would be for you to find someone, not necessarily a trained historian, interested in researching and conducting the interviews as an unpaid volunteer. We could then offer guidance in how to go about it, and could probably provide some travel funding through a grant-in-aid, plus a limited amount of transcription and cataloging. If more than a few interview hours are done we'd need a bit of support for the transcription and cataloging. The problem of course is to find someone who is interested, which would probably be someone in your community, and who would at the same time interview in a thoroughly objective fashion. Sincerely, Spencer Weart

= =

This item (#180) will be “advertised” on two discussion lists: Phys-L, and Newsletter. The first list is read by many science teachers; they may help to find a historian. such a person should contact me. The second list is read by members of iscmns (International Society of Condense Matter Nuclear Science); I will suggest to them how the collection of conference proceedings might be organized.

Needless to say, I am composing this item for a broader group of potential readers. Contact me if you, or somebody you know, are interested in helping the project. Keep in mind that cold fusion will certainly be considered an important episode in the history of science, no matter what the final verdict about its claims will be. My e-mail address is:

<kowalskil@mail.montclair.edu>.

181) A new book about cold fusion

Ludwik Kowalski (October 8, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Last night I received an advance copy of a just-published book about cold fusion by Steven Krivit. The title of the book is "*The Rebirth of Cold Fusion;"* the second author is Nadine Winocur. My first intention was to browse through the book and then share my first impressions. But I changed my mind, after seeing how the book is introduced by several people. It is better if I show what they wrote in the opening pages:

Advance acclaim for
The Rebirth Of Cold Fusion: Real Science, Real Hope, Real Energy
Steven B. Krivit and Nadine Winocur, Psy.D.
Foreword by Sir Arthur C. Clarke
http://www.newenergytimes.com

1) "*The Rebirth of Cold Fusion* is a very important and timely book. It may help educate a generation of physicists told to believe cold fusion doesn't exist. I look forward to future editions describing a definitive theory of the phenomenon."
- **Robert H. Parmenter**, Emeritus Professor of Physics, University of Arizona, and co-author of "Cold Fusion in Metals" (Proceedings, National Academy of Science, Vol. 86, 1989) with Willis E. Lamb, Nobel prize winner in Physics, 1955

2) "Basic research and its progress depend upon how open the society is to accept new ideas and pursue them to the end - right or wrong. *The Rebirth of Cold Fusion* brings out the important question of whether the present form of peer review and financial control by government agencies help in new innovations or not. It is obvious that some changes have to be made, with the future in view."
- Dr. P. K. Iyengar, Chairman (retired), Atomic Energy Commission, India

3) "The Rebirth of Cold Fusion is an important report in the good tradition of American investigative journalism. It exposes a scandalous case of scientific misconduct, engages those who are guilty of foul play, and sets the record straight. The book comes at a critical moment in which a neglected field of inquiry is fighting for recognition. Let's hope it helps cold fusion gain the support a potential energy source deserves. Everybody should be aware of the facts in this book.
- **Haiko Lietz,** Science Reporter, Germany

4) About Cold Fusion
"The only thing pathological about cold fusion is the way the scientific establishment has treated it." -
Sharon Begley, "Cold Fusion Isn't Dead, It's Just Withering From Scientific Neglect" (Wall Street Journal), Sep. 5, 2003

5) "No cover-up like this has happened before. It is a profound scandal in American science."
- **Charles Beaudette**, author, *Excess Heat & Why Cold Fusion Research Prevailed*, 2002

6) "In regard to cold fusion, it would be advisable for the scientific community to brace itself for the fallout that will be coming soon when the public starts to become aware that the scientific community was engaging in an act of gross self-deception back in 1989."
- Brian Josephson, Nobel prize for physics, 1973

7) "Cold fusion may provide a clean nuclear energy to mankind. Since I have worked long in nuclear engineering, it is a dream of nuclear energy."
- Akito Takahashi, professor, department of nuclear engineering, graduate school of engineering, Osaka University

8) "If Professor X.Z. Li [Tsinghua University, China] is correct, then I'll have to throw away about 14 of the 16 chapters in my book *Introduction to Fusion Energy*, because it will no longer be relevant to the kinds of fusion that could result from this 'cold fusion' process."
- Dr. J. Reece Roth, head of the industrial plasma engineering group, University of Tennessee

I am still open-minded about cold fusion claims. At present I am more interested in papers of research scientists than in books focusing on social and historical aspects of cold fusion phenomenon. That is why I will wait a while before reading this new book. Let me mention another item, a paper, not a book, that is worth reading. It is available over the Internet at:

http://www.newenergytimes.com/library/2004JosephsonB-LindauLecture.pdf

The author, Brian Josephson, is a Nobel Prize Laureate. He is a physicist but this paper is a set of philosophical reflections. Josephson writes about validation of scientific claims, and about social aspect of cold fusion. Note that he is one of those who was quoted above.

Josephson's paper can also be downloaded from the library at www.lenr.canr.org

http://lenr-canr.org/acrobat/JosephsonBpathologic.pdf

The most important cold fusion papers (organized alphabetically by the first author) can be found in that library. Its downloadable pdf files are usually not available anywhere else. The library is a widely used resouce for cold fusion researchers.

182) With my own eyes...

Ludwik Kowalski (October 13, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Yesterday was a highly exciting day for me. I discovered a lot of tracks of charged particles on CR-39 detectors applied to a cathode provided by Dennis Letts. How can I describe that "day of glory"? One way is to show relevant e-mail messages, some old and some recent. Let me begin by mentioning that item #169 was based on work by Dennis Cravens and Dennis Letts. My detailed results and pictures will be presented in unit #183.

8/21/2004 (from L.K. -->Dennis Letts)
Dear Dennis and Dennis: I read your "Appeal to Researchers" and I would like to be involved. I am Ludwik Kowalski, a physics teacher at Montclair State University in New Jersey. I am interested in cold fusion. ..... What I would like to do, as soon as possible (preferably before traveling to ICCF11), would be to examine your Pd with CR-39 detectors. I have everything needed. Your ICCF10 paper gives no evidence that the excess heat has nuclear origin; observing tracks due to alpha particles and protons (above natural background) would provide the needed evidence. P.S. I have a Ph.D. in nuclear physics (1964) and I have worked with many different detectors of nuclear particles. But this was long ago. Experience with CR-39 is very recent.

8/27/2004 (from Dennis Letts --> L.K.)
Ludwik, We have just started a new series of tests; our first cathode in this series, #613, produced a large amount of apparent excess power during the loading phase at low current: .05 amps, 3.3 volts. Dennis and I will send you this cathode and any subsequent cathodes that appear to produce excess power for analysis.

We do require that the cathodes be returned after analysis; further, we do not plan to release any experimental details until after all of the experiments are completed, projected to be by December 31st, 2004. Of course, you are free to release/publish your findings whenever you wish. We assume that you will give us a copy of your findings when they are complete. Please send your mailing address if this arrangement is acceptable. Dennis Letts, Dennis Cravens

8/27/2004 (from L.K. -->Dennis Letts)
Hi Dennis and Dennis: I will be very happy to examine your cathode. I will place the CR-39 on top of it for about two weeks. Then I will send the sample back to you. I will release nothing without your OK. . . .

8/27/2004 (from D.L. --> L.K.)
[You wrote.....] This series of experiments is closed at the request of those with whom we are collaborating. [You wrote . . .] We are not developing anything new at the moment--only demonstrating what we have already published and the community is welcome to all of that information. [You wrote.....] Unfortunately we are in "demo" mode now and will be in this mode until December 31st, 2004. My phone number in Austin, Texas is ..... [You wrote.....] I will send cathode #613 Monday; cathode #615 will begin testing Saturday evening. If it makes excess power I will send it as soon as it comes out of the cell.

8/28/2004 (from L.K. --> D.L.)
I will be ready for your samples #613. And good luck with the sample #615. As I said, you will be informed about all that I do on your cathodes. Thanks for sending them. At what average rate was the excess heat generated in the sample #613, and for how long?

8/28/2004 (from D.L. --> L.K.)

Ludwik, I had hoped that I made our policy clear on my first e-mail: No experimental details will be released until the series of experiments is complete, projected to be December 31st, 2004. This is NOT our normal policy but our current situation requires that we work in this way. The only fact you will know before December 31st, 2004 is that the cathode made apparent excess power. If this arrangement is satisfactory for your purposes, please confirm in your next e-mail.

8/28/2004 (from L.K. --> D.L.)
Dennis: Yes, this arrangement is satisfactory. I know that you have the information and that it will become available later. I will assume that your policy has something to do with the patent aspects of the project. If I see a lot of tracks due to charged particles (well above the background) then we will address the issue of when and how to share this component of YOUR work with others. I am doing a trivial thing while you discovered something innovating and challenging. Thanks again for the offer. . . .

8/28/2004 (from D.L. --> L.K.)
The policy of "no information until we're done" has nothing to do with patent issues--all of our information has already been made public. It has ONLY to do with not wanting to release incomplete information to the community. This series of tests will be a confirmation/demonstration of the laser effect or a repudiation of the laser effect. We want to make sure ALL of the results are known before we go public with the data.

8/28/2004 (from L.K. --> D.L.)
1) That is a very good policy; Fleischmann and Pons paid a heavy price for not following it. 2) As you know, I have a web site on which I summarize what I learn and think about cold fusion. I am reading your ICCF10 paper and I want to have an item based on. The first draft is about 50% finished. The attached file (in the MS Word format) shows what I wrote so far. I will send you the finished draft later, and will ask for corrections, if necessary. I will stop writing (and will not post my essay) if you have an objection. Let me know.

8/28/2004 (from D.L. --> L.K.)
. . . Neither Cravens nor I want to have any editorial control over your work--write and publish as you wish. We only ask you to use the usual care when attributing a quote to us..... Cravens and I say very little publicly outside of our contributed papers or slide presentations. Everything we currently know about laser stimulation is on the LENR-CANR web site in the form of our papers and slide presentations..... Please continue your work as you see fit.

9/1/2004 (from L.K. --> D.L.)
Hi Dennis: When should I expect to receive the sample (or samples)? Ludwik

9/1/2004 (from D.L. --> L.K.)
. . . I will send cathode #613 Monday; cathode #615 will begin testing Saturday evening. If it makes excess power I will send it as soon as it comes out of the cell. [You asked:] **"**Did you find a lot of excess heat from the last cathode?" **Yes, it appeared to do so.**

9/2/2004 (from L.K. --> D.L.)
1) Thanks sharing good news about your work in progress. I am ready for the cathode. 2) The CR-39 detector is thick enough to stop the charged particles (such as 3 MeV protons observed by Jones or alpha particles). Therefore the side of CR-39 in contact with the cathode will be use to get the "signal + background" while the other side will be for the "background" only (from radon, etc.) I should have no trouble with the identification of the signal if one side has more than ten times more tracks than the other. We will see.

9/7/2004 (from L.K. --> D.L.)
The cathode just arrived. I at once sandwiched it between two pieces of CR-39. The third piece will later be exposed to an alpha source for 10 seconds. All three pieces will be etched at the same time. I would like to keep the exposure (of your cathode to CR-39) for several weeks; the longer the better. Is anybody waiting for this cathode? Let me know. Thanks for allowing me to participate.

9/8/2004 (from D.L. --> L.K.)
There are no other tests planned for the cathode, keep it as long as necessary.

9/16/2004 (from L.K. --> D.L.)
The ICCF11 abstracts must be submitted before 9/30/04. I would like to make a short presentation based on my analysis of tracks from two foils: your Pd and Jones' TiDx foil that I processed in June. . . . My abstract is shown below. . . .

9/20/2004 (from D.L. --> L.K.)
That's fine with me--I'll be very surprised if there is any evidence of nuclear activity but all efforts are worthy and should be pursued. Good luck!

9/20/2004 (from L.K. --> D.L.)
Your second sample arrived and I just sandwiched it between two pieces of CR-39.

10/1/2004 (from L.K. --> D.L.)
Your third cathode arrived today (10/1/04) and has just been sandwiched between two CR-39 detectors. I will etch all detectors in about two weeks.

= = = = = = = And here are messages from yesterday and today = = = = = = =

10/12/2004 (from L.K. --> D.L.)
Last evening I opened all three CR-39 sandwiches (exposed to your three cathodes) and etched them.

Cathode A (sent to me on September 7) after 820 hours of exposure (your #613 ?)
Cathode B (sent to me on September 21) after 485 hours of exposure (your #616 ?)
Cathode C (sent to me on October 1) after 266 hours of exposure (your #615 ?)

The first quick inspection showed that:

1) Practically nothing from cathode C
2) Some tracks from cathode B (perhaps 10 or 20 times the background)
3) A huge number of tracks from cathode A (perhaps 1000 times the background)

I just placed fresh CR-39 detectors on cathodes A and B to see if they are still emitting charged particles. We will know in several weeks (after my return from the ICCF11 on November 10).

Here are some preliminary observations concerning cathode A:

Both sides were emitting particles but one side has about ten times more particles per unit area than the other. By looking at the cathode I see that one side still shows the trace of the wire that was supporting it. That side shows fewer tracks that the other side. The side that has more tracks shows clustering; I can identify at least two fields of very high track density. All tracks are quite different from those due to alphas from my Am-241 source; it may be that they are not due to alpha particles.

It is your experiment, Dennis, and you should decide what to do with this information. You wrote that you plan to release all findings at the end of the year. It would be difficult for me to keep quiet at the ICCF11; my talk is based on tracks I observed from a TiDx foil that Steven Jones sent me last spring. But I will keep quiet, if you prefer. I would very much prefer to rewrite my ICCF11 paper (with you as the first author) to include new results. Even your cathode B has many more tracks than Steven's TiDx foil. My intention was to talk about difficulties (and possible bias) in counting rare tracks. But how can I talk about this now? . . .

Naturally, your input is essential. You do not have to reveal everything in the ICCF11 paper; just provide some minimum and refer to pending publications. While awaiting your reply I will select some pictures of what I saw today under the microscope. I will send them to you as an attached file. Let me know what you think. You can call me, if you prefer.

10/12/2004 (from L.K. --> D.L.)
I SUSPECT THAT THIS FILE WAS NOT SENT PROPERLY ABOUT AN HOUR AGO. IT DESCRIBES THE FILES THAT WERE ATTACHED TO MY LAST MESSAGE.

1) file 00... Magnification 40. The distance between small divisions is 0.01 mm
2) file 14... alpha particles from Am-241 (magnification 40)
3) file 15... alpha particles from Am-241 (magnification 200)
4) file 27... cluster of tracks from the cathode A (magnification 40)
5) file 29... outside the cluster (same side of the same cathode (magnification 40)
6) file 32... same tracks under magnification 200

It looks like your particles are much more penetrating than alphas of several MeV. They are able to traverse my detector. But I must take another look to be sure; the microscope is at school and I am at home now.

10/12/2004 (from D.L. --> L.K.)
Ludwik, Dennis Cravens and I are pleased to hear about your positive result and encourage you to report your result at ICCF11 in any manner you choose. We decline your kind invitation to be co-authors because this is your work and it should remain independent of us. A minor acknowledgment for Letts, Cravens and Earthtech International would be more than sufficient.

We will provide experimental details concerning the 3 cathodes you have analyzed in order for you to write a meaningful paper. Let me know what you want to know by e-mail and I will respond promptly. I received the photos and they are really interesting, even with my limited knowledge of the CR-39 technique. The cluster was especially interesting--can you tell me on what part of the cathode the cluster was located? The cluster might correspond to where the laser beam spent most of its time. I know where that was but you don't--so this would be a good test. Your paper should be very well received and we wish you good luck.

10/13/2004 (from L.K. --> D.L.)
Dear Dennis: 1) Thanks; the audience at ICCF11 will have no doubt that I am only a self-appointed technician wishing to contribute to your ongoing project. I asked Jean Paul (the conference chairman) to modify my very short abstract. Details will be needed when I start writing the paper, after the conference. During the conference I will focus on pictures and will say that information about cathode #113 will be published by you in the near future.

2) I will be very busy learning as much as I can from the CR-39 tracks. If I knew I had something like this to do I would not schedule my departure to Paris on October 20. I will let you know what I need. Would you be accessible, either by e-mail or by phone during the weekend? That could help me a lot.

3) The most obvious question has to do with differences between the three cathodes. What made your sample 613 different from samples 615 and 616? If possible, please send me a piece of Pd (from the same stock) that has not been used as a cathode. It is essential to show that Pd is not contaminated with something radioactive. The same goes for chemicals you used to make the electrolyte. I would like to cover these materials with CR-39 for several weeks and then look for the tracks. Showing that numbers of tracks due to contamination are negligible, in comparison with those from your cathode 113, would satisfy honest skeptics.

4) In the future I would like to replace the CR-39 with a Si detector of charged particles (similar to that used by Steven Jones but not as sophisticated). Unlike CR-39, it would let us distinguish protons from alpha particles, and to learn about the emission time-dependence. Are we observing something that decreases exponentially or something that has a more complicated curve (first growth then decay)?) We can address this issue later. The biggest task for you would be to produce several highly radioactive cathodes in a row. I hope that generation of excess heat in correlation with emission of nuclear particles will one day be as reproducible as as exposing CR-39 to a radioactive source and observing the tracks.

10/13/2004 (from D.L. --> L.K.)
Ludwik, On August 1st 2004, cell #613 had a boil-off during loading at .1 amps. The cell was in its 5th day of loading

and was well loaded with Deuterium. I checked the cell at 8 pm on July 31st; Scott Little checked the cell the following day, Sunday, August 1st and made the attached entry into the Earthtech online logbook. The cell was NOT instrumented during this event so we can't rule out that the power supply malfunctioned BUT the power supply is of good quality and has been under test since then and has not failed.

Your findings, of course, support the idea that perhaps the boil-off was real and not due to the power supply. It should be noted that the cell top and surroundings were NOT coated with Lithium precipitate after the boil-off, which suggests that the water vaporized very rapidly. The body of the cell got hot enough to melt an epoxy that was holding an external magnet to an aluminum support. This is shown in the first photo, magnet support lying to the left of the cell. Dennis Letts

10/13/2004 (from D.L. --> L.K.)
1) OK--I'll provide what you need. 2**)** Yes, my home and personal lab phone is.....Call anytime, day or night. **3)** Cathode #613, #615 and #616 were all made from the same stock following our 17 step protocol exactly. The electrolyte was prepared in the same way and from the same materials. The cells were loaded and run in the same way. I will send an unused cathode and Lithium from the same stock today. I don't have any unused D_2O from the runs. It should be noted that a few drops of Cravens #1 sauce was added to #613 but NOT to #615 and #616. I will send some #1 sauce for CR-39 analysis.

Results from runs: **#613** -- During loading at .10 amps, 3.3 volts cell #613 had a boil-off event. The cell was NOT instrumented at the time but was loading quietly in a controlled temperature enclosure at about 15C. Cathode was reloaded with Deuterium and tested. No excess power was observed after the boil-off during loading. The details of this boil-off have been sent in a separate e-mail. **#615** - Loaded normally without a boil-off and showed no signs of excess power. **#616** - 10 hours into loading at 3.3 volts, .05 amps, #616 had a boil-off and was partially instrumented. The boil-off caused the cell parameters to go out of range for the existing instrumentation BUT it appears that the power supply did fail the second time. However, this time there was evidence of Lithium precipitate on and around the cell. This IS consistent with a slower boil-off condition possibly caused by the power supply. #616 did produce up to about 250 mW of excess power with an isoperibolic measurement but no excess power by flow measurement.

**an explanation: We are using two calorimeters. One is called the Avanti, which is just a temperature controlled enclosure and is ONLY an isoperibolic system. The second system is called MOAC and is a high-precision dual method calorimter (flow and isoperibolic). We usually load in the Avanti and test briefly with the laser. We then put the cell in MOAC for detailed testing. Both boil-offs occurred in the Avanti system.

4) OK, we will do our best [to perform reproducible experiments] ..... Dennis

10/13/2004 (from L.K.. --> D.L.)
You wrote: "Cathode 613, 615 and 616 were all made from the same stock following our 17 step protocol exactly. The electrolyte was prepared in the same way and from the same materials. The cells were loaded and run in the same way. . . . " That is a very strong argument. Therefore, do not send anything but the #1 sauce. How can an honest scientist refuse to rule out a possibility of contamination of the cathode or the electrolyte after reading the above? One cathode produced practically no tracks. The possibility that my CR-39 pieces was contaminated can also be ruled out; all tiny pieces I used were cut from the same 1" by 1" radon detection chip. More later.

10/13/2004 (from D.L. --> L.K.)
Ludwik, I shipped the remainder of the #1 sauce in the original bottle; there are a few milliters left, hopefully enough for your analysis. It will arrive Friday by UPS. . . .

10/13/2004 (from L.K.. --> D.L.)
Was this sauce dissolved in the electrolyte or was it used as an electrolyte? If it was dissolved in water (together with other chemicals) then what was the concentration of the sauce? Does it mix well with water?

10/13/2004 (from D.L. --> L.K.)

I added about 1/4 of a small pipette to the cell on the last day of the experiment; the cell contained 100 mL of .7M LIOD. I estimate that I added at most about 1/2 mL to the cell. The elements in the sauce are written on the bottle containing the last of the sauce. The sauce was provided by Cravens; if you have detailed questions about the sauce e-mail him directly. The sauce mixed very well and very quickly--one would think that both sides of the cathode were plated about equally. A pair of external permanent magnets were around the cell during the entire experiment--I don't know if or how that would affect the plating process.

= =

There will be more messages but I must stop somewhere. I know that Cravens and Lotts were at the 10th International Conference on Cold Fusion. But I do not remember talking with them privately. Trying to find out who they are I found what they wrote about themselves. At his home page: Cravens wrote: “I am a ‘semi-retired’ college Prof (Physics, Chemistry, Biology and Math -- Yes all 4) who is now teaching a few online college classes for ENMU [Eastern New Mexico University] and SCU [Santa Clara University, California]. But my real ‘love’ is to work on things that might make the world a better place.”

I suppose that Letts, who is probably in his fifties, is also a teacher of physics and chemistry. In one of his e-mail messages he wrote: “I have performed the CF experiment thousands of times and have observed the excess power/heat effect many times; HOWEVER I am not convinced that the effects were real. I have spent 7 years improving my calorimetric skills and perhaps soon I will be able to discern fact from artifact--but until then I won't be ready to ‘move on.’ "

I also found this: “Letts and Cravens have been trying to present a credible cold fusion experiment at EarthTech for 8 years. ICCF10 demo experiment #602 finally convinced EarthTech to build a special dual-method calorimeter to test the laser effect to a higher standard than has been used previously. Letts and Cravens will work closely with EarthTech over the next several months to perform a series of experiments in a high performance calorimeter called MOAC (mother of all calorimeters). If the laser effect appears in MOAC, then cold fusion credibility will be enhanced.”

183) Rough numbers

Ludwik Kowalski (October 14, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Here are some facts concerning observations described in the unit #182. I plan to add additional comments at the end; please revisit.

1) Using CR-39 to detect alpha particles from radon is very common. The detector is a transparent plastic plate, typically 1 mm thick. Alpha particles create latent tracks and these tracks become visible after etching the plastic for several hours in the 6.5 N solution of NaOH at 65 degrees. After that tracks can be observed through an ordinary microscope. I am using a microscope that has a digital camera able to capture pictures. The field seen with the naked eye is circular (for example, the diameter of 5 mm at the lowest magnification 40). But the field seen through the camera, on the monitor, is smaller. In my case it was 1.3 mm by 0.88 mm at magnification 40 and 0.26mm by 0.18 mm at the magnification 200.

Figure 1 Typical tracks from an 241 Am souce; magnification 200

Figure 2 Typical tracks from a Pd cathode ; magnification 200

The two figures above show tracks of alpha particles from ^{241}Am (mostly circles) and tracks from the cathode #613 (often comet-like). In both cases the magnification was 200. Only small sections of photographs are shown to keep the graphic files short. Note that to scan the entire 10 by 5 mm cathode, at that magnification, would require 1100 fields. After realizing how much work is required I selected several fields randomly and counted numbers of particles. These results were then extrapolated to obtain total numbers of particles on the six CR-39 chips exposed to both sides of three cathodes. The numbers given below are likely to be reliable within the factor of two or three.

CR-39 facing the more active side of the cathode 613 (exposure time 820 hrs):
Total area of about 50 mm^2. The highest track density, probably the cluster where the laser beam was intercepted, was close to 6000 tracks/mm^2 (or about 500,000 tracks in the entire cluster). The number of tracks outside the cluster is about 20000. The density distribution outside the cluster was not uniform on the entire surface.

Figure 3 Tracks outside (left) and inside (right) of the cluster; magnification 40

CR-39 facing the less active side of the cathode 613 (exposure time 820 hrs):
The number of tracks from that side was about 4000 (1000 in the cluster and 3000 outside). That is less than one percent of the number of tracks on the opposite side. The apparent cluster is situated at essentially the same location, with respect to the Pd surface, as the much stronger cluster on the opposite side. Is this only or coincidence? I do not know. How can a 30 mW laser beam intercepted at one surface be responsible for the number of tracks on the opposite surface? The thickness of the cathode was close to one millimeter. It clear that the number of tracks on this surface is about 100 times fewer than on the CR-39 exposed to the more active side of the cathode.

CR-39 facing the more active side of the cathode 616 (exposure time 485 hrs):
The area of this piece of Pd was also about 50 mm^2 but the shape of the cathode was nearly rectangular. The total number of tracks on the surface was about 8000. Their distribution was not uniform; not even approximately.

CR-39 facing the less active side of the cathode 616 (exposure time 485 hrs):
The total number of tracks on that surface was about 3000. Their distribution was also not not uniform, not even approximately.

CR-39 pieces facing surfaces of the cathode 615 (exposure time 266 hrs):
The Pd area was close to 50 mm^2; there were less than 100 tracks on each CR-39 surface. The real background (cosmic rays, radon, thoron, etc.), on a piece of CR-39 that was not exposed to the cathode, would be less than 50, for the entire area. It is reasonably to think that all tracks (on surfaces exposed to palladium) were due to the background.

I was wrong in hinting (in unit 182) that some of the particles were able to pass the CR-39 detectors (about 1 mm thick). My CR-39 are dirty and, in a quick look, I probably took some dirty spots for tracks. But Pd particle tracks are definitely different from those due to alphas of ^{241}Am. My guess is that nearly all of them are "born" on the surface, they do not come from the depth of Pd. How else can one explain a relatively large number of tracks looking like comets (not like circles). My etching time of 6 hrs (perfect for alpha particles from my ^{241}Am source) was too long for shallow tracks. Many tracks might have been dissolved by the hot NaOH. If I had to do this over again I would etch for only 2 hrs, examine the tracks, etch for another 2 hrs, examine the tracks, etc. Very tedious, indeed. It would be much easier to use Si detectors, instead of CR-39, as Steven Jones does.

Comments and additions, made after October 14, will be appended below.

10/15/04:
Dividing 500,000 tracks by 820 hours one gets about 600 tracks per hour. This is much higher than several tracks per hour observed from the TiDx foils by Jones. But even this would be too little to generate measurable amount of excess heat. On the other hand, the unusual excess heat event occured on July 31. This was several weeks before I received the cathode #613. Perhaps the ~500,000 tracks from that cathodes is nothing in comparison with what would be recorded if the CR-39 detectors were applied much earlier. My assumption that the nuclear activity was constant during the entire 820 hours can also be questioned. And I have no idea how many shallow tracks might have been desoved in the hot NaOH.

10/15/04 By Steven Jones:
Dear Ludwik and Dennis and Dennis:

The CR-39 results achieved and posted by Ludwik, using the Dennis**2 Pd foils, are very intriguing indeed. Congratulation to all!! Ludwik, I suggest you post the thickness of the Pd foils on the latest posting, as this would affect the ability to see tracks on both CR-39 plates. Also, I certainly agree with Ludwik that follow-up tests using silicon (ion-implanted) detectors would be extremely useful. With the Si detectors available now at BYU, we can determine both the energy and identity of the particles. Seems this should be done right away. And I agree with Ludwik also that the Pd plates should be looked at as soon after excess heat observation as possible. With a Pd foil on the "outside" of a cell, that is, as a wall, we can even put an energy-dispersive Si detector right next to the Pd (in air or helium to allow alphas to get to the detector more readily) -- and thus hope to catch emanated particles DURING excess heat production! This would really clinch it!

Anyway, I share Ludwik's enthusiasm and hearty congratulations to Dennis and Dennis and Scott. (PS -- Is the MOAC giving results yet? I'm very much looking forward to these... I may be convinced yet of correlated heat and particle production...)
--Steven Jones

10/15/04:
The thickness of Pd was 0.42mm. Let me remind you that MOAC, in Steven's message, stands for Mother Of All

Calorimeters. I am sure it will be fully described for us by two Dennises at the end of this year. A very short description was already made in unit 182.

In my first comment above I referred to 600 tracks per hour. Note, however, that for the 20,000 tracks outside the big cluster (cathode #613) one gets 24 counts per hour. This is much closer to what was occasionally observed by Steven, if I remember correctly. Perhaps there are two kinds of cold fusion tracks, those due to the 30 mW laser beam and those that would be present even without the 30 laser beam.

10/15/04 By D2 (Dennis Cravens, not Dennis Letts, D1, with whom I corresponded.):

I would be very much in favor of having Steve get an energy distribution on the electrodes. And then at the end, perhaps an XRF from Scott and perhaps an elemental analysis from Ed.

I am uncertain right now if the sauce sent to Letts several years ago had U in it. I think it is the same one that Scott originally did the XRF on (see below) last year. I would be very cautious on making too much of the counts until we are sure about any U contribution. (my guess is U alphas will be easy to ID). However, as said before, the interesting thing to me is the variation from side to side and area to area on the electrode since any plating should be nearly uniform across the plate and from front to back of the electrode.

If it is the sauce I think it is, it has Ce, Er, Rh, U, Li, Pd and La and a little Hg - The idea at the time was to incorporate high nuclear spins and high quatrapoles for spin exchange to the lattice and then seal with Hg or Au and to have point defects in the lattice for phonon exchange. However, I think it is mostly Pd and Li with some sulfamic acid to keep ions in solution.

[The XRF stands for the X-rays fluorescence. One bombards a sample with photons of 60 keV and observes characteristic photons of lower energies (soft x-rays) due to deexitations in different elements. As one can see below, the spectrum has two tiny picks identified as uranium. In the next comment D1 reminds us that the "sauce" was added to the electrolyte for the cathode #613 only. Is it possible that uranium was subsequently deposited on Pd surfaces? Yes it is. But why would most of the uranium be deposited on a small part of one surface? I do not know.]

Figure 4; the XRF spectrum sent by D2

10/15/04 By D1 (Dennis Letts):

Steve, Thanks for your interest and enthusiasm. As I told Ludwik, #613 was spiked with a small amount of Cravens sauce #1 during electrolysis and that may be the source of the large number of counts. I sent the remainder of the sauce to Ludwik and hopefully he will be able to make an estimate of how much the sauce influenced the high counts on #613. The other two cathodes did not receive any Cravens sauce, so the elevated counts on cathode 616 may be valid.

So far I have failed miserably in MOAC: Scott and his colleague, George Luce, have designed and built a splendid machine and their cooperation has been "over the top." Our plan was to see the laser effect isoperibolically in MOAC and then observe the mass flow measurement a few minutes later, since MOAC was designed to be a dual method calorimeter. If the flow measurement showed a similar response to the isoperibolic measurement, then we would conclude that the signal was real. Failing to see a flow confirmation, we would conclude that the signal was false.

I never contemplated that we would see NO signal. A possible reason is this: I ran out of my old stock of Palladium before beginning the MOAC tests. Cravens and I thought that our methods would work for any metal source but that may not be true. We are presently testing other Pd, Lithium, Gold, D2O sources in an attempt to re-establish the effect so that MOAC can judge our results. As McKubre has said "there's a demon in these experiments". Any analytical help from you, for my part, would be welcome...hope you and your work are well,
Letts, Cravens and the Earthtech group.

10/15/04
I just received the "sauce #1" in a little bottle; about 1 mL. In unit 182 Letts wrote: "I added about 1/4 of a small pipette to the cell on the last day of the experiment; the cell contained 100 mL of .7M LIOD. I estimate that I added at most about 1/2 mL to the cell. ....." Thus the worse possible scenario is that all the uranium from the 0.5 mL of the sauce was deposited on one Pd surface. To simulate this (at the reduced scale) I deposited 0.1 mL of the sauce on a sheet of plastic and dried it on my desk below the 60 W light bulb. The sauce in the bottle did not look like a solution, it looked as a colloidal suspension. The dry layer is probably as thick as the range of alpha particles of uranium. I will measure the thickness in mg/cm^2 eventually. A piece of CR-39 was placed over the dried spot (same shape and same area as the Pd 613 cathode). I will see how many tracks will be created in CR-39 after several weeks of exposure.

10/15/04
David Dow (from..... ?), who read this unit, used my Figure 3 (see above) to produce a density distribution chart shown below. His specialty is GIS (Geographic Information Systems) and he has software for creating density maps. I think that Richard Oriani also used this kin of mapping to analyze cascades of tracks on his CR-39 detectors. His paper on massive cascades of tracks (in the air above the electrolyte) was presented at the ICCF10 last year. It can be downloaded from library at

http;//www.lenr.canr.org

Oriani, as far as I know is the only researcher who also saw cascades of incredibly large numbers of tracks. I am going to work with him after the ICCF11. The goal will be to develop an experiment that can be performed by high school students.

Figure 5 Density distribution map produced by David Dow.

10/16/04
I just realized that I am actually conducting two tests on the uranium hypothesis. I will call them "thick source test'" and "thin source test." The first one was described in the piece above; it involves the "sauce #1." The second test started when the Pd-613 was sandwiched again. Suppose a thin layer of uranium, deposited on the cathode is responsible for the observed 500,000 tracks. In than case I should observe the same number of tracks again. The half-life of uranium isotopes is very very very long. The alpha radioactivity may actually increase due to an accumulation of daughters.

If the number of tracks observed from the thin source test is negligible, in comparison with ~600 per hour, then the idea of uranium contamination could be put aside. But suppose it is not negligible. This should not be taken as a conclusive validation of the hypothesis. But would be a very strong indication that the hypothesis is valid). If this turns out to be the outcome of the test then I would ask for your permission to send the cathode to Steven Jones. The energy spectrum of alpha particles from uranium, and its daughters, are well known. If the observed spectrum matches known peaks of uranium than we would say that uranium was indeed responsible for our excitement. I am assuming that Steven would be happy to conduct the decisive test with a Si detector.

Modified on 10/17/04
Let me add one more observation. Some say that cold fusion people are con artists. Are we con artists? A con artist would hide everything that might cause doubt about his claim, he would focus on convincing arguments only. But the idea of a possible uranium contamination came from Dennis Cravens. He tells us not to accept the results from Pd-613 before further testing. I agree with this. His observation about Pd-616 (11,000 tracks) is also valid. Dennis's experiment was designed to confirm the reality of cold fusion; how can he remain objective in the face of an apparent confirmation? But he is saying to us "hold your horses". That this fact is very significant to me, in the context of the cold fusion controversy. Dear Dr. Park, are you reading this unit? I would be happy to append your comment below. Do you think that what dennisses do is voodoo sciece? Will I see you at the ICCF11 event or are you going to boycot it?
End of modification.

I was tempted to ask D1 and D2 about their motivation for adding the "sauce 1" into the electrolyte. I did not ask

because they decided to wait till December 31, the date of the announcement. The answer came, quite unexpectedly, from Steven Krivin who interviewed D2 before writing a new book on cold fusion (see item 181). During the interview Steven asked: "Can you describe your work in layman's terms?" The answer of Dennis Cravens was: "Right now I'm doing work with Dennis Letts, who's doing laser induced reactions, trying to stimulate the surface and get surface reactions going. Also, chemical excitation of a palladium cathode. And putting in special chemicals within the mix and then electrolyzing and then kicking off the reaction through a new surface applied to the palladium." That is good enough for me, at least for the time being. To see the entire interview go to:

http://www.newenergytimes.com/Conversations/cravens.htm

10/18/04 from Steven Jones to D1 and D2.
Thanks for the additional – and very important—information. As D2 noted, “I am uncertain right now if the sauce sent to Letts several years ago had U in it. I think it is the same one that Scott originally did the XRF on (see below) last year. I would be very cautious on making too much of the counts until we are sure about any U contribution. (my guess is U alphas will be easy to ID). “ This is just the sort of thing we need to do – check and re-check ourselves!

Note that an advantage of the dual-coincidence spectrometer here (which includes a cosmic-ray veto) is that we are not sensitive to alphas from uranium – or radon, etc., since a coincidence is required, such as proton + triton from d-d fusion. (Another example is alpha + alpha from d-Li6 fusion.) We would miss events in which single nuclear particles are emitted. And we did see a signal from the foil D2 prepared last year when placed in our dual-coincidence spectrometer. I wish you the best of progress and success with the MOAC. To me, an instrument such as this has great promise in unraveling the mystery of “cold fusion.” 10/19/04 My message emailed to D1 and D2: A nuclear physicist, and a friend, who is very skeptical about cold fusion, asked: "How pure is your palladium? Are you sure that palladium does not contain naturally a minute intrinsic admixture of thorium or uranium?" Well, one can find atoms of any anything in a manufactured object. The issue is how many. This question of impurities is likely to be asked by others. The XRF spectrum sent to me by D2 does not have any numbers (ppm?) along the vertical axis. Do you have manufacturer's specification of impurities? If so then I would like to have it in Marseilles. Let me summarize this issue of contamination.

1) According to D2, who was the first to say "hold your horses," the sauce #1 might have contained some uranium. To back this hypothesis he showed the XRF spectrum with two tiny peaks attributed to uranium. He is not certain that the sauce (~0.5 mL) actually added to the electrolyte (~250 mL) was the same as that used in the XRF analysis. Therefore, a possibility that the sauce actually used was even more contaminated should not be excluded.

2) Two tests for contamination with an alpha-radioactive source are in progress. Waiting for the result one must rely on the following reasoning (speculations).

a) One line of reasoning goes like this: "The Pd-615 cathode was made from the same stock as the Pd-613. Both cathodes were processed in exactly the same way. The Pd-615 cathode did not produce tracks. Therefore, palladium itself, or the electrolyte, were not contaminated."

b) Another line of speculation goes like this: "Contamination from the electrolyte would lead to essentially the same number of tracks on both surfaces of Pd-613 due to the geometry of electrodes (Pd cathode surrounded by the spiral Pt anode). But the numbers of tracks produced were found to be very different on two surfaces."

c) Contamination of the original Pd, or contamination of the electrolyte, could not produce a highly localized cluster discovered on the Pd-613 cathode. Why would the size of the cluster, and its location on the cathode, coincide with the location and the size of the laser beam?

d) An apparent correlation between the number of tracks observed with three cathodes and the excess heat they generated is based on three cases only. It can be a matter of coincidence. I am referring to is this: Pd-613 --> a lot of tracks and a lot of excess heat, Pd-616 --> much less tracks and much less excess heat, Pd-615 --> no tracks (above the background) and no excess heat.

The weakness of the first three arguments is that the contamination might have been introduced when the Pd-613

cathode was handled. It is not totally impossible that such contamination occurred on one of the Pd-613 surfaces, and exactly at the same place where the laser beam was later intercepted. That is why the outcome of the ongoing "thin source" test will be so important. I just calculated the amount of U-238 needed to emit 500,000 alpha particles in 820 hours. That amount would have to be only 0.14 micrograms. Assuming that the CR-39 detects one half of alphas (the other half is emitted into the opposite direction) the amount would be due to 0.28 micrograms of uranium. On the other hand, uranium is likely to be mixed with its alpha-radioactive daughters. In that case even 0.05 micrograms could be sufficient to produce the observed tracks. The mass of Pu or Am, needed to produce 500,000 alphas in 820 hours, would be many orders of magnitudes smaller than what was calculated for the U-238.

10/19/04 A reply to the above from Dennis Cravens:
The Pd used, that you have is four 9's .....99.99%. Many other researches in CF have very well characterized Pd. The most sensitive way to check for U or Th is via neutron activation of a sample. We don't do that but others have. U and Th is not at all likely to be in quality Pd. I prepared four sauces for Letts. Only one had U and it is the one that you have the XRF of. I just do not know which one is the one he used in that experiment. In the case of treatment of Jones' Ti (though I am not sure you have that one) no U was used only La. The bottom line is that the sample you have is either the same as the one that the XRF was done on or it has no U at all. It cannot be the case that it has more U than the XRF sample.

10/19/04 Additional details from Dennis Letts:
This metal was provided by Scott at Earthtech International. The metal may be nearly a decade old. The metal is: "Premion" Palladium foil, 1mm thick, 99.9975% purity (metals basis), stock # 12056, lot# w25022. Seller: Alfa Aesar, 30 Bond St, Ward Hill Ma 01835 800-343-0660. I called Alfa Aesar a few minutes ago and they will look for a spec sheet on the metal but they said the lot number was old and they probably would NOT have the data. I do have plenty of the metal left for analysis, so if purity becomes an issue then we could have it analyzed by a recognized lab.

10/19/04
I think that the most sensitive method of testing for an alpha emitter of a surface is detection of alpha particles. A negative outcome from our "thin source" test, already described above, would be a definitive proof of "no contamination." Revisit this page on November 14 to see how many tracks were found on the CR-39 exposed to the suspected Pd-613 surface for one month. It should be close to 500,000, if uranium is responsible. I would be nearly certain of contamination in such case; to be 100% certain one must show that the energy spectrum of particles matches the known spectrum of uranium. We will see.

10/20/04
One possibility of contamination has been ignored so far. How can you be sure, a person with a healthy dose of skepticism might ask, that the Cr-39 used was not contaminated? My answer would be "all seven pieces of CR-39 were cut from one larger piece. Why would only one of them be contaminated?" But once again, this argument belongs to logic; my answer should be based on a test. Perhaps the contamination took place after the original piece was cut. Here is what I am going to do, right now. I will expose the CR-39 surface, that produced tracks shown in Figure 2, to a fresh CR-39 detector. If the surface is contaminated then the fresh detector will show tracks resulting from contamination. The result will also be shown here on November 14; please revisit. I know that I will embarrassed if contamination is found. It would be a lesson; one should not claim anything important without conducting all the necessary tests. But not announcing a tentative conclusion would deprive me of readers' constructive comments.

184) Three weeks later

Ludwik Kowalski (November 11, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

As reported in the unit #183, three cathodes (Pd613, Pd616, and Pd615), obtained from the Texas group of D. Letts, were examined with CR-39 detectors. The purpose was to look for possible presence of charged particles (such as those observed by S. Jones et al.). The results were exciting:

1) A very large number of tracks were observed in the CR-39 detectors exposed the Pd613 (much more on one side than on another).

2) A large number of tracks were observed in the CR-39 detectors exposed the Pd616; again more on one side than on another).

3) Only background tracks were observed in the CR-39 detectors exposed the Pd615.

After reporting these results (in the unit #183) I was informed that the Pd613 generated a lot of excess heat, that the Pd616 also generated excess heat (but considerably less), and that the Pd615 failed to generate excess heat. Could this be a coincidence? Yes it could. The issue of a possible contamination with a natural alpha emitter was raised. The main suspect became the so-called “sauce #1” added to the electrolyte in which the Pd613 was used. Small amount of uranium were known to be present in that sauce. Note that the sauce was added only to the cell with the Pd613, it was not added to cells with the Pd616 and Pd615 cathodes.

I performed these quick checks for contamination:

Check #1: Several drops of sauce #1 were placed on a piece a plastic and allowed to dry. A CR-39 detector was then applied to the dry spot for nearly 22 days. The surface was covered with tracks that looked like those due to alpha particles.

Check #2: The Pd613 cathode was sandwiched between the fresh Cr-39 detectors for the second time (also for nearly 22 days). Absence of tracks in this test would indicate that the previously reported tracks could not be attributed to contamination of the cathode. A contaminated cathode, on the other hand, would produce as many of tracks as before. Without counting I am inclined to conclude that most of the tracks due to the Pd613 cathode were caused by contamination. But this is not the only possible conclusion. I will write about this later. The questions to be answered have to do with the “one side of the cathode being much more active than another” and with a strongly pronounced clustering of tracks. The nearly-axial geometry of the cell (a small cathode surrounded by a spiral anode) should not produce the sidewise asymmetry if contamination was coming from the uranium in the electrolyte.

Check #3: The two CR-39 surfaces, on which tracks from the Pd613 were discovered, were checked for their possible contamination. The motivation for this test (also lasting 22 days) was to rule out a possible of a coincidental contamination of the CR-39 detector itself with a naturally occurring emitter of alpha particles. The results are consistent with the idea that a substance on the surface of Pd-613 was transmitted to the detector that was in contact with the cathode (for 820 hours during the experiment described in the unit #183). The tracks on the CR-39 facing the more active side of the Pd613 are much more numerous than on the CR-39 facing the less active side of the Pd613 cathode. This is consistent with the idea of “transferring by contact.”

Check #4: The more active side of the Pd616 cathode was exposed to the CR-39 detector for nearly 22 days. The detector revealed numerous tracks, similar to those of alpha particles. These tracks can not be attributed to the sauce #1 (that sauce was used with the Pd613 only; it was not added to the electrolyte surrounding the Pd616 and Pd615 cathodes). Ignoring the case in which the sauce #1 were added to the electrolyte one is tempted to think that a process responsible for charged particles, when excess heat was generated, is still going on. On the other hand tracks due to particles emitted by the Pd616 might be due to an unknown source of contamination. That source was present when the Pd616 cathode was able to generate excess heat and it was absent when no excess heat was generated (the cathode Pd615). As far as I know, the electrolyte used in all three cells was taken from the same bottle. Likewise, palladium cathodes were cut from the same larger sheet of pure metal.

The situation is far from being clear. I would prefer to say nothing at this time. But at the conference in Marseilles (last week) I was describing the ongoing tests and promised to post my first observations. Please consider them to be very preliminary. The most reasonable thing to do next would be to use a silicon detector (and a telescope of two detectors) to measure energies and to identify particles responsible for the tracks.

185) About CR-39 Detectors

Ludwik Kowalski (November 14, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Several people asked me about using CR-39 detectors recently. Here are suppliers of that material that I know about. If you know another supplier then please send me the information about the firm and I will append it to the list below. My e-mail address is; <kowalskil@mail.montclair.edu>.

1) Landauer, Inc. (2 Science Road, Glenwood, IL 60425, USA)
Contact Rose Elza at radon Customer Service
Her phone # is 1-800-528-8327. Her e-mail address is: relza@landauerinc.com
One sheet (for uncut 350 pieces) costs $340. A set of 350 cut pieces (each piece has an engraved ID number) costs $560.

2) Alpha Trak Learning (141 Northridge Drive, Centralia, WA, 98531, USA)
Contact Criag Gabler <radon@alphatrak.com>. Minimum order, $100, covers 100 pieces; each piece is 1 cm by 1 cm.

3) Track Analysis System, Ltd. (H H Wills Physics Lab, Tyndal Avenue, Bristol, BS8 1TL, United Kingdom.)
Contact Peter Fews <Peter.Fews@bristol.ac.uk>
Minimum order for the USA is $500 (it is $100 in Europe). Various sizes (up to 27.5 cm by 28.0 cm) are available. For example, each piece of 2.5 cm by 2.5 cm (1 mm thick) costs $1.75.

4) Intercast Europe S.p.A. (P. Neri, Via Natta 10 / a 43100 Parma Italy
Tel +39 - 0521 - 607555 Fax +39 - 0521 - 607924)
p.neri@intercast.it www.intercast.it

The prices are, for example, 200 euros for the 40 by 70 cm sheet (thickness 0.7 mm) or 300 euros for the 96 by 96 cm sheet (thickness 1.4 mm).

5) Daedalon Corporation (Walter Brown, Daedalon Corporation, P.O. 2028, Salem, Ma, 01970-6228. Phone (978) 744-5310; FAX (978) 745-3065
daedalon@cove.com www.daedalon.com
Five round alpha particles films EN-21 (diameter 8.6 cm) costs $215.

They do not say it is CR-39. They wrote to me: “The film consists of a thin layer of cellulose nitrate coated on a poly ester base. If the film is struck be an alpha particle, it is structurally damaged so that the damaged spot can be etched away in a sodium hydroxide solution. The etched film has clear spots, where it has been struck, with a reddish background. The film has no sensitivity to other radiation.” [They probably mean beta and gamma rays. How can the material not be sensitive to particles produced by neutron radiation?]

6) American Acrylics and Plastics, 300 Benton Rd. PO Box 1045, Stanford Ct, 06497.
Tel: 203-377-0752
Dosimetry CR-39 plastic, $100 for one large sheet (looks like 1 by 1 meter).

7) Fukovi Chemical Industry, Japan.

This CR-39 material was calibrated by A. Lipson et al. (downloadable from the library at www.lenr-canr.org). The calibration consisted of measuring diameters of tracks for monoenergetic alpha particles and protons of various energies. It is valid for one set of specified etching conditions. Tracks due to protons are usually about two times smaller than for alpha particles of the same energy. I will assume that their calibration is applicable to CR-39 from other manufacurers, as the first approximation.

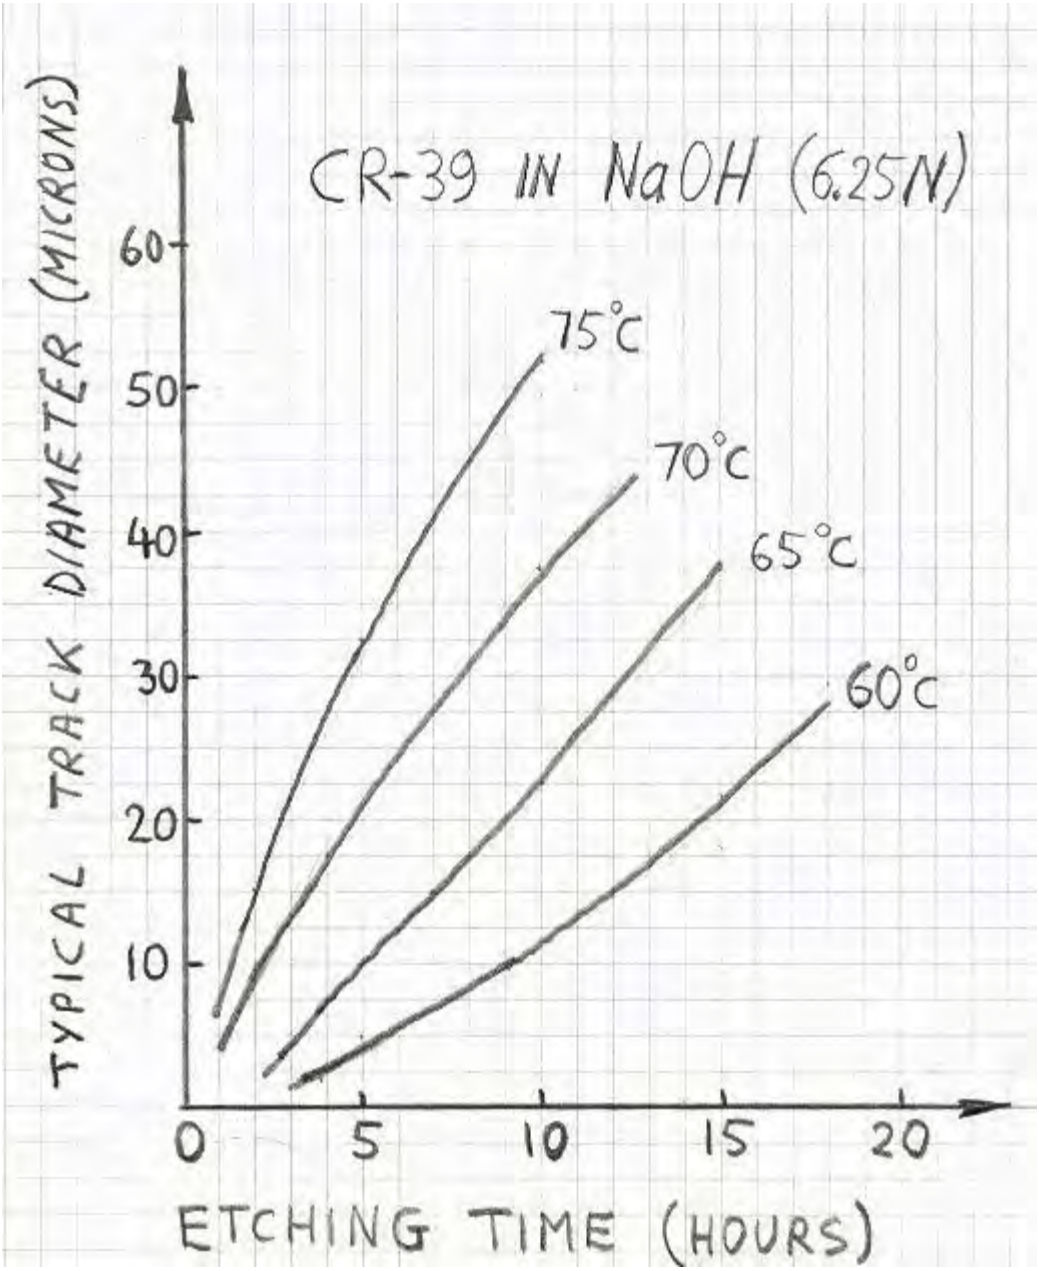
The CR-39 polycarbonate was patented (in 1939?) by an US company Columbia Research. This probably explains the name. Plastic lenses are now made from that material. Another use is detection of alpha particles, for example, from radon. Each particles creates a sub microscopic crater which can be enlarged by etching the plastic in the hot NaOH. After that the craters become observable through an ordinary microscope. Here is a brief description of the use of CR-39, as e-mailed to a friend about one month ago.

" One simply peels off the protective thin plastic from the CR-39 and places the detector (about 1 mm thick) over an object that emits charged particles, such as alphas or protons. The material is not sensitive to electrons. The etching solution is NaOH in water (concentration 6.25 N). Make sure your skin does not come in contact with that solution; if it does then wash your hands at once for at least a minute or two. Preheat the NaOH solution to 65 C and suspend a detector in it for about 5 hrs. Then remove the CR-39 and wash it in water. The NaOH solution etches the surface slowly. At the same time it etches more rapidly along the invisible (latent) tracks of charged particles. That is how tracks become visible. If you etch too long, say 20 hrs, you might take away the layer that contains tracks. If you etch not long enough, say 1 hr, then tracks will be very small. The diameters of circles, due to alpha particles from Am-241, grow about linearly with the etching time (after the fist hour). I settled for six hours. My Am-241 source is from an old smock detector, the radioactive spot is probably covered with something protective. That is why, I suppose, most tracks are circles. Radio Shack sells the radiation-type smoke detectors for about $10."

A very detailed description of various aspects of track detection can be found in a recent review article of D. Nikezic and K.N. Yub. That extensive review was published in "Materials Science and Engineering," R 46 (2004) 51–123. The heading states that the paper is available over the Internet at: <http://www.sciencedirect.com>. In my letter to the friend I continued: "At one time I exposed the CR-39 to a Pu-Be source of neutrons. This produced tracks whose diameters were similar to those from Am-241. They were probably due to (n,alpha) reactions in CR-39. But most tracks had smaller diameters; I think they were due to recoiling protons. A.G. Lipson and A.S. Roussetsky published a calibration curve for the CR-39 from Fukuvi. It shows how diameters depend on energies -- for alpha particles and for protons -- under a specified etching protocol. Their paper can be downloaded from the library at <http://www.lenr-canr.org>

You will need a good optical microscope, preferably with a digital camera attached. Our biology department has such microscope. If you have a choice use a microscope equipped with an objective of low magnification. My lowest magnification is 4 (times 10 from the eyepiece); I would prefer it to be 2. Magnification 20 is fine to examine individual tracks, magnification 2 would facilitate counting of tracks which are rare (because each view is very large). To count rare tracks I would etch for 9 hours. I prefer to count numerous tracks from printed photos (and not from the computer monitor). Using a red pencil I flag the already counted tracks to eliminate double counting. That is about my experience. Google will provide you with more information.

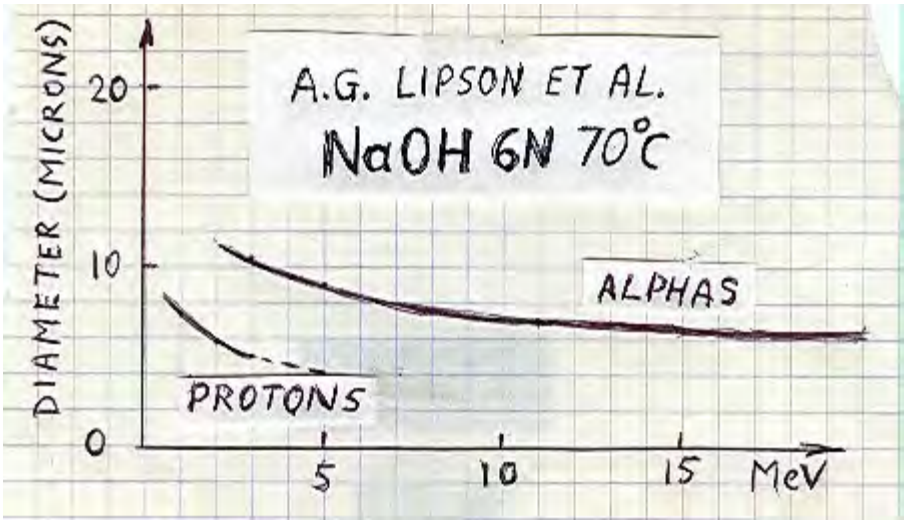
P.S. 12/22/04
After purchassin a large sheet of CR-39 from Fukuvi I conducted a little investigation. Using the 6.25 N solution of NaOH I decided to learn how the diameters of tracks depend on the etching time at four temperature, as illustrated below:



Results of rough measurements

Diameters were measured by using the stage micrometer under the microscopic magnifications of 200 and 400. Typical tracks were selected by inspection. The numbers shown are read from smooth curves.

c) Large diameters (easy to identify) and shorter etching times are desirable but the most important thing is to have as small background as possible. Suspecting that excessive temperatures might produce some track-looking background I decided not to push temperatures. My rule will be 10 hours of etching at 60 C. I looked, without being successful, for the evidence that etching at 70 C increases the number of background tracks. Perhaps shorter etching times at 70 C compensate for the effect of temperature. Most background tracks are real; they are probably due to cosmic protons and neutrons. Radon in air was not allowed to procuce tracks till the sealed envelope was open by me, and till plastic covers were removed. In other words, exposure to alpha particles can be limited to several days, the duration of an experiment. To minimize background due to radon Oriani keeps his open CR-39 chips between strips of masking tape, even when exposure times are limited to hours.



Calibration curves: (CR-39 from Fukuvi) for alpha particles and protons

186) Transmutations of radioactive isotopes?

Ludwik Kowalski (November 15, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

At the last international cold fusion conference in Marseilles (ICCF11, November 2004) I was exposed to new claims that radioactivity can be destroyed very rapidly by microbial and pyrolytic processing. Microbial processing was described by Ukrainian scientists (1) while pyrolytic processing was announced by a businesswoman from Canada, E. Anderson (2).

According to (1), the half-life of ^{137}Cs, known to be 30 years, was reduced to less than one year. This has been accomplished by metabolically active microorganisms. "The process involved transmutation of long-lived active nuclei to non-radioactive isotopes during growth and metabolism of special microbiological MCT." The initial activity of 137Cs was reported as 18,000 bq (0.49 microcuries) and the process was conducted at room temperatures. Measurements of radioactivity, in closed flasks, were made with Ge detectors every five days. Half-lives of ^{154}Eu, ^{155}Eu and ^{241}Am were also affected by microbial action.

Unfortunately, most conference participants were not biologists and the report did not receive the scrutiny it deserves. In my opinion, it should be presented at a conference for microbiologists. It should also be submitted to government agencies responsible for dealing with radioactive waste. They should be interested because ^{137}Cs is a major contributor to radioactivity of spent fuel after it is removed from a nuclear reactor. Ability to transform large amounts of ^{137}Cs into non-radioactive substances would be highly beneficial. My personal reaction to the report was to imagine a metabolic process through which bacteria turn cesium into a gaseous compound escaping from the flask. But I am neither a biologist nor a chemist; the authors of the report probably investigated that possibility and ruled it out on the basis of experimental data.

According to (2), a Canadian company is about ready to start destroying radioactive waste on an industrial scale. She said that the apparatus built for the company is able to destroy 50% of radium, whose half-life is known to be 1620 years, in only 3 days. It also changes thorium into lead. What would Marie Curie think about this claim? She and her husband tried many ways to change the half-life of radium but were not successful. This was about one hundred years ago. According to Coleman (2), the senior science consultant to Monti America Corporation, "With the gradual disappearance of the Ether (Relativity) the Physical Space in which to place the Atom and rebuild its structure also disappears." This strange statement [is there a typing error somewhere in this sentence?] is backed by references authored by R. Monti and G. Monti. Outlining the short history of the transmutation of the waste project Coleman continues: "In 1992 R.A. Monti was given the opportunity to pursue Low Energy Nuclear Reactions at Texas A&M University [with Lin and Bockris]. The goal of the sponsors of this research . . . was to produce noble metals on an industrial scale. This goal was not achieved. The cost of gold and silver produced by transmutation of Lead and Mercury exceeded the ordinary market price. When the Philadelphia Project failed R.A. Monti decided to take another direction in his research. The possibility to cause nuclear fission of stable isotopes by ordinary chemical reactions had suggested immediately that it should also be possible to do this with radioactive materials.

A series of experimental tests made from 1993 to the present have shown that this is indeed the case. Unstable isotopes can be transmuted into stable isotopes. In 1993 R.A. Monti informed the Italian National Research Council about the possibility to get rid of nuclear waste but they rejected the idea. From 1994 to the present, ongoing research has been funded by a group of Canadian companies which ultimately led to the formation of Monti America Corporation in 1998. A proprietary formula for transmuting Lead and Mercury into silver was used as a driver for the transmutation of

radioactive elements. R.A. Monti observed that Thorium . . . can be transmuted into stable elements with 80% success rate, based on total input weight in the right season of the year. [Does the "right season of the year" phrase refer to temperature, humidity, winds, etc. or to factors linked with astronomy?]

During 1995 and 1996 over 50 experiments were conducted . . . The years from 1997 to 2004 have been used to conduct validation tests at independent research facilities and to demonstrate the process internationally. Monti America Corporation is currently working on constructing a pilot plant to prove the commercial viability of the process.

The experimental results of the tests made from 1992 to 1996 were so astonishing that they were by and large rejected out of hand by the scientific community. As a matter of fact the papers . . . do not appear in the Proceedings of these [Cold Fusion] Conferences (rejected by Ikegami, Passell, McKubre, Fleischmann) . . . In 2000 (ICCF8, Lerici, Italy) the paper . . . was rejected by Scaramuzzi (13). Finally, the paper was published in 2004 by Hal Fox (6)." My attempt to obtain a general explanation of the proprietary process from Monti, who was present at the conference, produced nothing more than a statement that the process is "pyrolytic." I remember that this term was used by Bockris, a recognized authority in electrochemistry who was the first to report cold fusion transformations.

By the way, I was not aware that Monti's claims were rejected by leading cold fusion researchers. This fact , however, did not prevent a company from investing heavily in Monti's technology. I talked with Mrs. Anderson and with the president of Monti America Corporation. They are not scientists. But they are totally convinced that their large investment will soon become profitable. To begin with, the company plans to concentrate on low level radioactive waste from petroleum products, and from other industrial operations. They plan to move to highly radioactive waste later. I said that I would like to come and observe the pyrolytic device in operation. They said that they would invite me, probably in several weeks. I hope this will happen; I would be happy to write a unit on the first industrial application of what is, according to Monti, a cold fusion transmutation process. Will they allow me to make some measurements? This remains to be seen. Will they be able to destroy the waste ready to be stored under Yucca mountain? Probably not.

I am convinced that destroying highly radioactive waste by neutrons (from a very strong spallation source) is scientifically possible and practically desirable. This, however, has nothing to do with approaches based on microbial activities or on a pyrolytic process. My advice to potential investors is to wait until such processes are confirmed by recognized experts. Biological experiments with radioactive substances are very recent and scientists performing them are not promising anything useful, as far as I know. The technology developed by Monti, on the other hand, is a promise of something useful. But that promise, as indicated above, is not taken seriously by recognized experts, even within the cold fusion community. That situation would certainly change if Monti America Corporation suceeded in destroing (rather than dispersing) even on radioactive isotope.

The presentation of the paper (2) ended with the following statement. "We have been asked not to release the full details as this involves a private research project on the verge of becoming a commercial interprise. We have been, however, authorized to attach a letter of opinion from a Canadian learned society which gives a general summary of the demonstration." Before showing that letter (see below) let me mention a videotape of the demonstration; it was shown at the conference. I was not convinced by its content. Three other existing videotapes were mentioned in a handout:

1) "Gold from Mercury according to Gabber," by R.A. Monti and G.A. Cesarano Monti.
2) "Gold (light and energy) from Naples," by D. Cirillo and V. Iorio.
3) "Transmutation of nuclear waste in Stockholm" by Monti America Corporation

I hope the contents of these tapes will have more scientific information than the videtape shown at the conference. What follows is the July 24, 2004 letter from the Canadian learned society (The Planetary Association for Clean Energy, Inc.) to Ernest Bauer, President of Monti America Corporation. The abbreviation NORM/NONS, in that letter, stands for Naturally Occuring Radioactive Materi/Naturally Occuring Radioactive Substances.

Dear Mr. Bauer,
The following constitutes our opinion about your achievements to date associated with Monti Process and its application within your Kamloops, British Columbia facility.
As you know, our Association, the Planetary Association for Clean Energy, Inc., is a Canadian learned society that has

developed an international, independent, collaborative network of advanced scientifIC thinking since 1975, under the leadership of the late Canadian scientist Senator, the Hon. Chesley W. Carter.

Our network has been peer reviewing, extensively, and on an international scale, progress with the Monti process, since the 1990s. We continue to do so and consider it as one of the top systems worldwide for the rapid, affordable and efficient decontamination of a variety of nuclear waste materials, including NORM/NONS (which are, as you know, present in rocks, soils, building materials, consumer products such as fertilizers, and a variety of by-products of such common technological activities as the petroleum, the fertilizer, the pulp and paper and the mining industries). Recently we made a presentation before a Canadian Senate Committee, which was received with considerable interest, supportive of the Monti Process for widespread application throughout Canada.

In a step of a series of review procedures that our network has taken to review and facilitate the Monti Process * (footnote), we have attended, in the form of several of our members, and have followed a number of demonstrations and controls in May of this year at the newly established Kamloops facility.

*(footnote) The Monti Process has been tested many times in the past, including at ENEA, the Italian National Agency for New Technology, Energy and The Environment, at the Royal Institute of Technology and Science in Stockholm, Sweden, in Taiwan, and at a previous demonstration in Kamloops, B.C., all of which were monitored by independent scientific observers. In all instances, the results were positive, demonstrating that the Monti process could effectively deplete the radioactivity by up to seventy five percent within three to four days. *(end of footnote)

This facility was established for the purpose of rapidly depleting Naturally Occurring Nuclear Substances (NONS) with the Pyrolytic Monti process. Present at this demonstration as independent scientifIC observers were: John Coleman, BS, MS, Ph.D., Massachusetts Institute of Technology (retired) Domina Eberle Spencer, Ph.D., University of Connecticut Andrew Michrowski, Ph.D., President, The Planetary Association for Clean Energy, Inc. Monique Michaud, M.ScA, CGD, The Planetary Association for Clean Energy, Inc. Mark Porringa, P. Eng., Atomic Energy Canada Limited Philippe Duport, Ph.D., Director, Institute ofthe Environment, University of Ottawa John R. Johnson, Ph.D., IDIAS Inc., University of British Columbia Trevor Beniston, P. Eng., Stuart Hunt & Associates (radiation safety consultants, petroleum industry)

During the May 2004 demonstrations, gas mantle ash containing thorium oxide was used as sample for the rapid reduction of radioactivity. The radioactivity level was reduced by over 50% within 3 days. Measurements for the radioactivity were obtained with sophisticated, state-of-the-art monitors, under fIXed, pre-determined geometric configurations to ensure valid comparisons between measurements made on input material and after the Pyrolytic reactions. The remaining radioactive materials were processed a second time to obtain further depletion of radioactivity.

The independent observers confirmed that no deleterious gases escaped and that the remaining sludge is essentially inert. The metal buttons that remain after firing and cooling are totally inert within 4 days after firing.

We conclude with the recommendation that the Monti Process facility in Kamloops is ready to commence processing radioactive filters from the petroleum industry. We understand that Dr. John Johnson, nuclear safety expert, is currently advising his contacts in various committees, including the ANSI-N13 committee, which is developing a standard for Technically Enhanced Naturally Occurring Radioactive Materials (TENORM) as it affects the radioactivity issue associated with gas and oil production filters. He, being deeply aware of the Monti Process, is indicating that the industry may now submit filters for "ashing", for a practical-size "start-up" run at the Kamloops facility.

We are pleased with the cleanliness, simplicity and rapidity of the process that is now in place for dealing with various NORM/NONS - truly a world first.

We also concur with Dr. Johnson's position regarding the readiness of your facility to deal with certain types of radioactive wastes, indicating that it is in an unique position to resolve the storage problems for the petroleum industry NORM/NONS as well as a solution to eliminate the long-term liability to the industry. The widespread application of the Monti process, in our view, will contribute to the safeguarding of the environment for both present and future generations.

We haw no objection to your showing this letter of opinion to potential users in the hopes that they will consider the advantages offered by the Monti Process and your facility.

Yours sincerily,
Dr. A. Michrowski,
President

1) V.I. Vysotskii, A. Odintsov, V.N. Pavlovich, A.B. Tashirev and A.A. Cornilova; “Experiments on controlled decomposition of water mixture of different long lived active isotopes in biological cells.” That was a paper presented at the ICCF11.

2) E. Anderson, from Monti America Corporation was reading (at ICCF11) a paper of J.W. Colman, R.A. Monti and G.A. Cesarano Monti: “Transmutation of nuclear waste by low energy nuclear reactions.”

P.S. After posting the above I went to Google and typed “Roberto A Monti” This generated a lot of items worth reading. They show the scientific side of Monti. I hope that his contribution to mankind will be real. But I am glad that my money is not invested into his technology. The rule should be "science first, costly applications later." Yes, I know that this rule has often been violated. That is why I remain open-minded.

187) Role of magnetic monopoles, etc.

Ludwik Kowalski (November 15, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

At the last international cold fusion conference in Marseilles (ICCF11, November 2004) I was exposed to new aspect of cold fusion -- magnetic monopoles. Several papers, both theoretical and experimental, were devoted to that topic. I will not comment on these papers because I know very little about magnetic monopoles (1). But one thing is clear -- explaining one mystery in terms of another mystery is not very convincing. As stated by one cold fusion researcher (in a private conversation) this approach is just the opposite from what is widely known as Occam's razor approach.

According Russian and French scientists (2), the Chernobyl nuclear plant explosion was caused by "the impact of a strong magnetic field" (monopole). Such fields, acting on the beta-radioactive fission products, inside the reaction core, decreases the rates of decay of these products. This, in turn, increases the rate of emission of delayed neutrons. Delayed neutrons play an essential role in the control of the reactor. The authors think that "the official explanation of the accident does not seem to be satisfactory." They suspect that the new (monopole) explanation is deliberately suppressed because a large number of existing reactors would have to be closed to prevent similar accidents.

Likewise, according Russian and French scientists (3), the explosion of the French ammonium nitrate plant near Toulouse might have been caused by a magnetic monopole. That 9/21/2001 explosion killed 31 people and resulted in 2500 injuries. The authors state that "in the near neighborhood of magnetic monopoles the magnetic field is in the range of 100,000 teslas." The role of magnetic monopoles in cold fusion was also discussed by a theoretical physicist from Japan (4,5). Another theoretical consideration, related to the above hypotheses (accidents in chernobyl and in Toulouse) was Russian scientists (6,7). The authors show that atomic nuclei can be stable in neutral atoms and instable (K-capture decay) in fully ionized atoms.

Another paper belonging to the category "new to me" was presented by a scientist from Belarus (8). The author thinks that familiar reactions of fusion and fission are 'neutrino-driven." This claim is said to be supported by the experimentally observed correlation between the radioactive decay rates and solar activity. The effect of chemical environment on decay rates also illustrates this point of view. The author informs us that the rates of decay of ^{137}Cs, produced in the Chernobyl accident, were observed to be reduced very considerably in the fallout samples. He also informs us that the "so-called torsion radiation" was observed triggering nuclear transmutations.

188) Oriani cell effects

Ludwik Kowalski (November 22, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

I just returned from a "field trip" to Oriani's lab at the University of Minnesota (UM) in Minneapolis. Who is Richard Oriani? He told me: "my mother and father were both born in El Salvador as I was. He was of Italian descent, and she was of Spanish descent." The family immigrated to the US in 1920s. Richard was born 84 years ago; he thinks he is the oldest active cold fusion researcher. He is also a veteran of the field, exploring it since its very beginnings in 1989. Few were as well prepared for such work as he was. A metallurgist with a Ph.D. in physical chemistry from Princeton, he was, for many years, a director of a large anticorrosion institute at the UM. I met him for the first time at the 2003 cold fusion conference (ICCF10). He and Fisher presented two papers describing the use of CR-39 detectors to detect showers of nuclear particles in the liquid and above the liquid of a running electrolytic cell. That inspired me to start using such detectors. We corresponded by e-mail (see unit #108 at this website) and at one point -- it was several months ago -- I asked if he could help me design a simple and convincing cold fusion experiment for teachers and students. He agreed and last week's trip was the result of that invitation. I wanted to see the experiment with my own eyes.

Oriani has several electrolytic cells. I will describe just one of them. He calls it a "vertical cell;" I will refer to it as an "Oriani vertical cell." It is essentially a glass tube whose bottom (cathode) consists of a metallic foil, for example nickel of 0.125 mm. The tube is half-filled with a solution of Li_2SO_4 in ordinary water. The anode, made from a platinum wire, is inserted into the solution from the stopper, at the upper end of the tube. That stopper has an opening; its purpose is to allow oxygen and hydrogen, produced during the electrolysis of water, to escape into the atmosphere. The electrodes of the cell are connected to a power supply (about 5 volts) and a current of 0.2 amperes is allowed to flow. Nothing unusual so far; it is a simple electrolytic cell producing oxygen and hydrogen from water. Several anomalous effects were discovered with this device. I will refer to them as: (a) Oriani liquid effect, (b) Oriani vapor effect and (c) Oriani solid effect. I was privileged to perform experiments demonstrating each of these effects. Papers (1,2) describing the (a) and (b) effects have been available on the Internet for more than one year. The (c) effect was described in a paper presented at the last cold fusion conference in Marseilles (3).

In what follows I focus on the Oriani solid effect. It consists of demonstrating emission of charged nuclear particles from the nickel cathode during and after the electrolysis. The particles were recorded in a detector placed in air, 1.5 cm below the nickel foil. I have no doubt that some kind of nuclear activity is triggered in the Oriani cell during the electrolysis.

In my opinion, Oriani effects should not be labeled "cold fusion", as defined in 1989 (4); neither palladium nor heavy water are used in the setup. What happens in the cell cannot be a fusion of two deuterium nuclei. This would be highly improbable due to repulsion of positive nuclei and due to the quasi-absence of deuterium in ordinary water. If it were up to me I would replace the term "cold fusion" by the term "anomalous nuclear activity" and would invent separate names for different effects, such as: generation of neutrons, excess heat, production of tritium, accumulation of helium, transmutation of isotopes, etc., etc. But, being realistic, I know that the term "cold fusion" will be used (inappropriately) as an umbrella for a large number of effects (that may or may not be related). That is how I am going to use this term.

The figure below is a simplified drawing of the Oriani cell. I plan to use such cell in my own experiment at home. Note that the nickel foil is squeezed between the two rubber O-rings (dark circles). The two vertical tubes (inner diameter 1.5 cm), into which the O-rings are inserted, are called "flanged joints." The two aluminum plates that press the joints toward each other (with screws) are not shown. The upper tube is partially filled with the electrolyte into which a

platinum wire is inserted. The lower part of the wire, a pancake-like spiral (diameter of about 1.3 cm), is used as an anode.

Chemicals needed (NaOH and Li_2SO_4), are likely to be available in a typical school laboratory. Chemicals can also be purchased, for example from Aldrich Chemical Company, Inc. The estimated cost of major components is:

Two flanged joints, $20
Six pure nickel foils, 0.125 mm, 15 by 15 cm each (enough for 30 cells) $150
Lithium sulfate, 99% pure, 100 grams (enough for hundreds of experiments), $21
Sodium hydroxide, 1 kg, (enought for hundreds of experiments), $26
Platinum wire (0.25 mm diameter and 25 cm long), $30

All these components can be purchased, for example, from Aldrich. The most expensive components, the power supply and an optical microscope, are likely to be available in a typical school laboratory. The microscope magnifications of 40 and 200 are sutable. The clamps holding the joints togrther can be quite expensive, for example, $150, if custom-made in a commercial machine shop. But a pair of large washers, with three matching holes along perimeters, can also be used to push the joints toward each other with a set of three screws. The inner openings of washers should be slightly larger than outer diameters of tubes. A set of two brass wall flanges, from Lido Rail Systems (costing $6.50 in Home Depo), is an ideal clamp for tubes whose outer diameters are between 0.8 and 1.0 inches. This is only an example; any set of rigid curtain rod holders, with holes, would be suitable, provided it matches the tube diameters.

The actual vertical cell used by Oriani is only slightly more complicated than that shown in Figure 1; it has wires to suspend additional detectors, some to be kept in the liquid and others to be kept above the liquid. These additional detectors are used to study the (a) and (b) effects. I plan to replicate only the (c) effect. An experiment for teachers and students should be as simple as possible.

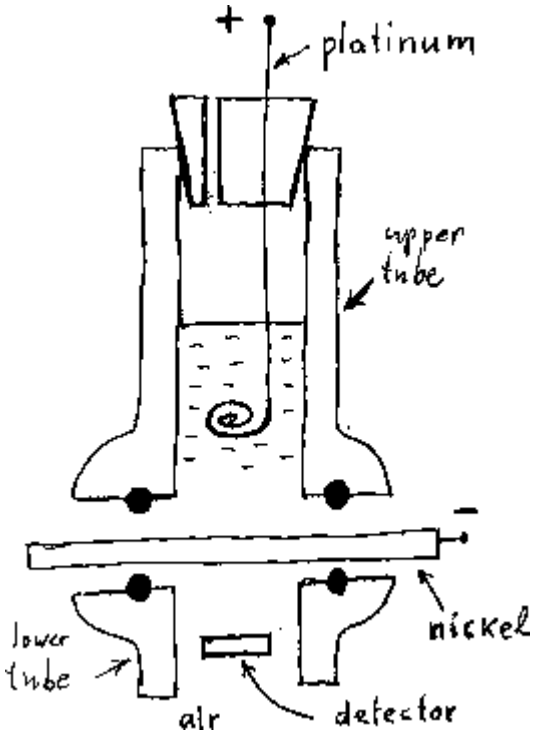

Figure 1

Let me now describe one of the experiments performed in Oriani's lab. We inserted a new nickel plate and prepared fresh electrolyte (2.36 grams of Li_2SO_4 per 100 cc of the ordinary water). The surface of the nickel, to face the

electrolyte, was scratched with a sharp knife. Oriani said “this can not hurt, it might help.” Then the cell was assembled, the electrolyte was introduced into it (with a pipette) and the current was turned on for 72 hours. During the first 24 hours the current was 0.20 A, during the next 24 hours it was 0.27 A, and during the last 24 hours it was 0.33. Oriani said: “I do not know which current is the best so I use several different currents.” A large number of tracks of nuclear particles was recorded by the detector situated in air below the cathode. The distance between the detector and the cathode was 1.5 cm.

After three days the electrolyte was removed and the cell was dismounted. The nickel cathode was at once sandwiched between two CR-39 detectors (see the appendix below) for 26.5 hours. Once again, a large number of nuclear particle tracks was recorded. Figure 2 is a typical photo of tracks seen unser the microscope. The surface area shown in Figure 2 is very small; most of the areas of that size, for control chip measuring the background, display zero or one tracks. Encountering three tracks on such small area is very rare. A typical background for our detectors is 10 tracks per square centimeter (fluctating between 0 and 30).

72 hours of exposure during the electrolysis

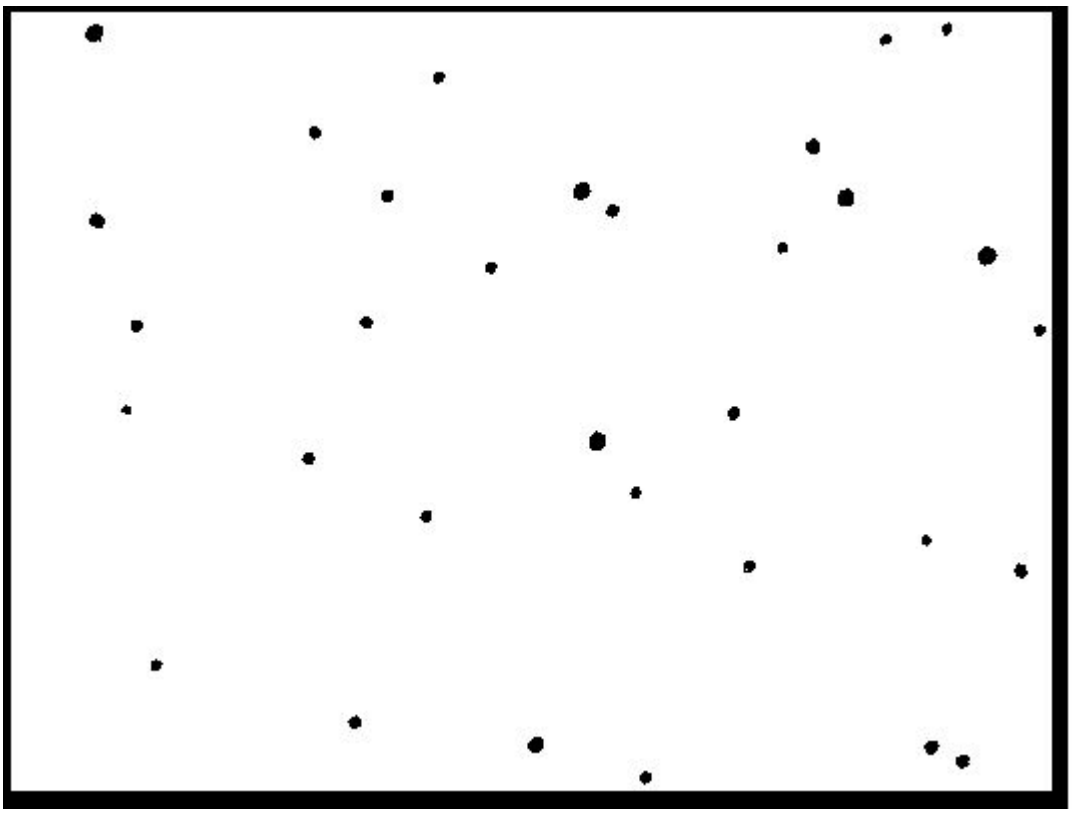

Figure 2

The area of the detector used during the electrolysis was about 0.6 cm^2. The number of tracks recorded on it was found to be 1816. This translates into the track density of 3026 per square centimeter and to the recording rate of 42 counts per hour per square centimeter. That is about 300 times higher than our typical background. In other words, what is shown in Figure 2 is certainly not the residual tracks due to radon and cosmic rays. Was the rate of emission constant during the electrolysis? An experiment in which the CR-39 detector is going to be replaced by an electronic (surface barrier) detector is in preparation. After that experiment Oriani should know the answer to this question. He will also measure the energy spectrum of unexpected particles emitted by nickel during the electrolysis.

Tracks recorded after the end of electrolysis.
The cathode was removed from the cell and immediately sandwiched between two fresh CR-39 detectors for 26.5 hours. After that the detectors were etched and tracks were counted on all four surfaces. Each surface had an area of 1.2 cm^2. The results are shwn below. The terms “front” and “rear” are used by Oriani to identify two surfaces of a single chip.

Front is the side facing the cathode and rear is the opposite side. The cathode also has two distinct surfaces, one called "wet" (because during the electrolysis it was in contact with the electrolyte) and another called "dry" (because during the electrolysis it was in contact with the outside air). The detector facing the "wet" cathode recorded 951 tracks in "front," and 122 in "rear." These numbers are significantely different than what was detected on the "dry" side of the cathode. The detector placed on that side recorded 132 tracks in "front" and 7 in "rear." Note that 951 tracks translates into 30 tracks per hour per square centimeter.

The second test for the emission of particles (with a fresh pair of CR-39 chips) started 27 hours after the end of electrolysis and lasted 70 hours. During this test the detector facing the "wet" cathode recorded 1529 tracks in "front" and 373 in "rear." These numbers are significantely different from what was detected on the "dry" side of the cathode. The detector placed on that side recorded 80 tracks in "front" and 22 in "rear." Note that 1529 tracks translates into 18 tracks per hour per square centimeter. Keep in mind that the geometry of counting during the electrolysis (detector 1.5 cm below the nickel cathode) was very different from the geometry of counting after the electrolysis (when each detector was in contact with the nickel foil).

Considering a possibility that our nickel foils (nominally 99.99% pure before the electrolysis) might contain traces of naturally radioactive materials, such as uranium or thorium, we performed an additional experiment. A fresh piece of nickel, cut from the same large piece as the cathode, was sandwiched between a pair of CR-39 detectors, also for 26.5 hours. After that exposure the detectors were etched and examined. All four surfaces had nothing but the background. This rules out a possibility that particles, detected during the electrolysis, or after the electrolysis, were due to a contamination.

Was the emission of anomalous nuclear particles after the electrolysis uniform during the 26.5 hours of exposure or were most of the particles emitted quickly after the current was turned off? Additional data are needed to answer this question. I will append more information, about our investigations of the Oriani solid effect, as more data become available. Information from the electronic detector is likely to shed much more light on the nature of the unexpected nuclear effect triggered by chemical processes in the cell. For the time being we think that tracks recorded by CR-39 detectors are due to alpha particles and protons. This would be consistent with two distinct groups of track diameters, large and small. Protons and alpha particles have already been observed, in very different cold fusion experiments, by other investigators (5,6). My personal expectation, based also on the experiment described in unit #184, is that some kind of radioactivity, with a long half-life, is somehow induced in nickel. But the only things we know for sure, so far, is that: (a) charged nuclear particles were detected in the air below the nickel cathode during the electrolysis, and, (b) the cathode was emitting such particles after the current is turned off. I will stay away from trying to explain these strange phenomena.

Let me end this unit by inviting other people to replicate our observations. According to Oriani, about 60% of attempts to observe the effect (seeing track densities high above the background) were successful. This is based on about thirty attempts. My personal experience, in Richard's lab, was two undeniable successes in two attempts. Some people say that an experiment should be 100% reproducible before it can be taken seriously. I disagree; even 10% is sufficient, provided a qualified person, such as Jones, Fleischmann or Oriani, is reporting something new and unexpected. To be taken seriously does not mean to be accepted as real; it means to study a phenomenon intensively until it becomes 100% reproducible, at least approximately. A qualified researcher should never be denied access to a scientific journal without an honest peer review process , Ridiculing scientists whose reports can not always be confirmed does not promote our understanding of nature.

The task of those of us who will start studying the Oriani effects would be to identify a factor (or factors) responsible for the lack of total reproducibility. Is it humidity? Is it pressure? Is it time of the day? Is it the number of solar flares? Is it the noise level? Is it proximity of a magnet? Is it the day of the week? Is it wishful thinking? Is it dust? Is it experimenter bias? If the effect is real, and if a large number of people are studying it, then, sooner or later, the experimental conditions needed for the 100% reproducibility will be identified. It is so unfortunate that Oriani's attempts to publish a paper describing similar results was recently rejected by several physics journals. How can science develop if qualified researchers are not allowed to make their findings known? I hope that such abnormal discrimination (of a field of research) will soon be condemned by those responsible for scientific research. When will the DOE appointed investigators publish their report?

P.S.(11/23/04)
Oriani wrote to me today that the vapor effect (b) seems to be more reproducible than the solid effect (c), described in this unit. Should I write a separate unit devoted to the vapor effect? I might, when time becomes available. For the time being I want to stop writing, and start working. I hope to observed mysterious nuclear particles, below the Oriani cell, in my laboratory.

P.S.(11/24/04)
Oriani also discovered tracks of nuclear particles on detectors placed in air ouside the glass tube, during the electrolysis. Referring to these recent findings he wrote to me: "I have found greater reproducibility with chips in the vapor than with chips stuck to the outside surface of the glass of the cell." Then he suggested that I focus on the vapor effect rather on the solid effect. I resisted; in the reply I wrote: "Since you are not categorically against focusing on the solid effect I will focus on it, as originally intended. The advantages are: simplicity (no need for the spot-welded hooks, no need for the 'roof plate' above the liquid, no need for the anicondensational heating of the vapor) and a possibility of replacing the CR-39 chip with an electronic detector. I do plan on using the electronic detector, after confirming your experiment once again at my own place. Your vapor effect deserves its own unit and I will try to compose it later."
The photo of Richard Oriani, taken by me, is shown below.

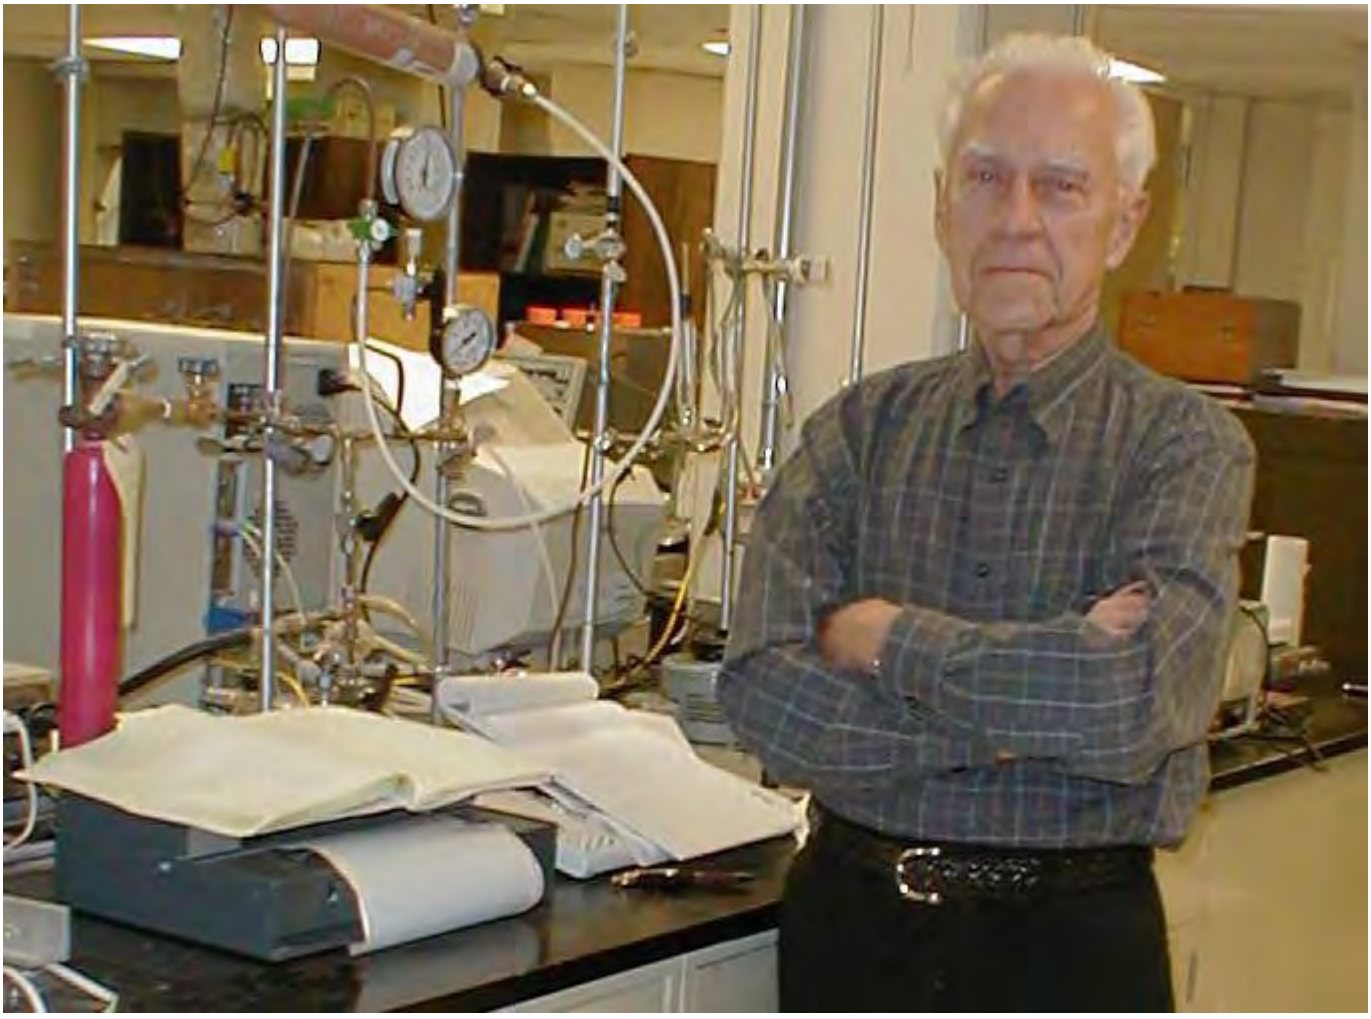

Figure 3

The next picture shows Oriani vertical cell during our experiment. Note the hexagonal plates squeezing the two O rings toward each other; these plates were not shown in Figure 1. The electrolyte in the upper tube (white) is full of escaping bubbles. The space above the electrolyte is heated from the power supply on the left. This prevents condensation of vapors on CR-39 pieces used to study the Oriani vapor effect. The power supply on the right is used to control the current flowing through the cell.

Figure 4

The last picture below was taken at the recent cold fusion conference (November 2004) in France. It shows two theoretically inclined cold fusion scientists (T. Chubb on the left, and J. Fisher) discussing something. Their attempts to make sense out of cold fusion phenomena are very different. They are not alone; I know names of several other scientists advancing their own theoretical interpretations. Note that most cold fusion researchers are old. Young people are usually told to stay away from that field of research. What a shame! They should be actively involved in trying to either validate or invalidate experimental data and emerging theories. In my opinion cold fusion is an ideal ground for practicing scientific methodologies because experiments are relatively simple and relatively inexpensive. Who is responsible for the unhealthy social environement surrounding cold fusion? Those who still think that all cold fusion phenomena are pseudoscientific. Will the situation be corrected after the report of the DOE appointed panel is published? I hope so.

Figure 5

P.S.(11/25/04)
A friend who read this unit asked about the energy balance. My answer was that “no measurable amount of excess heat would be expected on the basis of the number of observed tracks, even if each track was associated with 2000 MeV of heat. This number is eleven times larger that the energy from a single fission of uranium nucleus. The way to demonstrate this is simple. Assuming the average voltage and current are 6 V and 0.3 A, respectively, the input power is 6*0.3=1.8 W. The power associated with the 1816 tracks, recorded in 72 hours, would be (under the above assumption) 2000 MeV * 1816 /72 = 50440 MeV/hour. This translates into $3.11*10^{-14}$ W. Assuming that tracks detected by the CR-39 located 1.5 cm below the cathode represent only 5 % of tracks emitted in all directions the output power becomes $6.2*10^{-13}$ W. This is nearly nothing in comparison with the input power of 1.8 W. In other words, the number of reaction products is too small to produce a measurable amount of excess heat during the electrolysis. This is consistent with earlier observations of other researchers (5,6). The assumption of 2000 MeV of energy per track was deliberately exaggerated in favor of excess heat. The real energy per track is likely to of the order of several MeV.

P.S.(11/25/04)
Would a person who is convince that "cold fusion is nonsense" read my paper? I do not think so. Like many others, including people I know personally, s/he probably thinks that it is a waste of time to read research reports in the area of cold fusion. But suppose s/he was forced to come to our conference. Would s/he use earplugs to avoid listening to what Oriani, or other active scientists, had to say about recent findings? Probably not. And would s/he accept an invitation to assist in a real experiment, like the one I am going to perform next week? That would be an indication that s/he is ready to change previousely held vews in face of new evidence. Why is such step so difficult for many people?

Appendix: The CR-39 detectors
. . . . . .
Most scientists are aware of the role played by track detectors in nuclear physics. A large number of discoveries were made by using first track detectors: cloud chambers and nuclear emulsions. CR-39 detectors, like nuclear emulsions, can be developed to show tracks made by protons and alpha particles. They are made from the same matrial (labeled CR-39) as plastic eye glasses. The process of development consists of etching the exposed material in a hot solution of NaOH (6.5 N at 65 degrees C) for several hours. Our method of detection of the unexpected particles is essentially the same as that used to detect alpha particles from radon, for example in air or water. Fortunally, the CR-39 material is

commercially available (7) in the form of flat sheets or chips, typically ~1 mm thick. An alpha particle, for example from radon in a basement, intercepted by a CR-39 chip, creates a tiny track of damaged chemical bonds that can be made visible by etching (7). Tracks can then be observed by using a common microscope (8). An extensive review of track detectors has been published recently (9)

189) Summary of my CF research

Ludwik Kowalski (November 26, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

My cold fusion investigations, reflected on these webpages, started during the sabbatical year of 2002/2003. It was essentially a literature research project on the topic that I had believed to be pseudoscientific for about ten years. After changing that attitude, on the basis of what I read, I started looking for a simple cold fusion experiment that could be performed by teachers like myself, and by their students.

The first attempt in that direction -- working for one week with H. Fox and A. Jin in Salt Lake City -- was a failure. What we discovered was a poor interpretation of experimental results from an earlier investigation (see units #44 and #45).

The second attempt was a visit to Provo, also in Utah, to talk with S. Jones at Brigham Young University. That was after I met Jones at the 10th cold fusion conference (August 2003), and after I heard his report (see unit #113). The visit led to my investigation of a Ti foil impregnated with deuterium. The sample was sent to me by Jones; it was made by keeping the titanium foil in deuterium gas at high temperature and pressure. We wanted to see if the 3 MeV protons, discovered by Jones, can also be observed by using a CR-39 detector. That approach would be more suitable for a student-oriented project than using sophisticated electronic detectors.

The result of my study confirmed Jones' observations but they were not as spectacular as the results from the investigation of another foil (see the description starting in next paragraph). The number of tracks counted on the face of the CR-39 detector that was applied to Jones' foil (for 55 days) turned out to be 225 The opposite side of the same CR-39 detector (exposed to air) was used to count tracks due to our background. That number of background tracks turned out to be 132. The size of the CR-39 detector was one square inch.

The third attempt to observe "a nuclear signature" in cold fusion was my collaboration with D. Letts, as described in units #182, #183 and #184, at this website. Once again, I used CR-39 detectors (see item #185 on this website). Three palladium cathodes (used in electrochemical cells) were sent to me: Pd613, Pd616 and Pd615. The first one was from a cell that produced a very high amount of excess heat, the second was from the cell that produced significantly less excess heat and the third was from the cell that failed to produced excess heat. Without knowing anything about thermal histories of these cathodes I found a huge number of tracks due to Pd613, much less tracks due to Pd616 and only background tracks due to Pd615.

I was subsequently informed all three cathodes were cut from the same Pd foil, and that the electrolyte used in all three cells was prepared at the same time. But a tiny amount of the so-called "sauce #1" was later added to the cell containing the Pd613 cathode. The X-ray fluorescent analysis of the sauce revealed presence of uranium. (Dennis Lets wrote: "The additive I used on cathode #613 was Cravens sauce #1. This is the same additive titled "Pixie Dust" on the analysis done by Scott Little showing small amounts of Uranium.") Be aware that no sauce #1 was added to the electrolytes used in the other two cells. I asked Dennis to send me a sample of the souse. He did and I dried it under a lamp. Then a CR-39 detector was applied to the thick dark spot of what was left after the liquid has evaporated. After three weeks that detector revealed a huge number of tracks. A test for the contamination of the Pd613 cathode itself consisted of its reexamination after three weeks. The number of tracks observed, in the cluster of highest density, was essentially the same as three weeks earlier. In other words, an attempt to rule out the contamination failed. (I would be able to say that there were no uranium contamination if the track density decreased significantly in three weeks. But this did not happen.)

Facing this situation I decided to ignore the Pd613 data, for the time being, and use the data from the Pd616 and Pd615 cathodes. No sauce #1 was added to the electrolyte when these two cathodes were used in the excess heat experiments. The Pd615 provided an ideal control sample; it was treated in exactly the same way as Pd616 but failed to generate excess heat. A very large difference between the track densities from the Pd616 and Pd615 was a strong indication that an unexpected nuclear effect is indeed associated with generation of heat in Letts experiments.

I think that excess heat demonstartions, designed to convince that something highly unusual (cold fusion) is taking place, should always be accompanied by attempts to display nuclear signatures. That what I wrote to Letts when I asked him for a chance to examine a cathode. After all, there are many ways to get more heat out than heat in, especially at the power level below one watt. A complete examination of all chemical processes taking place in a setup (to convince that the excess heat is not chemical) is much more demanding that using a nuclear detector of some kind. Cold fusion effects, if they are nuclear, must generate nuclear reaction products, either radiaoactive or stable. Nobody argues with this expectation. Scott Little, from Letts' team, wrote to me that they will start using CR-39 detectors. I expect them to apply CR-39 to each cathode as soon as the electrolysis is finished (not much later, as I did). Will they observe a decrease in track densities after subsequent reexaminations of a removed cathode, for example, once every two week? That remains to be seen. The team plans on announcing the results of their recent findings at the end of this year.

Let me now return to the cathode #613. The CR-39 detector applied to the cathode for the second time, three weeks after the end of the first exposure, showed no significant decrease in the track density. I consider this to be a failure to rule out the effect of uranium contamination. But this does not prove that contamination was responsible for most of the observed tracks. It is not apriori evedent that a two or three drops of souce #1, in which concentration of uranium was very low, could produce (after being diluted in the electrolyte) as many tracks as was actually observed. A good way to test for the uranium contamination would be to replace the CR-39 detector with an electronic detector able to identify particles (are they alpha particles or not?) and able to determine their energies (are the uranium-chain peaks observed or not?) Let me now focus on two experimental facts that are not consistent with the idea of contamination.

(a) The electrolytic cell had a nearly axial symmetry. It was a round beaker with a small cathode (about one square centimeter) suspended at the center. The anode was a spiral platinum wire surrounding the cathode. The radius of the spiral, as far as I could determined from a photograph emailed to me, was about three centimeters. The only asymmetry was introduced by the laser beam; one side of the cathode was exposed to that low energy beam during the excess heat experiment while the other side was not. The laser beam was expected to trigger the mysterious excess heat phenomenon.

(b) If the tracks from particles emerging from the Pd613 cathode were due to uranium dissolved in the electrolyte then the track density would be essentially the same on both sides of the Pd613. In reality, however, the number of tracks on the CR-39 detector applied to one side of the cathode was very much higher than on the detector applied to the other side of the cathode. Furthermore, the track density (on the side of the cathode that was more active than the other) was very nonuniform. I suspect that the observed cluster (of maximum track concentration) coincides with the spot at which the laser beam was intercepted by the cathode. It would be interesting to know if that suspicion is confirmed by Letts' team. On the other hand, I am aware that, at least in principle, uranium (from the uniformly dissolved sauce) could prefer to migrate to one particular spot on the surface of the cathode.

My fourth attempt to find a student-oriented experiment showing that a nuclear process can be caused by a chemical process was the most successful. It was described in the unit#188 on this website. The experiment is simple and relatively inexpensive; the total cost of materials to build a cell should not exceed $200. I will have more to say about this experiment after trying to replicate it in our laboratory at Montclair State University. A task of trying to prove, or disprove, a controversial claim made by a reputable scientist can be turned into an educational project. What can be a better way to expose students to the excitement of scientific research? That is why I am trying to convince teachers that Oriani's experiments are worth replicating. Please read my unit #188 and try to replicate the experiment. Then share your results. I would be happy to write about your findings in another unit, perhaps before the end of the current school year.

190) A better name for “cold fusion?”

Ludwik Kowalski (November 26, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

Naming something is an important component (not the most important) of promoting it. This is probably a well known fact among advertisers and propagandists. The label “cold fusion,” as often stated, is not appropriate even as a generic term for a broad group of phenomena. Other names have recently been suggested, for example: LENR (low energy nuclear reactions); CANR (chemically assisted nuclear reactions); and CMNS (condense matter nuclear science). Before suggesting another name let me say why the existing names are not ideal, in my opinion.

(a) The name cold fusion (CF); would be appropriate for a reaction in which two atomic nuclei fuse into one at not-too-high temperatures. (Temperatures can be expressed in units of energy and by “not-too-high” I mean one eV or less. Only stellar temperatures are high enough to make fusion of atomic nuclei observable.) Fusion of two isolated atomic nuclei is highly improbable at ordinary temperatures. That theoretical conclusion (the tunneling effect) is not disputed by cold fusion scientists. But they often argue that, in condensed matter, fusing nuclei are not isolated. I will return to this in (c) below.

(b) The LENR and CANR names are not ideal because they contain the word “reaction. ” That word also implies interactions between two particles. The particles are atoms or molecules, as in chemistry, or atomic nuclei, as in nuclear science. The name LENR, by the way, has already been used for something else. In most nuclear textbooks low energy nuclear reactions are defined as reactions at which the kinetic energies of colliding nuclei do not exceed several tens of MeV. Using the same name for two different things can be confusing.

(c) The most recently introduced name, CMNS, is not ideal because the term “condensed matter” excludes gases. One of the effects discovered by Oriani (see unit #188), does seem to be taking place in a vapor. Likewise, the sonoluminescent nuclear anomaly seems to be taking place in bubbles.

The name I would like to suggest is CANA -- “chemically assisted nuclear anomaly” or “chemically assisted nuclear activity,” depending on how much is understood. The name is broad enough to include all experimentally observed (anomalous nuclear) effects; it has not been used to describe something else, and it is easy to pronounce, at least in languages with which I am familiar.

Of course, each CANA phenomenon should have its own distinctive name. Generation of excess heat, associated with an anomalous nuclear activity, for example, can be named “Pons effect;” it was first announced by Pons and Fleischmann. Emission of neutrons and protons, discovered by Jones et al., can be named “Jones effect” and phenomena described in the unit #188 can be called “Oriani effects.” Associating new effects with names of those who discovered them has been common in physical sciences. Not all effects, however, are named after their discoverers. The photoelectric effect, for example, does not reflect the name of the scientist who was the first to publish its discovery, or its interpretation. Such approach would likely be appropriate for situations in which effects have been discovered, more or less simultaneously, by several researchers.

191) Polyneutron model of John Fisher

Ludwik Kowalski (November 25, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

1) Introduction:
During my visit to Minneapolis (see the unit #188) I asked Dr. Oriani about his motivation for placing CR-39 detectors into the vapor. Most cold fusion researchers think that the unexplained nuclear phenomena (inappropriately referred to as cold fusion) occur in metals. His answer surprised me. He said "I was guided by a theory of John Fisher." Up to that time I thought that not a single cold fusion phenomenon was predicted theoretically, all of them were discovered experimentally first. Who is Dr. Fisher? He was trained as a mechanical engineer, and as a mathematician. His early professional life was spent in a General Electric research center at Schenectady, NY. A photo of that retired theoretical scientist is shown in the unit #188.

John conceived polyneutrons, more than ten years ago, as "particles" responsible for all cold fusion phenomena. Do these theoretical particles really exist? That is an open question. This situation reminded me the history of neutrinos that were also invented theoretically by Pauli. I talked with John briefly during the tenth cold fusion conference and much longer during the last conference in Marseilles. In a private conversation he told me that many cold fusion people do not take his theory seriously. "Their attitude toward me is similar to the attitude of the official scientific establishment toward all of us." That was another revelation; up to that point I was under the impression that cold fusion people do not criticize each other. I thought that they probably support each other in fighting with the common enemy -- the official scientific establishment. That establishment consists of managers of government laboratories, directors of financial support agencies, editors of journals and numerous self-appointed guardians of our current paradigm.

2) Neutrium, the first element:
The first assumption of John's theory is the existence, in our environment, of a not-yet-recognized element number zero. Atoms of that element contain neither electrons nor protons; they are aggregates of neutrons bound by strong nuclear forces. He visualizes them as electrically neutral droplets of condensed nuclear matter. They are neutral atomic nuclei of an element that I would like to be named. All known elements have names and symbols. Symbols are needed to write nuclear reactions. Symbols of elements consist of one or two letters; the first letter is always capital, as in Zn, O, or Fe.

In this essay I will refer to the element # zero as Neutrium and I will use the symbol Nt to represent it. The name neutrium was suggested to me by John Fisher. He refers to isotopes of that element, such as ^{4}Nt, ^{5}Nt, ^{6}Nt, ^{7}Nt, etc., as polyneutrons. The symbol ^{A}Nt is used for a polyneutron containing A neutrons. Unlike ordinary elements, neutrium was not discovered experimentally, it was invented by John to explain anomalies of the so-called "cold fusion." This reminds us of a neutrino, a particle invented in 1930s to make sense of the apparent anomaly in beta decay.

John Fisher thinks that polyneutrons can contain more than 1000 neutrons kept together by strong nuclear forces. A neutron star, on the other hand, is not a gigantic polyneutron because its neutrons are kept together by gravitational forces. John is aware that polyneutrons of size two or three can not exist. He believes, on the basis of reference (1), that the smallest possible polyneutron consists of four neutrons. In trying to explain stability of nuclear droplets made from neutrons, and knowing that two neutrons "do not stick," John brings an analogy with liquid helium. Two or three atoms of helium do not make molecules but liquid helium exists. I would like to know what other people, more knowledgeable that I am, think about that analogy.

In answering one of my questions John Fisher said that "polyneutrons arise in nature as decay products of exceedingly rare precoursor nuclei." This, however, does not necessarily mean that one has to cover a lot of territory to encounter one or two of them. Suppose there is only one precursor nucleus per quintillion (10^{18}) molecules of air. That would certainly make them "exceedingly rare." But, even at such level of concentration, every cubic inch of air would still contain nearly 1000 of them to produce polyneutrons when they decay. The main point here is that "atoms" of neutrium are usually available to produce various effects, provided favorable conditions are encountered. What is meant by favorable conditions is explained below.

3) Unusual nuclear reactions:
Unlike electrically charged projectiles, polyneutrons are not repelled by ordinary atomic nuclei; nuclear reactions induced by them are not inhibited by repulsive coulomb forces. All cold fusion abnormalities, according to Fisher, are due to nuclear reactions that involve polyneutrons.. Another alternative is to think that cold fusion phenomena are due to ordinary neutrons. John rejects this alternative because far too few neutrons are seen in cold fusion experiments. He also rejects models postulating that coulomb barriers can somehow be lowered. In other words, Fisher thinks that the term "cold fusion," as defined in 1989, is totally inappropriate. Taking coulomb barrier arguments very seriously he does not believe that two deuterium nuclei, for example, can fuse at ordinary temperatures.

A nuclear reaction can be either exothermic or endothermic, depending on its Q value. This topic is reviewed in the Appendix 1. Here is an example of a nuclear reaction involving two polyneutrons:

$$^{A}Nt + {}^{18}O \dashrightarrow {}^{16}O + {}^{(A+2)}Nt \text{.....(1)}$$

The letter A is used to indicate the atomic mass number (number of neutrons) of the polyneutron on the left side of the equation. The polyneutron on the right side contains two more neutrons than the polyneutron on the left side. This particular reaction turns ^{18}O into a common isotope of oxygen, ^{16}O. Another possible polyneutron reaction, according to Fisher, is:

$$^{A}Nt + {}^{2}H + \dashrightarrow {}^{3}H + {}^{(A-1)}Nt \text{..... (2)}$$

Here the mass of the polyneutron decreases by one unit while the mass of the hydrogen increases. One can imagine many nuclear reactions of that kind. But not all of them can occur spontaneously. Most are possible only with an accelerator. Whether or not a reaction can take place spontaneously, at an ordinary temperature, depends on its Q value. The well known way of calculating Q values of nuclear reactions is reviewed in the Appendix 1. Only exothermic reactions, those whose Q values are positive, can happen spontaneously. That is why the ability to calculate Q is so important. To calculate the Q value of a reaction involving isotopes of neutrium, such as:

$$^{A}Nt + {}^{18}O \dashrightarrow {}^{16}O + {}^{B}Nt + {}^{C}Nt \text{.....(3)}$$

one must know exact masses, or mass excesses, of all participants. The concept of the mass excess is reviewed in the Appendix 1. Note that in this reaction ^{18}O is transmuted to ^{16}O and a polyneutron of size A is split into two smaller polyneutrons. Naturally, the sum B+C must be equal to A+2. Mass excesses of ordinary nuclei are well known; they can be found in many nuclear physics textbooks (3). But how can the mass excess of a polyneutron, with atomic number A be determined? According to Fisher that quantity, , the mass excess $\Delta(^{A}Nt)$, is given by:

$$\Delta(^{A}Nt) = k*A$$

where A is the number of neutrons in the polyneutron and k is an unknown constant. This formula, based on the liquid drop model, is only an approximation. The term associated with the surface energy is ignored; only the volume energy term is retained. To impose a limit on the numerical value of k John notes that from the beginning of his theory he "had the idea that chain reactions were involved and that atoms such as ^{7}Li, ^{18}O, and ^{2}H might serve as fuels. When Oriani and I later observed a shower of about 150,000 alpha particles in the oxygen/hydrogen vapor over an active electrolysis cell, I assumed that oxygen could support a chain reaction, which requires that the Q value of reaction (1) must be positive." The initial statement that the Q of the reaction (1) is positive is essential in Fisher's theory. Should we say that this statement is based on experimental facts or should we say that it is a very clever arbitrary, assumption? I want to know what a philosopher of science would say about this.

If we accept that the Q of the reaction (1) is larger than zero then, as show in the Appendix 2, k must be smaller than 1.98 MeV/u. Note that the unit of $\Delta(^{A}Nt)$ is MeV while the unit of A is u (atomic mass unit). That is why, the unit of k is MeV/u.

"The other limit imposed on k i based on another experimental observation. Spontaneous generation of tritium from deuterium has been reported by cold fusion researches." Assuming that this transmutation is due to the reaction (2), Fisher states that the Q of this reaction must also be positive. This, in turn, as explained in the Appendix 2, means that k must be larger than 1.82 MeV/u. These two limits narrow the range of values of k to $1.82 < k < 1.98$. The middle of that narrow region is 1.90 MeV/u. On that basis John assumes that k is equal to 1.90, plus or minus about 4.5%. By knowing k he is able to calculate Q values of many reactions involving polyneutrons, as illustrated in the Appendix 2.

4) The chain reactions process:

The ^{18}O isotope exists in air, water and mineral surrounding us; about 0.2% of all oxygen on earth is ^{18}O. Reaction (1) is a growth reaction. Colliding with successively encountered ^{18}O nuclei a small polyneutron can grow and grow. Reaction (3) is a splitting reaction. Here a single polyneutron disappears and two smaller polyneutrons appear. The combination of reaction (1) and reaction (3) amounts to a chain process. Under favorable conditions (to be explained later) a polyneutron grows through frequent encounters with ^{18}O. When it become large enough (typically when A becomes several hundred) the reaction (3) occurs and the large polyneutron splits into two smaller polyneutrons.

These two also start growing through the reaction (1) till they split through the reaction (3). After that we have four polyneutrons. Subsequent repetitions of reactions (1) and (3) bring the number of neutrons to 8, 16, 32, etc. Both reactions (growing and splitting) are exothermic and nuclear energy is released in this chain process. John compared it to a chain reaction in a typical nuclear power plant. The ^{18}O, according to Fisher, is not the only fuel able to support a chain process. In a recent message he illustrated this with an interesting example:

$$^{A}Nt + {}^{7}Li \dashrightarrow + {}^{4}He + {}^{1}H + {}^{(A+2)}Nt \quad \text{.....(1')}$$

where a stable isotope ^{7}Li, interacting with ^{A}Nt, brakes into ^{4}He and ^{1}H. This is accompanied by the growth of the polyneutron, as in reaction (1). The Q value of this exothermic reaction is 1.39 MeV. A sequence of many (1') reactions, followed by the reaction (3), is a single step of a chain process. The fuel in this energy generating process is ^{7}Li. Is it conceivable that accumulation of helium, reported by several cold fusion researchers is due to the reaction (1')? Answering this question John wrote: "Yes some helium comes from the ^{7}Li reaction. But some comes too from the decay of poisons and some from the decay of polyneutrons. So depending on circumstances the ratio of helium to energy can vary quite a lot from experiment to experiment." The meaning of the term "poison," in this context, is explained in the next section.

5) Poisoning processes:

Suppose that the above described chain process develops spontaneously somewhere in the atmosphere, or in the ocean. Then we would have a tremendous nuclear explosion on a planetary scale. Fortunately for us, this can not happen. Why

not? For the same reason for which a chain reaction in a power plant can not go on indefinitely, because the chain generates reaction products that act as poisons. In the context of a power plant "poisons" are fission products; they trap neutrons that would otherwise be available for the chain reaction. In the so-called "cold fusion" context poisons are structures composed of a polyneutron and a ^{16}O nucleus that are stuck together like tiny drops of oil and water, each retaining its identity, but held together by a reduction of surface energy over the area of contact. Poisons can form in reactions such as:

$$^{A}Nt + {}^{18}O \text{ --> } {}^{16}O\ {}^{B}Nt + {}^{C}Nt \text{ . . . . . } (B + C = A + 2) \text{.....(4)}$$

Which is just like reaction (3) except that one of the product neutrium atoms sticks to the ^{16}O. The $^{16}O\ {}^{B}Nt$ composite nuclei are massive oxygen isotopes and they are the poisons. They absorb polyneutrons that would otherwise be available for the chain reaction and remove them from the system:

$$^{A}Nt + {}^{16}O\ {}^{B}Nt \text{ --> } {}^{16}O^{(A+B)}Nt. \text{ .....(5)}$$

The ^{A}Nt and ^{B}Nt nuclei, merged into a single droplet $^{(A+B)}Nt$, are still stuck to the ^{16}O. The reaction is exothermic and the released energy consist of gamma rays.

These poisons rapidly accumulate and by capturing polyneutrons they extinguish chain reactions at the very early stages of development. They prevent catastrophic explosions in our environment. Note that only exothermic reactions are allowed to take place. The symbol $^{16}O^{A}Nt$ refers to what John calls a composite nucleus. It is an ordinary nucleus, in this case ^{16}O, that is stuck to a polyneutron in the same way that a drop of water and a drop of oil can be stuck together by a reduction of surface energy over the area of contact. If A=300, for example, then the the composite nucleus (on the right side) can be said to be a superheavy isotope of oxygen; its atomic mass number is 316. It is a nuclear molecule. After trapping another polyneutron, that merges with the polyneutron already there, the atomic mass of the composite may become 800, or 1300, depending on the size of the captured aggregate. Note that the composite nucleus is a positively charged particle; it is repelled by ordinary nuclei, such as ^{18}O, and also by other composite nuclei. Only polyneutrons are neutral.

As indicated above, composite nuclei are poisons; they soak up polyneutrons that would have otherwise been available to the chain reaction process. Poison-creating reactions (capturing more and more polyneutrons) are exothermic. As composites increase in number, via reaction (4) they soak up polyneutrons more and more rapidly. That is why chain reaction processes extinguish themselves, sooner or later.

In comparing chain reactions based on fission of uranium with chain processes based on reactions (1) and (3) John said that what takes several months in the first case (accumulation of fission products) takes only several milliseconds in the second case (accumulation and growth of composite nuclei). This, he said, is due to very large cross sections (high probabilities) of reactions involving polyneutrons.

6) Favorable conditions:

To sustain a chain reaction process in a small region of space, as described above, the fuel must be supplied and poisons must be removed. That is what constitutes favorable conditions, according to Fisher. He thinks that rapid stirring to remove poisons might be a mechanism necessary to sustain generation of nuclear energy through the chain process. This might happen, for example in the bubbling region in an electrolytic cell, near a water fall, in a geyser, along a mountain stream, etc.,. Favorable conditions can also be created when a flow of deuterium ions is imposed on a material structure, as in Iwamura experiments. More favorable conditions allow to sustain chain reaction at a high average rate. A useful cold fusion reactor would require a setup in which favorable conditions are sustained in sufficiently large regions of space.

At one point an analogy was introduced to further clarify the meaning of "favorable conditions." Consider a glowing ember, said John. It becomes dimmer and dimmer; it will extinguish itself if left alone. . But blow on it and the chemical reaction responsible for the glowing is intensified. Why does this happen? Because we are delivering oxygen, and removing poisons (carbon dioxide and ashes blocking the unconsumed charcoal.) In the same way a chain reaction based on ^{18}O fuel is intensified (reignited) when favorable conditions are reestablished. Without favorable conditions chain processes are practically inconsequential. The first sustained chain reaction, based on the ^{18}O, ^{7}Li, ^{6}Li and ^{2}H fuels, was accidentally discovered by Fleischmann and Pons, according to Fisher. It is very likely that such processes also happen in our natural environment, for example, in places where fluid agitation is present.

7) Radioactivity of polyneutrons:
John assumes that each neutron in a polyneutron can turn into a proton. This well known and relatively slow process, called beta decay, is associated with the emission of an electron and an antineutrino. After two consecutive beta decays a polyneutron is transformed into a nucleus containing two protons. This makes it possible to eject an alpha particle through a highly exothermic process. The atomic mass of the polyneutron is reduced by four units. The sequence of two consecutive beta decays followed by an alpha decay can then be repeated. This happens over and over again till the size of the polyneutron is reduced to nothing.

A similar process is postulated by John for large composite nuclei. The presence of the ordinary nucleus inside brings some complications but, provided the number of neutrons is large, the shrinking through a relatively slow sequence of beta-beta-alpha decays is possible. Sooner or later, when not too many neutrons are left, even the first beta decay becomes an endothermic process because of the charge on the oxygen member of the composite.

The only way to change the composition, after that stage is reached, consists of a very complicated and a very slow process, the coordinated simultaneous beta-beta decay and emission of an alpha particle.

$$^{16}O\ ^{A}Nt \rightarrow\ ^{16}O\ ^{(A-4)}Nt + {}^{4}He \quad .....(6)$$

The beta-beta-alpha decay half-life becomes very long, for example, 10 years, or so. Slowly decaying composite nuclei can migrate (in air or in water) over long distances before they disappear, or before favorable conditions are found to start a chain reaction.

8) Where do original polyneutrons come from?
A chain reaction based on neutrons must be started with neutrons that are produced in some other way. Likewise, polyneutrons must initially exist to trigger a chain process based on reactions (1) and (3). Where do the first polyneutrons come from? Consider a composite nucleus at the ending stage of its beta-beta-alpha sequence. It might be far away from where it was created (as a poison). Suppose this is a bubbling environment in which conditions are favorable to start a chain process. The only thing needed is a single polyneutron. The decaying composite nucleus is not a polyneutron but it can occasionally emit a polyneutron. This might happen, according to John's theory, through a rare process related to reaction (6) including the emission of an alpha particle.

$$^{16}O^{A}Nt \rightarrow\ ^{12}C^{(A-B)}Nt + {}^{4}He + {}^{B}Nt \quad .....(7)$$

If this polyneutron is emitted in a place where conditions are favorable it will start a new chain reaction.

9) How are the reported experimental facts explained by Fisher's theory?
a) Excess heat, reported by many cold fusion experimentalists, according to Fisher's theory, is mostly generated thorough reactions like (1) and (3), often with ^{7}Li, ^{6}Li and ^{2}H fuels. The outcomes will become reproducible only when we learn how to control favorable conditions.

b) Production of tritium, reported by many cold fusion experimentalists, is, according to Fisher's theory, generated thorough the reaction (2).

c) Production of helium, reported by many cold fusion experimentalists, might, according to Fisher's theory, occur is several ways. Reaction (1') is only one of them. Sequential beta-beta-alpha decays, taking place in the region in which the chain process is going on, is another mechanism for generating helium.

d) Showers of alpha particles, discovered in electrolytic cells by Oriani and Fisher, are consequences of rapid sequences of beta-beta-alpha decays of common composite nuclei.

e) Much larger showers, in the vapor over an electrolyte, also reported by Oriani and Fisher, can be explained as chain reactions supported by reactions (1) and (3), triggered by a polyneutron from the decay of a long-lived composite via reaction (7). Such chains can generate over 100,000 alphas before they are quenched by buildup of composite nuclei in the quiescent vapor.

f) Another way to generate alpha particles, for example in an electrolytic cell containing ordinary lithium, is the following exothermic sequence:

$$^{A}Nt + {}^{7}Li \rightarrow {}^{(A+2)}Nt + {}^{5}Li \quad \text{.....(8)}$$
$$^{5}Li \rightarrow {}^{4}He + {}^{1}H \quad \text{..... (8b)}$$

g) Nuclear transmutations are, according to Fisher's theory, produced through collisions of polyneutrons with ordinary nuclei. The above sequence transmutes lithium into helium and reaction (1) transmutes ^{18}O into ^{16}O. Changes in isotopic compositions of numerous elements were reported by many experimentalists.

I suppose that an appropriate exothermic nuclear reaction, or a sequence of several such reactions, can be found to explain appearance of particular products. Polyneutrons are not repelled by ordinary nuclei and reactions must often be characterized by large cross sections.

h) How would an alchemist, familiar with properties of neutrium, plan to make gold, ^{197}Au, from a common isotope of mercury, ^{202}Hg? The first step would be to realize that the mercury isotope, ^{197}Hg, turns into gold through the well known process of electron capture. This has nothing to do with polyneutrons. The challenging part would be to transmute ^{202}Hg into ^{197}Hg. That is where the use of polyneutrons would probably be suggested, according to the following reaction:

$$^{A}Nt + {}^{202}Hg \rightarrow {}^{(A-5)}Nt + {}^{197}Hg \quad \text{..... (9)}$$

Once produced, the ^{197}Hg will certainly turn to gold. But is the reaction (9) possible? The answer depends on its Q value. According to (2) the mass excesses of the ^{197}Hg and ^{202}Hg are: -30.436 MeV and -27.356 MeV, respectively. Using these numbers one finds that the Q value of (9) is +12.6 MeV. The positive sign indicates that the reaction is energetically possible. A conventional nuclear scientist, who does not believe in polyneutrons, would probably suggest to produce ^{197}Hg from ^{196}Hg with ordinary neutrons. This way of manufacturing gold from mercury is indisputably feasible but too expensive. It is based on conventional nuclear science.

10) Post scriptum:

Fisher's presentation at the conference in Marseilles (5) had no equations. Puzzled by its content I asked John for a private lecture. He agreed. That recorded lecture was attended by three other conference participants: Russ George, William Collis (who said that he learned about Fisher's polyneutron model ten years ago) and by Bielobrzeckaja-Costalariza-Nikolajeva. Most of what I wrote here is my understanding of that lecture, and of the references (4,5). I am

a retired teacher who likes pedagogical challenges. Learning the model and describing it was a real challenge. The content of this essay will be modified to reflect evolution of my understanding.

Appendix 1:
Energy in nuclear reactions.

All nuclear transformations, both reactions and radioactive decays, have an energy aspect. A nuclear reaction, in general, can be described symbolically as:

$$L + K \rightarrow R + S$$

where L and K are isotopes called reactants while R and S are isotopes called products. The number of participants does not have to be limited to two on each side. A transformation with only one term on the left side is called radioactive decay. Similarly, a process with two terms on the left side but only one term on the right side is called fusion. Electrons and photons are not reaction participants in this simplified description. The energy aspect of a nuclear transformation is characterized by the so-called Q value of the process. By definition, the Q value is the difference between the sum of the masses on the left side and sum of the masses on the right side, multiplied by the square of the speed of light, c.

$$Q = [(\text{sum}(L+K) - \text{sum}(R+S)]*c^2$$

A nuclear process is said to be exothermic (releasing energy) when Q is positive; it is said to be endothermic (using energy) when Q is negative. Exact masses of known nuclear isotopes have been determined with great accuracy; their values can be found in most nuclear science textbooks (2, 3). Note that Q is positive when the sum of the masses on the left is larger than the sum of the masses on the right. One way to describe this, no longer popular, is to say that Q is positive when the mass is reduced in a process and Q is negative when the mass is increased in it. The term inside the square brackets, often represented by Dm, is called the reaction mass difference. Using this term the equation (10) can be written $Q=Dm*c^2$. Note that Q is in joules when m is in kilograms and c is in meters per second. In nuclear physics, however, Q is usually expressed in MeV and Dm in so called atomic mass units, u. Using the well known conversion factors associated with these practical units one finds that the value c^2 must be equal to 931.48 MeV/u. Thus Q=9.31 MeV when Dm is 0.01 u, and vice versa. Exact masses in reference (2), given in u, can also be expressed in the units of energy. The mass of ^{58}Ni, for example, 57.935346 u, can be expressed as 53965.616 MeV.

Reference (3), on the other hand, does not give exact masses for each isotope. What it gives instead is called the mass excess. By definition, the mass excess for an isotope (not to be confused with Dm of a reaction) is simply a difference between the exact mass of that isotope, M, and the nearest integer I. It is usually expressed in the energy units, MeV. The mass excess for ^{58}Ni, for example, is -60.224 MeV (3). That value can be used to calculate the exact mass, M, if needed. To illustrate this let me write:

$$(M - I)*931.48 = -60.224$$

where I is 58. This gives; M=57.93534 u found in (2). It turns out that Q values of nuclear transformations can be calculated from the defining equation (10) by using mass excesses instead of exact masses. To illustrate this consider the following reaction:

$$^{1}n + ^{27}Al \rightarrow ^{4}He + ^{24}Na$$

where ^{1}n represents a neutron. The excess masses on the left, according to (3), are +8.071 MeV for ^{1}n and -17.194 MeV for ^{27}Al. Likewise, excess masses on the right are: +2.425 and -8.418 MeV, respectively. This gives -9.123 MeV for the sum of the left and -5.993 MeV for the sum on the right. The Q value of the reaction, is the difference between the sum on the left and the sum on the right; in this case it is equal to -3.13 MeV. Negative Q indicates that the reaction is endothermic. That reaction becomes possible only if at least 3.13 MeV of energy is delivered, for example, in the form of kinetic energy of the neutron.

Appendix 2
Excess masses of polyneutrons etc.

The value of k:

The mass excess of a polyneutron composed of A neutrons, as explained in the main part of this essay, is $\Delta(^{A}Nt) = k*A$. The purpose of this appendix is to show how the Q values are calculated for the reactions involving polyneutrons. Let us see how the numerical value of k 1.90 MeV/u) was established by John Fisher. If the reaction (1) is exothermic, as assumed by Fisher, then its Q must be larger than zero. This implies that the sum of the excess masses on the left side of the equation (1) must be larger than the sum of the excess masses on the right side. Or, symbolically,

$$[D \text{ of } ^{18}O] + [D \text{ of } ^{A}Nt] > [D \text{ of } ^{16}O] + [D \text{ of } ^{(A+2)}Nt] \ldots\ldots\ldots\ldots (10)$$

The excess masses of ^{18}O and ^{16}O are known (3); they are -0.783 and -4.737 MeV, respectively. Furthermore, [D of $^{(A+2)}Nt$] is only 2*k larger than [D of ^{A}Nt] Therefore:

$$-0.783 + k*A > -4.737 + (k*A + 2*k)$$

This reduces to the inequality $k < 1.977$. The upper limit of k is established by John on the basis of reaction (2). Assuming that the Q value of that reaction is positive (otherwise the reaction would not occur spontaneously) one has:

$$[D \text{ of } ^{2}H] + [D \text{ of } ^{A}Nt] > [D \text{ of } ^{3}H] + [D \text{ of } ^{(A-1)}Nt] \ldots\ldots\ldots\ldots (11)$$

The excess masses of ^{2}H and ^{3}H are known (3); they are 13.13 and 14.95 MeV, respectively. Therefore,

$$13.13 + k*A > 14.95 + k*(A-1)$$

The k*A cancels, because it appears on both sides of the inequality, and one has; $k<1.82$ MeV/u. In other words, positive Q values of the reactions (1) and (2) implies that k must be confined to a narrow range of values:

$$1.82 < k < 1.98$$

The value used by John, 1.90, is in the middle of that range. Knowing k we can calculate the Q value of any nuclear reaction involving polyneutrons. This in turn, allows us to predict which reactions can occur spontaneously and which can not.

Only reactions whose Q values are positive can take place spontaneously. Reliability of such predictions, however, are only as good as the reliability of Q values. That is where a difference between ordinary nuclear reactions and reactions involving polyneutrons become obvious. Exact masses of ordinary nuclei have been measured before the theoretical model (for calculating them) was introduced in 1930's. The model has several numerical coefficients; their values were chosen to match the experimentally measured masses. Polyneutrons, on the other hand, are hypothetical particles whose exact masses are unknown outside the theoretical model. What would the range of k be if another pair of hypothetical reactions, instead of (1) and (2), were chosen? How to decide that one choice of possible defining reactions is better than another? I suppose that such questions are premature at this preliminary stage of development. It is a miracle that a pair of reactions narrowing the range of possible values of k to plus or minus 0.4% was found by John.

Fisher's theory, described in the main text of this essay, introduces molecule-like structures called composites. The $^{16}O^{B}Nt$, appearing in the reactions (4) and (5), is a typical example. The excess mass of such loosely bound structure is assumed to be the sum of the excess masses of the ordinary nucleus, such as ^{16}O, and of the excess mass of the polyneutron, such as ^{B}Nt. What is the Q value of the reaction (3)? The first step, as always, is to write down the defining equation:

$$Q = \text{sum (of all D on the left side)} - \text{sum (of all D on the right side)}$$

or, more specifically,

$$Q = [\ D \text{ of } {}^{A}Nt + D \text{ of } {}^{18}O] - [D \text{ of } {}^{16}O + D \text{ of } {}^{B}Nt + D \text{ of } {}^{C}Nt]$$

Note that to balance the numbers of nucleons the (A+18), on the left, must be equal to (16+B+C) on the right. In other words, A+2 must be equal to B+C. The excess masses of ^{18}O and ^{16}O, according to the reference (3) are: -0.783 MeV and -4.737 MeV, respectively. This gives

$$Q = [k*A + (-0.783)] - [(-4.737) - k*B - k*C]$$

or

$$Q = 3.254 + k*(A - B - C) = 3.254 + 2*k = 7.054 \text{ MeV}$$

The reaction is exothermic. In the same way one can show that the Q value of the reaction (4) is equal to 4.454 MeV. Answering one of my e-mail questions John wrote:

"The excess masses you are using for ^{1}Nt, ^{4}He, and ^{16}O are correct. They are respectively +8.071 MeV, +2.425 MeV and -4.737 MeV. The mass excess of ^{18}O is -0.782 MeV. My best estimate of the mass excess of polyneutron with A neutrons is 1.90*A MeV. This makes the mass excess of ^{16}O stuck to a polyneutron with 100 neutrons, $^{16}O^{100}Nt$, equal to -4.737 + 190 -b where b is the binding energy of the oxygen to the polyneutron drop. I don't know what b is, but I assume it is small. In any event it does not matter for most reactions. Consider for example the polyneutron growth reaction (1):

$$^{100}Nt + {}^{18}O \rightarrow {}^{102}Nt + {}^{16}O$$

wherein the polyneutron grows by two neutrons. The energy generated in this reaction is:

$$(190 - 0.78 - b) - (193.8 - 4.74 - b) = -3.8 - 0.782 + 4.737 = 0.16 \text{ MeV}.$$

so the polyneutron growth reaction is exothermic and ^{18}O is capable of supporting a chain reaction. Note that the b's cancel out. Now consider the decay of the composite, $^{A}Nt\ ^{16}O$, where a polyneutron and ^{16}O are stuck together. The composite can decay by simultaneous double beta decay and alpha decay in a reaction with the overall formula:

$$^{A}Nt^{16}O \rightarrow {}^{(A-4)}Nt^{16}O + {}^{4}He$$

Here the energy generated is:

$$Q = [1.90*A - 4.74 - b] - [1.90*(A - 4) - 4.74 - b] - 2.42 = 5.18 \text{ MeV}.$$

Keep your questions coming. I will answer them all if I can, on the first try if possible."

Appendix 3
Other chain processes?.

1) Tables of excess masses are often shown in nuclear physics and nuclear chemistry textbooks. Here are some of the excess masses from the reference (3). They can be used to calculate Q values of reactions mentioned in my essay.

Atom Δ(of atom) in MeV
==========

^{1}Nt (neutron) 8.071
^{1}H 7.289
^{2}H 13.126
^{3}H 14.950
^{4}He 2.425
^{5}Li 11.680 (According to J. Fisher; ^{5}Li is not listed in reference (3))
^{6}Li 14.087
^{7}Li 14.908
^{12}C 0.00000
$^{16}0$ - 4.737
^{18}O - 0.783
$_{27}Al$ - 17.194
^{58}Ni - 60.224
^{93} Kr - 65.6

^{133}Cs - 88.089
^{142}Ba - 77.82
^{197}Hg - 30.735
^{197}Au -31.567
^{202}Hg - 27.356
^{235}U 50.572
^{238}U 47.307
^{239}Pu 48.585
^{A}Nt (large A) 1.90*A

To practice with calculations of Q values the reader is invited to verify that the two reactions shown below are endothermic (negative Q).

$$^{A}Nt + {}^{7}Li \rightarrow {}^{5}Li + {}^{(A+2)}Nt \quad \text{.....(12)}$$
$$^{A}Nt + {}^{7}Li \rightarrow {}^{6}Li + {}^{(A+1)}Nt \quad \text{.....(13)}$$

Show that their Q values are -1.80 MeV and -0.57 MeV, respectively. The reaction (14), however, is exothermic; its Q value is 9.32 MeV. That indicates that polyneutrons can grow by interacting with deuterium, for example, in heavy water.

$$^{A}Nt + {}^{2}H \rightarrow {}^{(A+2)}Nt \quad \text{.....(14)}$$
$$^{A}Nt + {}^{2}H \rightarrow {}^{B}Nt + {}^{C}Nt \quad \text{..... (15)}$$

In other words, heavy hydrogen (^{2}H), like heavy oxygen (^{18}O), can be a fuel in the chain process. A sequence of reactions (14) followed by the reaction (15) constitutes a single step in the energy generating chain process. This is similar to the process based on the reactions (1) and (3).

2) Suppose an electrolytic cell is used to create “favorable condition” for the chain process based on either reactions (1) and (3). or reactions (14) and (15). Excess heat is produced coninuously because the exothermic chain reaction is going on. Fresh fuel, ^{18}O or ^{2}H, is supplied and poisons are removed, as envisioned by Fisher. Suddenly one gram of ^{238}U is introduced into the electrolyte, for example, in the form the powdered uranium nitrate salt. I am speculating about production of ^{235}U from ^{238}U via the following reaction:

$$^{238}U + {}^{100}Nt \rightarrow {}^{235}U + {}^{103}Nt$$

Is this possible? No, it is not possible, because Q is equal to -8.95 MeV. The reaction is endothermic; it will not occur spontaneously, fortunately for our safety.

3) Then I envision a well known precess -- spontaneous fission of ^{238}U according to the following reaction:

$$^{238}U \rightarrow {}^{142}Ba + {}^{93}Kr + 3*({}^{1}n) \quad \text{.....(16)}$$

Uranium decays by emitting two fission fragmens (barium and krypton) and three free neutrons. The above fission products are known to be beta radioactive. Using the excess masses of participants one finds that Q=166 MeV. The process is strongly exothermic but the probabilty of its occurence is extremely low (due to the fission barrier of about 6 MeV). But can this process be speeded up by polyneutrons? I am imagining, for example:

$$^{100}Nt + ^{238}U \rightarrow ^{142}Ba + ^{93}Kr + ^{103}Nt \text{.....(17)}$$

The Q value of that reacion is 190.5 MeV. Conceptually it is similar to the reaction (1') where ^{7}Li was split into two fragments (^{4}He and ^{1}H) by interacting with a polyneutron. In both cases the polyneutron grows and energy is released. The released energy in the reaction (17), however, is much larger than in the reaction (1'). The reaction (17) implies that the fission barrier of the ^{238}U is somehow overcome in the presence of the ^{100}Nt. Note than the polyneutron of mass 103, escaping from the reaction, might interact with another ^{238}U, etc. Is it conceivable that one can have a fast chain reaction in which ^{238}U is generating excess heat? I do not know how to answer this question.

Addendum (5/27/05):
A revised version of the polynutrons theory, as presented iby John Fisher in Siena (May 2005), is described in a paper that can be downloaded from his website:

http://www.markfisher.net/johnfisher/papers/neutron_isotopes_slides.pdf

My comments about the new version can be seen in unit #226.

Inserted on on 7/14/2009:
A recent qoute of what John Fisher wrote can be seen at the beginning of Unit 364. And here is another message that John posted on CMNS list: Responding to a question about polyneutrons, he wrote: "I have returned from vacation after several weeks and now can answer your question regarding the sticking force between neutrons in a polyneutron.

First note that two neutrons are almost bound into a di-neutron. They form a resonance with energy about 0.12 MeV over a potential well about 35 MeV deep. (For references see Treatise on Heavy-Ion Science, Vol. 8, Nuclei Far From Stability, Edited by D. Allan Bromley, Plenum Press, 1989, p 313 for 0.12 MeV resonance, and also Kenneth S. Krane, Introductory Nuclear Physics, John Wiley & Sons, 1988, p 82 for 35 MeV potential well.) We see that two neutrons are very strongly attracted to each other, but not quite strongly enough to be bound.

Consider now a large cluster of neutrons having density comparable to that of ordinary nuclei. Except for surface neutrons, each neutron is surrounded by 12 other neutrons with which it has nearest-neighbor interaction. This implies a 12-fold increase in the potential well that it sees and assures that it is strongly bound to the cluster. Neutral pions are the particles to which most of the attractive force can be attributed. Although the binding energy cannot be computed from first principles (it cannot be computed for the neutron-proton clusters of ordinary nuclei either) it can be approximated by a liquid drop model with a negative volumetric energy term and a positive surface energy term. The strengths of these terms can be determined from experiment (LENR experiments) just as they have been determined by ordinary experiments for ordinary nuclei.
From LENR experiments I have been able to determine an approximate value for the volumetric binding energy term, and find it to be about half of that for ordinary nuclei."

192) Oriani solid effect at my lab

Ludwik Kowalski (December 1, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

One can consider this to be a continuation of my unit #188. It is an open electronic logbook to tell what I am doing in trying to observe Oriani-solid effect for the third time. Part of the experiment is to be performed at my home (electrolysis) and part at Montclair State University (where the microscope is located). Here is what I have done so far.

1) CR-39 detectors were put in contact with everything to be used (for 7 days) in the cell: (Ni foil, glass tube, O-ring, powdered Li2SO4, water and platinum.) I will etch these detectors tomorrow . But will not waste time on counting tracks until this becomes important.

2) The cell was assembled (as illustrated in Figure 1 of the unit #188) and I used water to make sure there is no leak. The Pt wire (0.5 mm diameter is rigid enough to be used without a stopper. About 13 cm of the wire was enough to make a horizontal spiral and the vertical lead with a hook). The hook goes over the rim of the upper tube; that keeps the cathode in a fixed position. The horizontal spiral, anode. is 13 mm above the nickel foil (cathode). The amount of electrolyte above the cathode is about 4 cm.

3) The experiment started at 23:30 today (December 1, 2004). To get the current of 0.10 A I had to raise the potential difference across the cell to 7.5 V. That is how the cell is running now. At the very beginning I checked how the current depends on the voltage; the cell needs 16.5 V to have the current of 0.30 A. The cell does not behave as a linear resistor. I noticed that it is not very stable. Each time I return to the same current I need a slightly different voltage. I guess this has to do with the fluctuating number of bubbles. The electrolyte of milky, as it was in Minneapolis.

4) Four CR-39 detectors were positioned: one below the cathode and three along the outer walls of the upper tube. Oriani told me that he often detected particles in detectors facing the tube. Note that the upper tube is open and that the detector placed below the Ni cathode (in the air) is only 1.5 mm away. In that way the geometry of exposing the cathode to CR-39 will be essentially the same during the electrolysis and after the electrolysis.

5) More tomorrow; it has been a busy day (the day on which the DOE report was finally released).

December 2, 2004

6) It is hard to sleep when a decisive experiment is running. The voltage needed to keep the cell current at the 0.10 A level is now very steady; it is 7.0 V. It was 7.5 V when I went to sleep. Also bubbling is much less intense. I suppose that the bubbles seen during the beginning of the electrolysis were mostly air. (P.S. some water evaporated. I ˇrestored the level of electrolyte by adding about ten drops of water. This was done with a pipette while the cell was running. In this way the concentration of the electrolyte was restored. The voltage needed for 0.1 A is again close to 7.5 V. The volume of the electrolyte in my cell is 9 cc; most of it is in the column above the anode.)

7) I think that I should place a fresh CR-39 chip below the cathode when I double the current. I can easily do this without turning the current off. Why not? If particles I expect to detect are as numerous as they were in Minnesota then my track density after 24 hours is much higher, because my detector is nearly in contact with the cathode. And I might see particles that would be filtered by 1.5 cm of air.

8) The volts-amps relation for my cell (Ni cathode and Pt anode separated by 13 mm) is not linear. Why? The electrolyte was made by dissolving 2.36 grams of Li2OH4 in 100 cc of H2O. Does it imply avalanching of ions? Keep in mind that this open electronic logbook Kis for those who are interested in details and, perhaps, performing the experiment at the same time. I hope some of them will answer my question (by sending a message to me at , or comment on what I am doing.

9) Richard Oriani who I asked about the voltage needed by cell seems to be larger than that needed by his cell, wrote: “A voltage of 7.5 volts is perfectly acceptable. You must remember that most of the voltage is used to overcome the resistance in the electrolyte. Apply whatever voltage is necessary to get the current that you want.” But then he added. “I hope that you etched and counted preexisting tracks before the electrolysis.” No I did not do this; I have a control chip, several meters away from the cell. It will give me the background to subtract. Oriani’s approach is essential when one d Ieals with situations in which the signal is only several times larger than the noise (background). The success for me, in this first experiment would be a signal similar to that we had from two experiments

in Minnesota. Repeatable strong effect is needed to convince skeptics. Yes, I know that even this is likely to be “not enough.” What motivates me, at this stage, is confidence in scientific ways (as opposed to bureaucratic ways) of solving controversies in natural sciences.

10) It would be so much easier to work with an electronic (surface barrier) detector. Instead of waiting days I would know what happens each hour. I hope that somebody with that instrument, after reading this logbook, will construct a similar cell to study Oriani-solid effect. Please send them to me and I will be happy to post them in a dedicated unit.

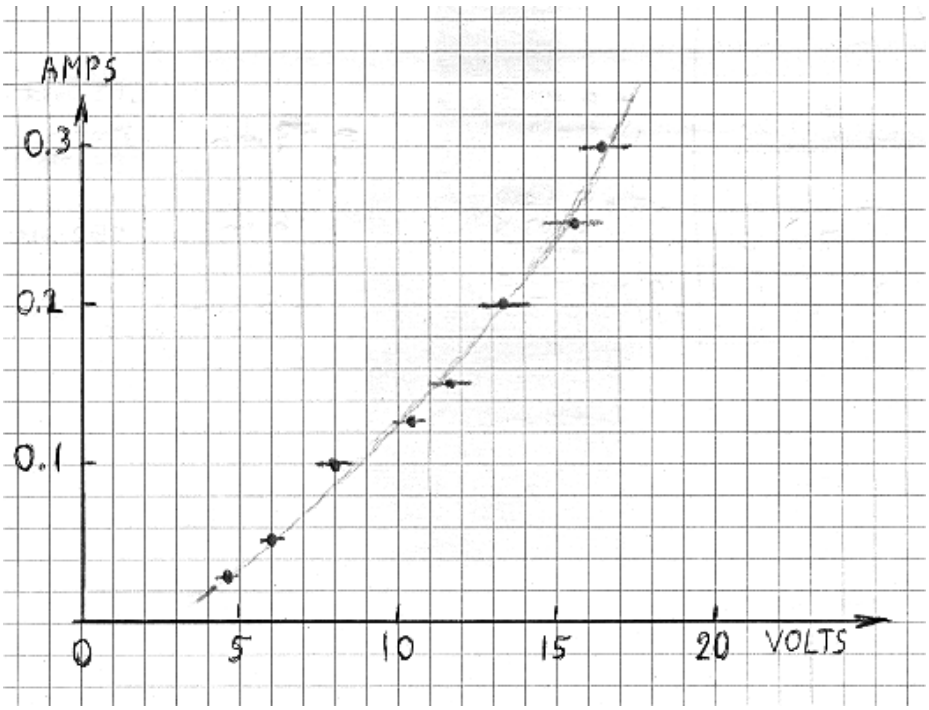

Figure 1

11) Pictures showing my cell. Figure 2 is the operating cell. Note the three CR-39 detectors (two very small and one much larger) facing the upper tube. The detector below the cathode is not visible, only its pedestal. The screws pressing the flange joints toward each other are also the legs on which my open cell is standing. Figure 3 shows the cell and its spiral platinum wire (before the unused part of it was cut). The HCl (1 N water solution) was used to wash platinum (for 24 hrs) to remove possible dirt introduced by my fingers (in making the spiral cathode). That what Oriani does.

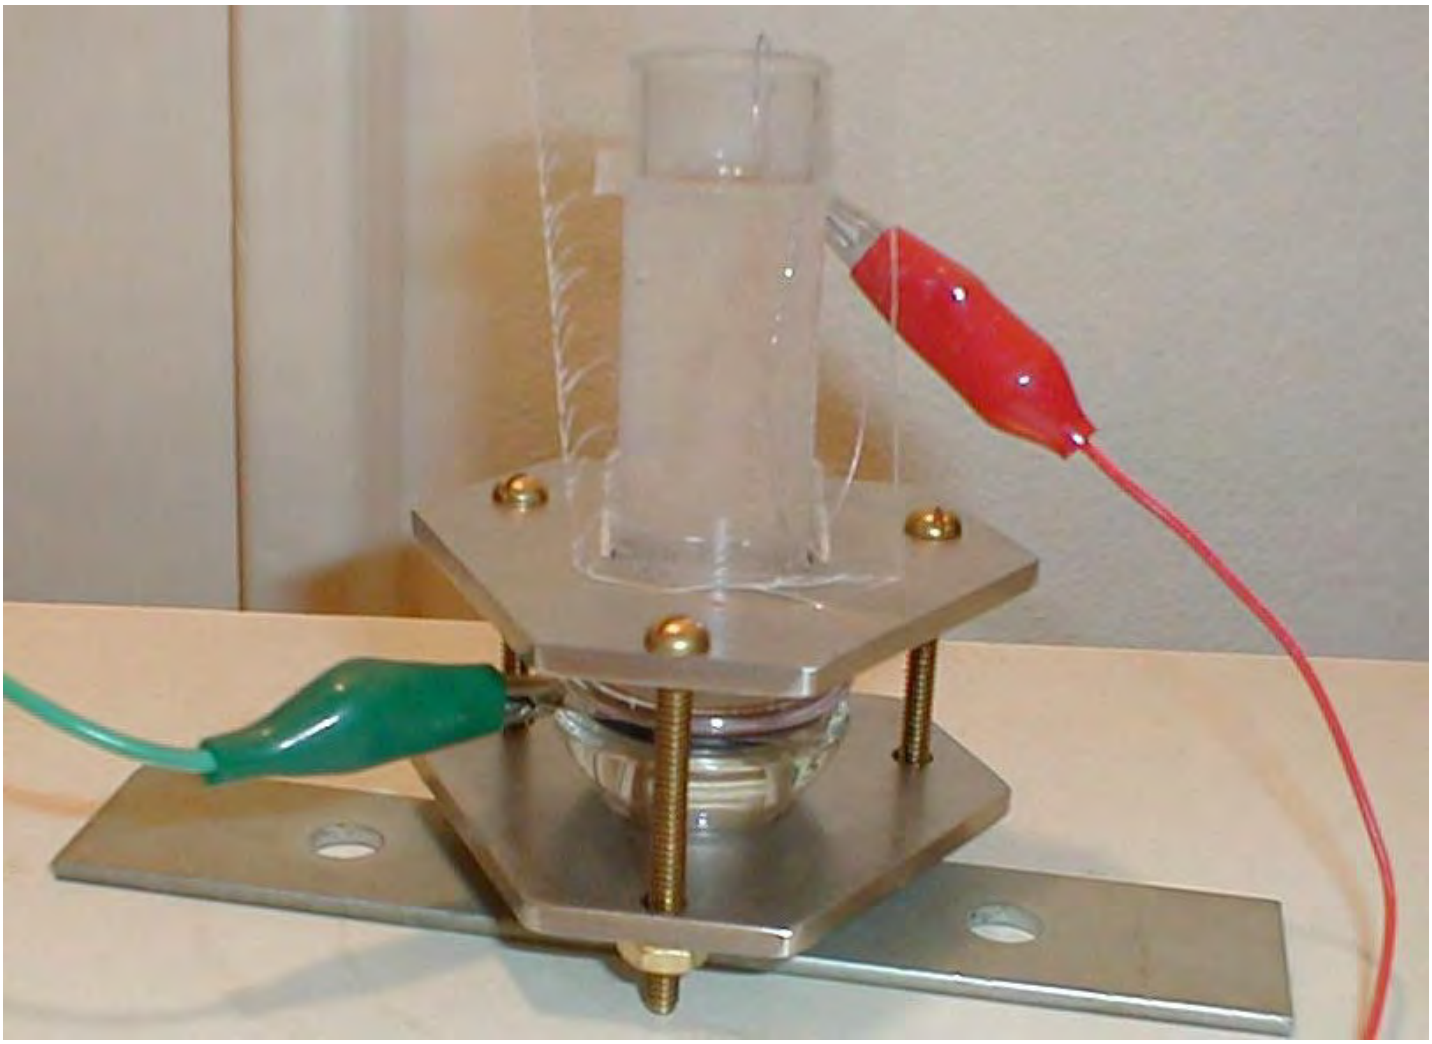

Figure 2

12) The voltage needed to keep the current constant changes from time to time. Sometimes it goes up or down by 10% or so. I suppose this has to do with changes occuring at the surface of the cathode. To keep the concentration of the electrolyte constant I add drops water, every several hours or so.

13) In the spirit of trying to reproduce the November 16 experiment in Minneapolis I decided not to change CR-39 detectors when I change currents, first to 0.20 A (tonight) and then to 0.30 A (tomorrow night). The third detector will remain in place for 24 hours (when I will be 0.3 A). Then the current will be cut off and the fourth detector will be used for about 24 hrs. This will be the first post-electrolysis exposure. It will be followed by the second and third exposures, for example, 24 hours each. Stay with me to share the excitment. I do not know if that excitment will come from a confirmation of the two effects or from the failure to confirm. The effects are: (a) emission of nuclear particles from the cathode during the electrolysis and (b) emission of such particles after the electrolysis.

14) An interesting observation. In watching the cell and the ammeter for about 15 minutes I noticed repetitive oscillations of the current. The current remains constant for about 3 minutes. During that time tiny bubbles are rising along the upper tube, like smoke in air. This must be oxygen and hydrogen. Then, for about one minute, the current starts decreasing monotonically (from 0.10 A to about 0.6 A). The tiny bubbles are rising as before. At one moment, however, I see a big bubble of gas (perhaps one cc) escaping through the tube. It is probably created below the cathode. Once this big bubble is out the current returns to 0.10 A and the cycle repeats itself. I suppose that the drop of current reflects the growth of the big bubble in the electrolyte between the cathode and the anode. (it changes the resistance). But can big bubbles be explained? I have no idea. If they are mixtures of hydrogen and oxygen then they are probably dangerous.

15) That is not what I observed after changing the current from 0.10 to 0.20 A (at 20:30 after using the current of 0.1 A for 21 hours). The intensity of tiny bobbles did increase, as expected, but big bubbles were popping up again, very regularly. This time I measured durations. After remaining constant for 43 seconds (I=0.20 A) the current started to go down to 0.12 A for 35 seconds. Then it jumped

back to 0.20 A and the cycle repeated itself. Sudden returning to 0.20 A always coincided with big bubbles. Perhaps the shape of the anode could be designed to prevent this. On the other hand, the big bubbles may be growing on scratches Oriani said might play a role. In any case I observe a dynamic process that may somehow be responsible for a nuclear phenomenon. After all, some well known phenomena depend on the rate of change of current rsther than on the current itself. Yes, I know, such speculations are more poetic than scientific. I do not have a theory to guide me; this is a facts-gathering experiment. The task is to confirm, or to cotradict, a clame made by Oriani. The claim is that an electrochemical process induces emission of nuclear particles.

16) Aha; by watching at a proper angle (through the conical part of the flange joint) and after optimizing the illumination, I was able to observe growing of large bubbles. This happens below the spiral anode, at a point there the cathode and the inner surface of the tube touch each other. Just before escaping the layer of gas covers abour 1/4 of the surface of the anode. I guess the diameter of my spiral anode should have been slightly smaller, and spaces beteen the widings a little larger. Then there would be no current fluctuations due to big bubbles.I guess the diameter of my spiral anode should have been slightly smaller. Then there would be no bubbles, I think. The temperature of the electrolyte, at 0.20 A, is 28 degrees C (measured by inserting a mercury thermometer for about two minutes).

December 3, 2004

17) So far the current was 0.10 A during the first 21 hours and 0.20 A during the next 24 hours. I just changed it to 0.30 A. The big bubbles now come every 40 seconds; During that time the current changes from 0.30 A to 0.1.80 A. My average current is thus close to 0.24 A but I will call 0.30. In the same way the so-called 0.20 A was actually a little bit smaller.

18) Before changing the current I removed one of the two small CR-39 detectors that were positioned next to the glass tube in air. A fresh Cr-39 detector was placed into the same position. I want to know if the higher current produces more tracks per hour than the lower currents. I still have two detectors that will be been exposed to glass for the entire time of electrolysis. And the detector under the nickel cathode will be replaced only after the current is turned off.

19) It is clear that the water level goes down more rapidly than before. Water escapes after being decomposed into oxygen and hydrogen; its temperature is now 49 C. It takes about three hours to lower the level of water by one centimeter. I will have to add water more often now (to keep the concentration more or less stable), for example every two or three hours.

20) What is the etching time? I already know, form experience, that the NaOH, whose temperature and concentration are 65 C and 6.5 N, etches very well in about 6 hours. Etching times that are too short produce tracks that are too small (hard to distinguish from dirt). Too long etching times might destroy shallow tracks (by taking away the layer in which they reside). To decide the optimum etching time (CR-39 from two different suppliers) I irradiated small detectors with alpha particles and etched them for times of 2, 4, 7, 9.3, 12.5 and 14.5 hours. A similar task, for CR-39 from the third supplier, was assigned to a student working with me on something else (radon detection project). One CR-39 chip, from the material she is using, was etched for 5.5 hours.

I will examine all these chips tomorrow. But how do I know that what is best for alpha particles (my Am-241 source was removed from an ionization fire alarm) is also best for the unknown particles coming out of the cathode? That is the dilemma. Without knowing what these particles are one has to be lucky to make the best compromise. It is possible that the numbers of tracks counted by Oriani were due to a small fraction of particles that were actually intercepted by the detector. Some of his observations (not yet published) are consistent with this. That is why I decided to position my detector only 1 mm from the cathode (rather than 15 mm as we had in Minneapolis) two weeks ago. No harm can result from bringing the detector closer.

December 4, 2004

21) Today I measured diameters of pits (tracks) made in CR-39 by alpha particles emitted from my Am-241. Etching times were from 2 hours (the shortest) to 14.5 hours (the longest). I used the NaOH of 6.5 N and 65 C; the chips were from Landauer. (see item #184). Tracks become visible after 2 hours, but their diameters were too small (about one micron). Such tracks are hard to recognize because other small dots (dirt, and surface deffects) are also present. At four hours the track sizes are close to 3 microns. Then their sizes grow linearly with up to about 14 microns for the etching time of 14.5 hours. I would not be surprised to see a different curve for 2 MeV because their tracks are shallower. I will etch my detectors for ten hours; this produces pits which are easy to recognize, even when the surface of the detector has scratches and dirt. Cr-39 from two other suppliers (see item #184) produced essentially the same track diameters as those from Landauer after the etching time of 5.5 hours.

My advise to those who want to study CANA phenomena (Chemically Assisted Nuclear Activity) with CR-39 detectors should always produce a chip irradiated by alpha particles. That chip should be etched together with other experimental detectors. In that way one can always be sure that etching conditions were satisfactory. Trivial mistakes, such as wrong concentration of NaOH, or using a plastic chip that is not CR-39, would be immediately recognized.

22) I changed my mind, after writing the above. I will etch my chips twice, first for 6 hours and then for another 6 hours. This will give me a chance to examine the chips twice; I do not want to miss a chance of seeing tracks that might disappear after 10 hours of etching.

23) I will end the electrolysis tonight. For some reason the current is no longer oscillating; the big bubbles stopped popping up. perhaps the room temperature, or pressure, is not the same as yesterday. Yes, I know that a pathological skeptic might say: “Your experimental results can not be taken seriously because you are not controlling all parameters.” But s/he would say this only if a lot of nuclear particles were detected; the failure to confirm Oriani’s discovery would be applauded. Why wasn’t scientific methodology used by scientists appointed by the DOE to reevaluate cold fusion claims? Instead of trying to replicate selected experiments, such as generation of helium or emission of protons, they asked for written reports. Then they wrote what they think about the reports. I would prefer them to be investigators, nor jurors.

Scientific disputes should be addressed scientifically. The Oriani effect I am investigating (with nickel and ordinary water) can not be “cold fusion.” I never met a scientist who thinks that “cold fusion,” a reaction in which two isolated deuterium ions fuse at ordinary temperatures, is possible. Was the effect Oriani effect examined by the DOE jury? What did the jurors know about it? One day before the DOE review report was published -- what a coincidence -- I sent an e-mail massage to the DOE investigators (via Dr. Decker). It was a reference to my already-posted unit #188. This was too late to influence the outcome of the DOE report. But was my message delivered to them? I do not know.

27) The current of 0.30 A has been flowing through the cell for nearly 25 hours; it will soon be cut off. Before doing this I want to describe what I am going to do next.

a) Removing the Pt anode and applying a detector to it.

b) Emptying the electrolyte into a small beaker and dropping a detector into it.

c) Removing the upper tube and applying four detectors to the nickel cathode, on the side that was wet during the electrolysis. Each of these four detectors has the area of one square centimeter, just enough to cover the entire foil (including the areas that were not in contact with the electrolyte).

d) Removing the detector that was below the nickel foil during the electrolysis and replacing it with a fresh detector. The counting geometry will be exactly the same as during the electrolysis. All fresh detectors will remain in place till tomorrow. After that they will be removed and replaced by fresh detectors. Then the removed detectors will all be etched and examined.

The name of the game is good labeling and good documentation. Preliminary results of observations will be posted here, probably not later than on Monday. Further plans will depend on these results. My wife said that since the effect is known to be only 60% reproducible, and since I was lucky to see it twice, then “it is about time” for a failure. She said this laughingly, of course.

28) All went as anticipated. The current during the electrolysis was 0.10 A during the first 21 hours, 0.2 during the next 24 hours and 0.30 in the remaining 25.5 hours. The end of the electrolysis was at 22:00 on 12/4/04. That will be called “zero time” for the rest of the experiment (in case particles are emitted after the end of electrolysis), as they were in Minneapolis.

December 5, 2004

29) Five Cr-39 chips are being etched now:

```
(A) was below the nickel cathode (1 mm away in air).
(B) was several meters away to measure the background.
(C) was in contact with glass (outside the tube) at all three currents.
(D) was in contact with glass (outside the tube) only at I =0.1 A and 0.2 A.
(E) was in contact with glass (outside the tube) only at I =0.3 A.
```

The first post-electrolysis accumulation of tracks (on chips listed below) will continue. For how long? It depends what I will see on the chip (A) after 6 hrs of etching (in about an hour). If I see a lot of tracks then I will stop the accumulation at once and will start another one with fresh detectors. Otherwise I will wait another day or two.

```
(F1, F2, F3, F4) are in contact with the cathode (on the side that was wet).
(G) is in contact with the cathode (side that was dry during the electrolysis).
(H) is in contact with the platinum anode (on the surface that was facing the cathode).
(I) is in contact with the electorolyte (floating on top of in a beaker).
(J) is in contact with the inner wall of the upper tube.
(K) is outside to measure the background.
```

30) I did stop etching after 6 hours and examined the chip (A). I did not see any obvious tracks. Therefore I decided to etch all five chips (from A to E, as above) for another six or seven hours. I would have to wait till tomorrow to know if the expected effect was confirmed in another attempt to replicate it. If it is not confirmed then I will repeat the experiment two or three more times. Failure to confirm several times could be an indication that the cell used in Minneapolis was somehow contaminated with an alpha radioactive substance. One does not need a lot of thorium, or uranium, to generate several alpha particles per hour. On the other hand, the idea of contamination seems to be conflict with the fact that Oriani often fails to observe the effects in his cell. A contaminated cell would always produce

excessive tracks, not only 60% of the time.

31) The following message from Oriani, received last night, might provide another explanation of my anticipated failure. Richard wrote;" . . . In view of our ignorance of what concentration is best for the nuclear effect it is probably wise to let the concentration vary over a large range by letting the electrolyte volume decrease a great deal before adding water to replenish the solution....." By adding water frequently (to keep the level of the electrolyte constant) I was not allowing the concentration to change. In other words, my first experiment at home might have missed the necessary concentration. Another explanation might be in water. Trying to follow Richard's footsteps I used tap water. But who said that water in New Jersey contains same impurities as water in Minnesota? The secret might be in the impurities.

I have to wait till tomorrow, and examine other chips, before recognizing failure to confirm the effect in this particular experiment. Well, I should not speculate too early. Perhaps I will see tracks tomorrow, or in the next experiment.

32) Yes, I do have to wait till tomorrow but I already know what to expect. After the end of the second etching, this afternoon, I examined two CR-39 chips: the one that was exposed to alpha particles from Am-241 and (A) that was below the nickel cathode during the electrolysis. I saw a lot of alpha tracks on the first chip, as usual, but only some tracks on (A). The (A) chip was etched for 6+6 =12 hours but the alpha particle chip was etched for the last 6 hours only. (Unfortunately, I forgot to use an alpha irradiated chip to show that etching was normal during the first 6 hours.). It will be a matter of counting tracks on the (A) and (B) chips. Is the track density on (A=signal) significantly larger than on (B=noise)? I will know tomorrow. The situation reminds me the analysis of the TiDx foil from Steven Jones; it is definitely not comparable with what was observed from the Pd613 or Pd616 cathodes sent to me by Dennis Letts.

Why didn't I see tracks on (A) after the first 6 hours of etching? Perhaps the temperature went down after it was initially setting it to 65 C. I was not adjusting it all the time, as during the second etching. To compensate for the possibly too low temperature the second etching was at performed at 68 V. Or perhaps an error was made in the preparation of NaOH (imposing a concentration that was lower than 6.5 N). I will never know because I forgot to etch an alpha irradiated chip.

December 6, 2004

33) Yes, today I have the bad news and the good news to share. But before doing this let me ask you for a favor. If you are among those who read this logbook from day to day -- I suppose there are such people -- then please send me an Emil note at: And I would very much like to hear from those who are trying to replicate Oriani solid effect, as I am. This experiment should not be performed by students without supervision. Chemicals are dangerous, especially hot and concentrated NaOH used for etching. I am sure that many teachers would be happy to supervise student experiments, if you ask.

Using the Internet to share an ongoing experiment, and receiving feedback (criticism, advise, comments), is something I did not do before. Yes, it does take some extra time. I want to know if this time is worth spending. That is why I want to hear from you. Please let me know what you think about the "lab over the Internet" idea. I think that a project in which several people perform the same experiment at the same time and communicate constantly (which did not materialize this time), is worth trying.

34) And now back to our project. Let me tell you what I did today.

a) **Sample (A)** --> 21 tracks (plus or minus 6) on the entire area of 0.7 cm^2.

b) **Sample (B)** --> 28 tracks (plus or minus 10) on the entire area of 0.5 cm^2.
In other words, the detector below the cathode registered nothing but the background. The effect observed in Minneapolis was not observed in Montclair. Perhaps the scratches I made on the nickel foil were not deep enough for the particles to come out. The "plus or minus," by the way, refers to border cases; it is not always easy to decide which dark spots are tracks and which are not. i call this a threshold of rejection error. That error can be reduced to nearly nothing by using an approach invented by Oriani. He etches the chips before the experiments and after the experiment. After the first etching he photographs detector's surfaces, field by field (through a microscope equipped with a digital camera). After the second etching he photographs the same fields. This gives him two pictures for each field. He compares them and counts only those tracks that were absent before the experiment. Such labor-intensive method is much better that my approach -- using one detector for the "signal" and another detector for the "noise."

Expecting a strong signal, similar to that seen in Minneapolis, I decided to follow a much less labor-intensive approach.

c) **Sample (C)** --> 34 tracks (plus or minus 10) on the entire area of 0.6 cm^2. In other words, one of the three CR-39 detectors that were in contact with the outer surface of the upper tube (during the electrolysis), registered nothing above the background.

d) **Sample (D)** --> 47 tracks (plus or minus 15) on the entire area of 0.6 cm^2. A small excess of tracks, with respect to the background is not significant. In other words, the second CR-39 detectors that were in contact with the outer surface of the upper tube (during the electrolysis, when the current was 0.10 and 0.20 A), registered nothing significant above the background.

e) **The big surprise** came when I turned to the third detector (E) that was also exposed to the outer surface of the upper tube. But it was exposed only when the current was 0.30 A, not during the entire electrolysis time, as detector (C). Here I at once noticed a large number of tracks. At first I thought it was a very high background because tracks were present not only on the surface facing the tube but also on the surface facing the air in the room. All other detectors were from Landauer; the (E) detector, received from Oriani, was from Italy (see the unit #185). Its thickness was 1 mm. Before using this new CR-39 material I irradiated another chip with alpha particles and etched it for 5.5 hours. The pit diameters were essentially the same as in the material from Landauer.

Fortunately, the background for the new material could be determined by examining the other surface of the irradiated field. I did count background tracks; they turned out to be much less numerous (about a factor ten or so) than on surfaces of the (E) detector.

```
The average number of tracks (per field of observation) were:

11.1 for the surface of (E) that was facing the outer surface of the glass tube.
14.5 for the surface of (E) that facing the room air.
```

The number of tracks on the first surface was 133 (12 typical fields) and the number of tracks on the second surface was 189 (13 typical fields). The work was done under low magnification of 40. The area of each field of observation, on the monitor connected to the digital camera, was 1.30 square millimeters. In other words, track densities were 850 and 1110 per square centimeter, per 25 hours (time during which the current was 0.30 A). That counting rate, about 40 per hour per square centimeter, is of the same order as reported, for a different setup, by Steven Jones (2).

35) The most surprising fact is the presence of tracks on two detector surfaces separated by one millimeter of plastic material. I think I know how this can be interpreted. Last year, in preparation for detection of protons from the TiDx foils, I often irradiated CR-39 chips by fast neutrons emitted by our Pu-Be source (no longer available). I always observed tracks on both surfaces, more on the second than on the first. Smaller tracks were interpreted as due to collisions between neutrons and protons; about two times larger tracks, much less common, were attributed to alpha particles from (n,a) reactions.

I think that tracks recorded in the (E) detector indicate emission of neutrons, from somewhere within the cell. But why were similar tracks not recorded in the (C) and (D) detectors? I do not know how to answer this question. One way to check if tracks are due to neutrons would be to etch the chip for a very long time (for example, till its thickness is reduced to 0.5 mm). Latent tracks due to neutrons must exist within the entire CR-39 volume. Therefore, new tracks would appear as the old tracks are etched away from exposed surfaces. In other words, visible tracks would be present, even after very long etching. Tracks due to a contamination of both surfaces, on the other hand, would disappear. I will perform this convincing test. Yes, I know, reading reports like this one is below the threshold of dignity of many scientists. The curse put on the entire field of CANA research will continue affecting attitudes toward it. By CANA I mean “chemically assisted nuclear activity.”

36) What Oriani and I have done, after the last conference, would be sufficient to publish a paper, and to apply for a research grant in any other field of natural science. But in the CANA field the only way to communicate with other scientists is the Internet. We know that most of them will not read our reports. And we will continue using our retirement money on research and traveling. That is not how serious research is conducted in other areas of science. Why should it be so? I expected the situation to change after the second DOE-sponsered investigation. But now I know that this will not happen very soon.

I wish I had access to a neutron detector. Another useful thing to do is to cover the entire tube with CR-39 detectors and then look for the distribution of tracks. This might help to localize the origin of neutrons. By the way, unlike the (C) detector, the (E) detector was on that side of the tube where the vertical part of the platinum wire was located inside the electrolyte. The wire was only 2 mm away from (E) but 20 mm away from (C). Can this be significant? But questions like that are for later. At present the most urgent task is convincing others that CANA phenomena are real. How can this be accomplished? I suppose that many researchers are now trying to answer this question. My answer is; “by finding one simple to perform experiment that is very reproducible and by offering it to students.” That what I am trying to do. The next step will be to etch the chips that have been applied to the cathode (and to other cell components) after the electrolysis. I will do this after two more days of exposure.

December 7, 2004

37) I decided not to rush with processing the post electrolysis CR-39 chips. Let them accumulate tracks (if any) for several more days. Being curious in not a good reason to start etching too early. I will accumulate for seven days.

38) In a message sent to me today Richard wrote:". . . Today I completed electrolysis, etching, and cursory examination of the chips. The one under the Ni cathode has plenty of tracks, and two of the chips in the vapor over the electrolyte also have goodly numbers of tracks. I have not yet done a careful examination....." That is good news. i was less lucky in the first experiment at home. Is it possible that the reason for my failure was too short distance between the cathode and the CR-39 below? My distance was 1 mm while his distance was 15 mm, as before. This does not make much sense if track-creating particles come from nickel; I would see more of them, not less. But what if these particles are produced in air, due to something happening in the cell? In that case I would see practically no tracks. Next time I should return to the original distance of 15 mm.

In any other field the above mentioned tentative conclusion would be highly indicative. But in the field in which reproducibility can not be taken for granted everything is fluid. Nothing is really indicative to me here unless observed several time. And after that, as in the case of Oriani, one has to face hostility on the part of those who control publications in scientific journals. What a shame.

December 9, 2004
39) Nothing new to report, except that I found another teacher, over the Internet, who might be interested in replications of Oriani solid effect. I know, from frequent postings on the discussion list for teachers, that he is a very knowledgeable experimentalist and an excellent communicator. I will be happy to introduce him here, when he approves it. Working in parallel with several teachers is highly desirable, especially when phenomena are not 100% reproducible. The goal will be to develop a setup for student-oriented explorations. And, who knows, we may be able to discover something important.

December 13, 2004
My attempt to "popularize" Oriani cells (among teachers and students) by writing an article to The Physics Teacher failed. This is illustrated by the message from the editor of that journal (see below). It was a reply to my informal inquiry (see text qouted by the editor.)

Dear Professor Kowalski:
Our editorial staff has examined the discussion given at the URL provided in your message. While the materials required to conduct the Oriani (c) experiment might be accessible to schools, we believe that too few of our readers would consider the exercise to be appropriate for inclusion in their introductory-level physics courses. Because of space constraints, we are now able to publish fewer than one-third of the submissions we receive. We must therefore take care to select those which we believe would be of the greatest benefit to our readers. While we would be willing to review a completed manuscript of the sort you describe, we are not optimistic that it would be accepted for publication.

```

```

I am not happy; an anticipation of bringing Oriani's experiments to the attention of teachers and students is part of my motivation. I should be able to accomplish this, eventually. Such experiments are indeed ideal for exposing students to the excitement of scientific research. They deserve to be developed; they deserve to be published. I will not give up.

A crown of etching hooks (made from the 0.038 mm nickel wire and attached to a thick copper wire ring) forces me to drill a tiny hole in each chip. This is a delicate operation. The hole is used to suspend the chip from the hook. Is this method, copied from Oriani, is really better than dropping all the chips into my constantly stirred electrolyte? The answer depends on whether or not one believes that occasional scratches, and other surface defects, can be produced on the chips in the whirling electrolyte. The new method is great for removing the chips and placing the crown into water, if desired, at the same time. In about an hour I will end the first 6 hours of etching

and go to school to examine the chips. Then I might decide to etch for another 6 hours. The chips to examine have already been described in item 29 above. This time I did not forget to suspend a chip irradiated with alpha particles, my indicator of the quality of etching.

42) My "open letter" to scientists, who were chosen by the DOE to reevaluate cold fusion claims, was posted this morning; it is the unit #196. Will they be informed by somebody about my letter? Will they read it? Will some of them answer to my questions? I hope so.

43) I also nearly finished the self-imposed task of describing Fisher's polyneutron hypothesis. The already posted draft is going to be corrected, if necessary, by John Fisher. He complemented me for this work. The only suggestion, so far, was to change the name of the "element # zero." My choice for the name for the first element was Adamium (symbol A) but John prefers Neutrium (symbol Nt). He invented this element to explain the observed nuclear anomalies. The draft has already been posted as the unit #191. I will modify it after receiving Fisher's recommendations. What a strange set of speculations! The theory is simple; that is its advantage.

44) I examined all the chips (after 6 hours of etching) and decided to etch for another 6 hours. This is going on right now. Nothing convincing (at least 10 times above the background) tracks but seem to have smaller diameters than tracks seen on the chip irradiated with Am-241. I do not expect anything spectacular tomorrow.

December 14, 2004

45) Learn by making mistakes is not unusual. That what happened last night and today. I was anticipating to stop etching at 10 p.m. But I forgot about this and came one hour later. Etching for 13 hours instead of 12 is not a big deal. But something else happened. The temperature of NaOH was 73 C (instead of 65 C) and the level of the liquid was at 175 cc (instead of 200 cc). In other word, the chips were over etched by time, by temperature and by concentration. They were still transparent but had dull surfaces. Looking through them was like looking through a light fog. For a moment I thought that all was lost.

Fortunately, the chip that was irradiated with alpha particles was also over etched. I examined that chip and found about as many tracks of alpha particles as after the first 6 hours of etching. The circles ware larger than before; they often touched each other. Then I look at other chips and saw more tracks than I was able to count before (after 6 hours of etching). Distinguishing tracks of nuclear particles from dirt and surface irregularities became much much easier. It seems that that over etching is good, at least for my purpose, counting alpha-looking tracks. The control chip (background) also had more tracks that I was able to recognize before.

46) The second thing I learned by mistake was that examining a wet chips might be desirable. This has to be verified later, perhaps by using a liquid that does not evaporate as quickly as water. I had some dirt on the chip and decided to wash it before reexamination. The chip was not totally dry when I placed it on the microscopic slide. My magnification was 40. The impression I had was that some surface irregularities nearly disappeared when water was there. Will tracks be more recognizable when chips are coated with a thin layer of oil? That is worth exploring, when time becomes available.

47) Here are the results of counting, after 13 hours of etching:
.....
.....
I went to school to count tracks. But, after spending several hours at the microscope I found nothing significantly higher than the background, except in the chip J.

The conclusion from this experiment is that the expected effect was not confirmed (chips A and G showed no tracks above the background). Each of the chips F1, F2, F3 and F4 recorded about two times more tracks on one surface than on the other (and about three times more than in the background) but I do not trust myself on this. Why not? Because these chips were from AlphaTracks. That is the material that became foggy after over-etching, as I wrote earlier. The chips from Landauer were also over-etched but they did not become foggy. I think that AlphaTrack chips are OK for detection of alpha particles but they are not good for me. In the next experiment I will be using fresh Fukovi chips; they were sent to me today from Japan.

The only interesting results are those from the E and J chips where I really see at least ten times more tracks than in the background. The chip E was exposed to the outside wall of the upper tube during the electrolysis and the chip J was exposed to outside wall of the upper tube after the electrolysis. Both chips were from the CR-39 that Oriani used before he switched to Fukovi chips. They came from Italy; each chip is 1 mm thick. When E and J chips were applied to the tube I expected to see tracks on the surface facing the tube only. The other side was to be used to measure the background. But now I know that excessive tracks appear on both sides of E and J. It means I did have a control sample for the background in that material. I am now etching another chip; it will be my control sample tomorrow.

The question to answer is: "How many tracks are there on each surface of E and J and how do these numbers compare to the background tracks. Only then will I start speculating about neutrons (as I did above). Unfortunately my notebook does not say which side of the CR-39 chip was facing the glass. I had a rule about this: "scratched symbols should be on the side opposite to where particles are expected." But did I really follow that rule? I think I did, but am not sure. Tomorrow will be the last day of reporting, I hope.

December 15, 2004
OK, the experiment is over. I did not expect to turn a logbook for an experiment into a diary. But it was my first independently performed cold fusion experiment. I did not find what I was lookin for but an eqaully puzzling phenomenon was confirmed. A “nuclear signature”does come out of the lectrolytic cell but it comed through glass not through the nickel. Here are the results of today's counting.

Chop E: was in contact with the outside wall during the electrolysis (25 hours when the current was 0.30 A). The accessible surface area was about 0.45 square cm. The number of tracks on the side facing the tube was 580. Subtracting the background of 50 tracks (see below) one has the average detection rate of 47 tracks per hour, per square centimeter. The number of tracks on the opposite side (facing air in the room) was 48. This is the same as the background. In other words, my speculation about neutrons was not justified. But the anomalous tracks recorded by the detector E are real.

Chop J: was in contact with the inside wall after the electrolysis (175 hours). The accessible surface area was the same as for the chip E. The number of tracks on the side facing the tube was 169 This is only three times as much as the background. Taking the difference of 169 - 50 = 119 seriously, one finds the average detection rate of 1.5 tracks per hour, per square centimeter. It would be better, in this case, if I used Oriani.s method of subtracting the background. Is the emission of particles (from glass) after the electrolysis as real as during the electrolysis? I do not think so. My approach was too crude; I was looking for a strong effect. But I would probably have less trouble with 1.5 tracks per hour per cm^2 from nickel because the CR-39 chip placed below the cathode was from Landauer. The limit of detectibility would probably be 0.5 tracks per hour per cm^2

Chip Q: was my background for the same CR-39 as chips E and J (1 mm thick from an Italian supplier) and etched for 12 hours, as the other two chips (E and J). The number of tracks counted on one area was 53. The other area had a comparable number of tracks.

The bottom line is that the effect for which I was looking, nuclear particles in the detector placed below the nickel cathode, was not found. I used my best CR-39 (from Landauer) for the detector below the cathode, and for the measurement of the background. Other CR-39 chi were from two other suppliers. They were about as good as my better chips for the detection of alpha particles from ^{241}Am. I checked that. But I was not familiar with the background in chips from other suppliers. The unfamiliar material was used on something that was added in the last moment.

My failure to confirm tracks in the air below the cathode contrast with successes Oriani had after my departure from Minneapolis. Is it possible that my failure is caused by the absence of something that tap water has in Minnesota but not in New Jersey? I know what a skeptic might say. S/he would remind me that, at very low concentrations, alpha radioactive substances are always present in everything. And s/he would speculate that they might migrate in the electrolytic cell concentrating, for example, on the nickel or glass. Then they diffuse and become emitters of what one observes. But negative results, as Oriani likes to say, confirm that this does not happen. A skeptic can be criticized for not being consistent. If only 100% reproducible results should be taken seriously then contamination should also not be taken seriously.

Here are the pictures I took this morning, through the microscope.

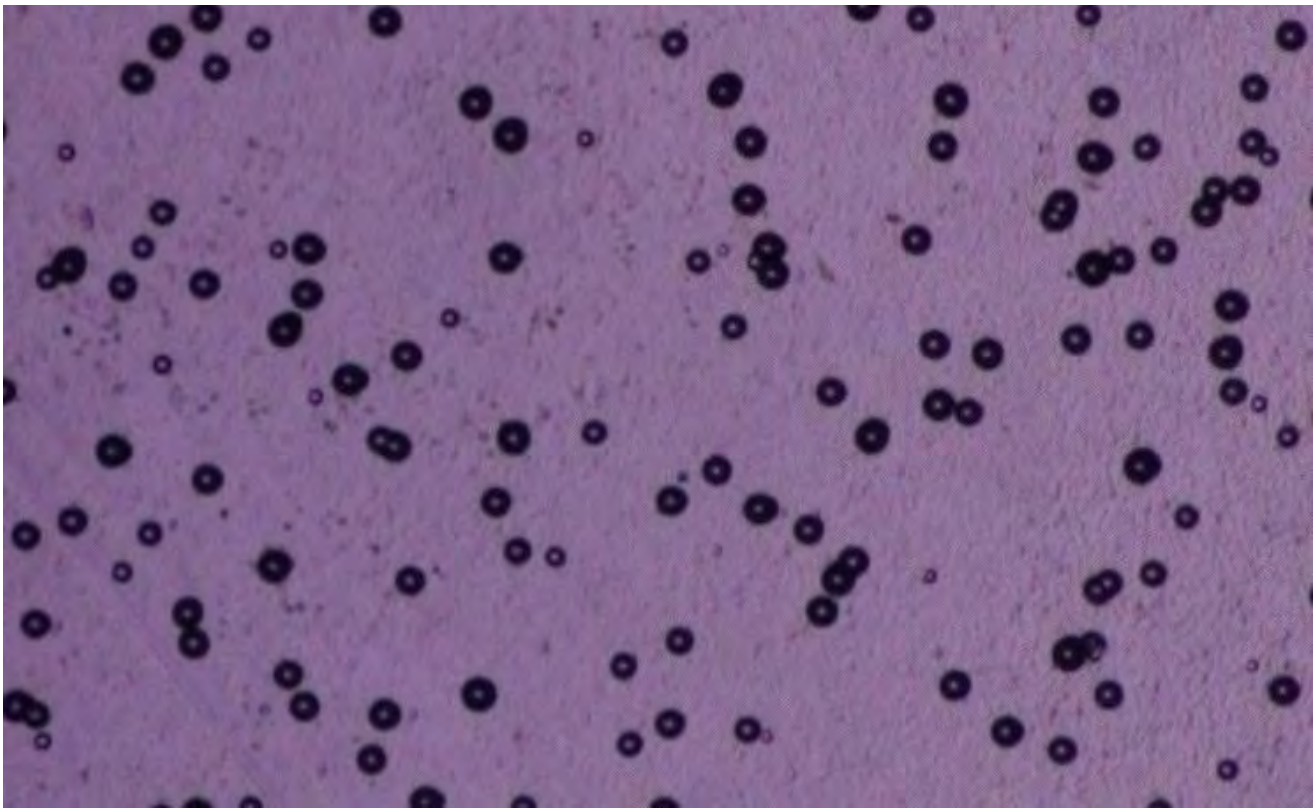

Figure 1 Alpha particles from a ^{241}Am source (in a little corner of chip Q)

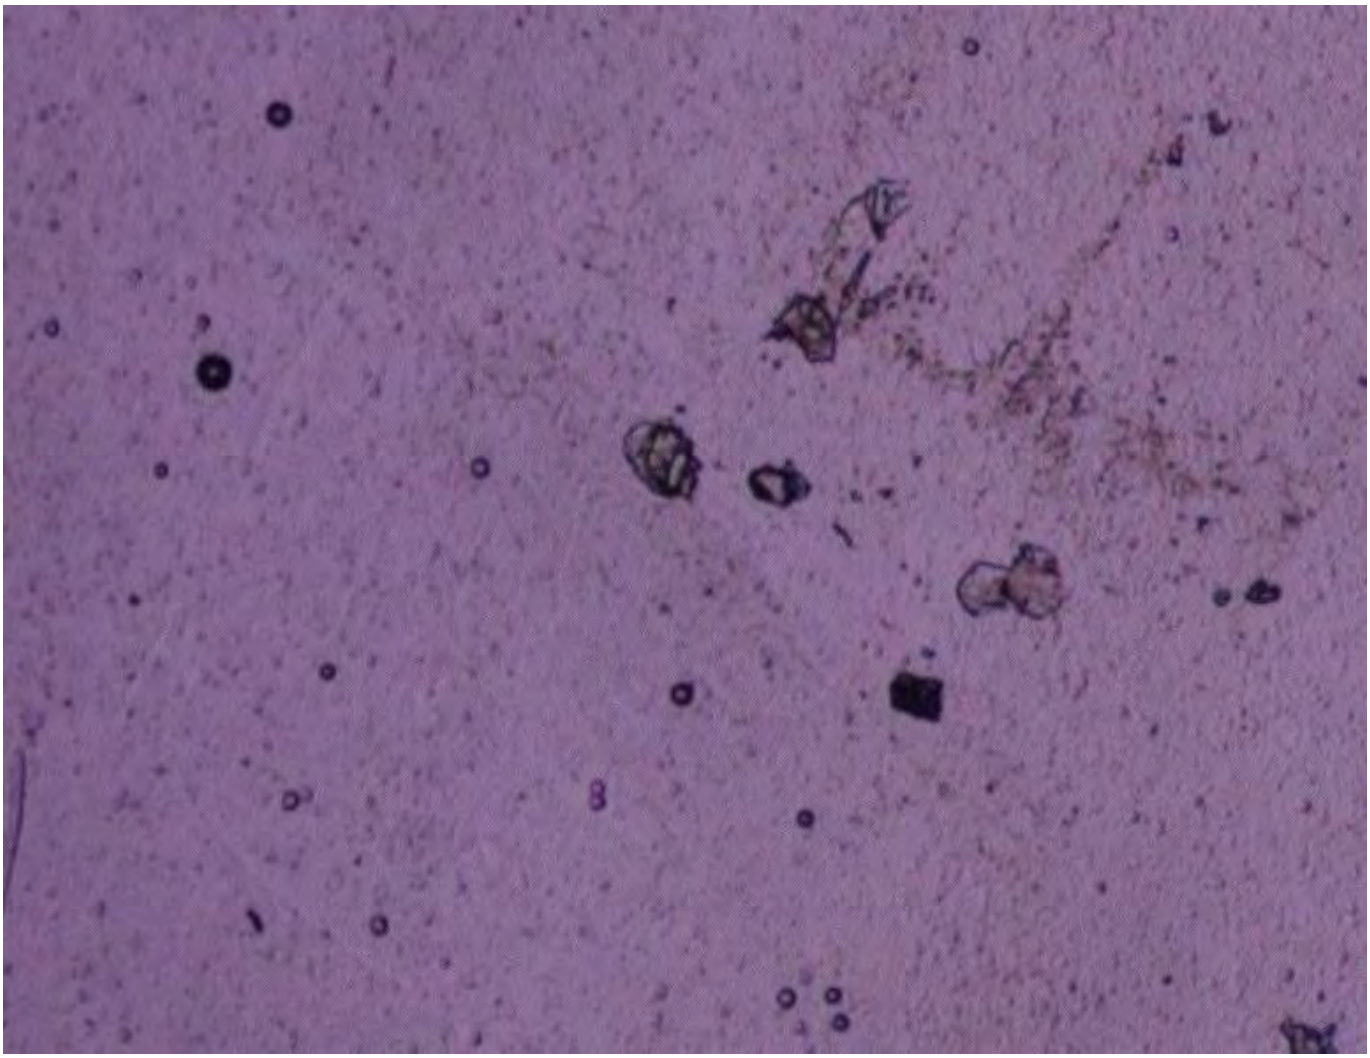

Figure 2 A typical background field (the other side of the chip Q). I suspect that most background tracks are due to cosmic protons, not radon. Detectors were protected from alpha particles in storage (by thin plastic covers).

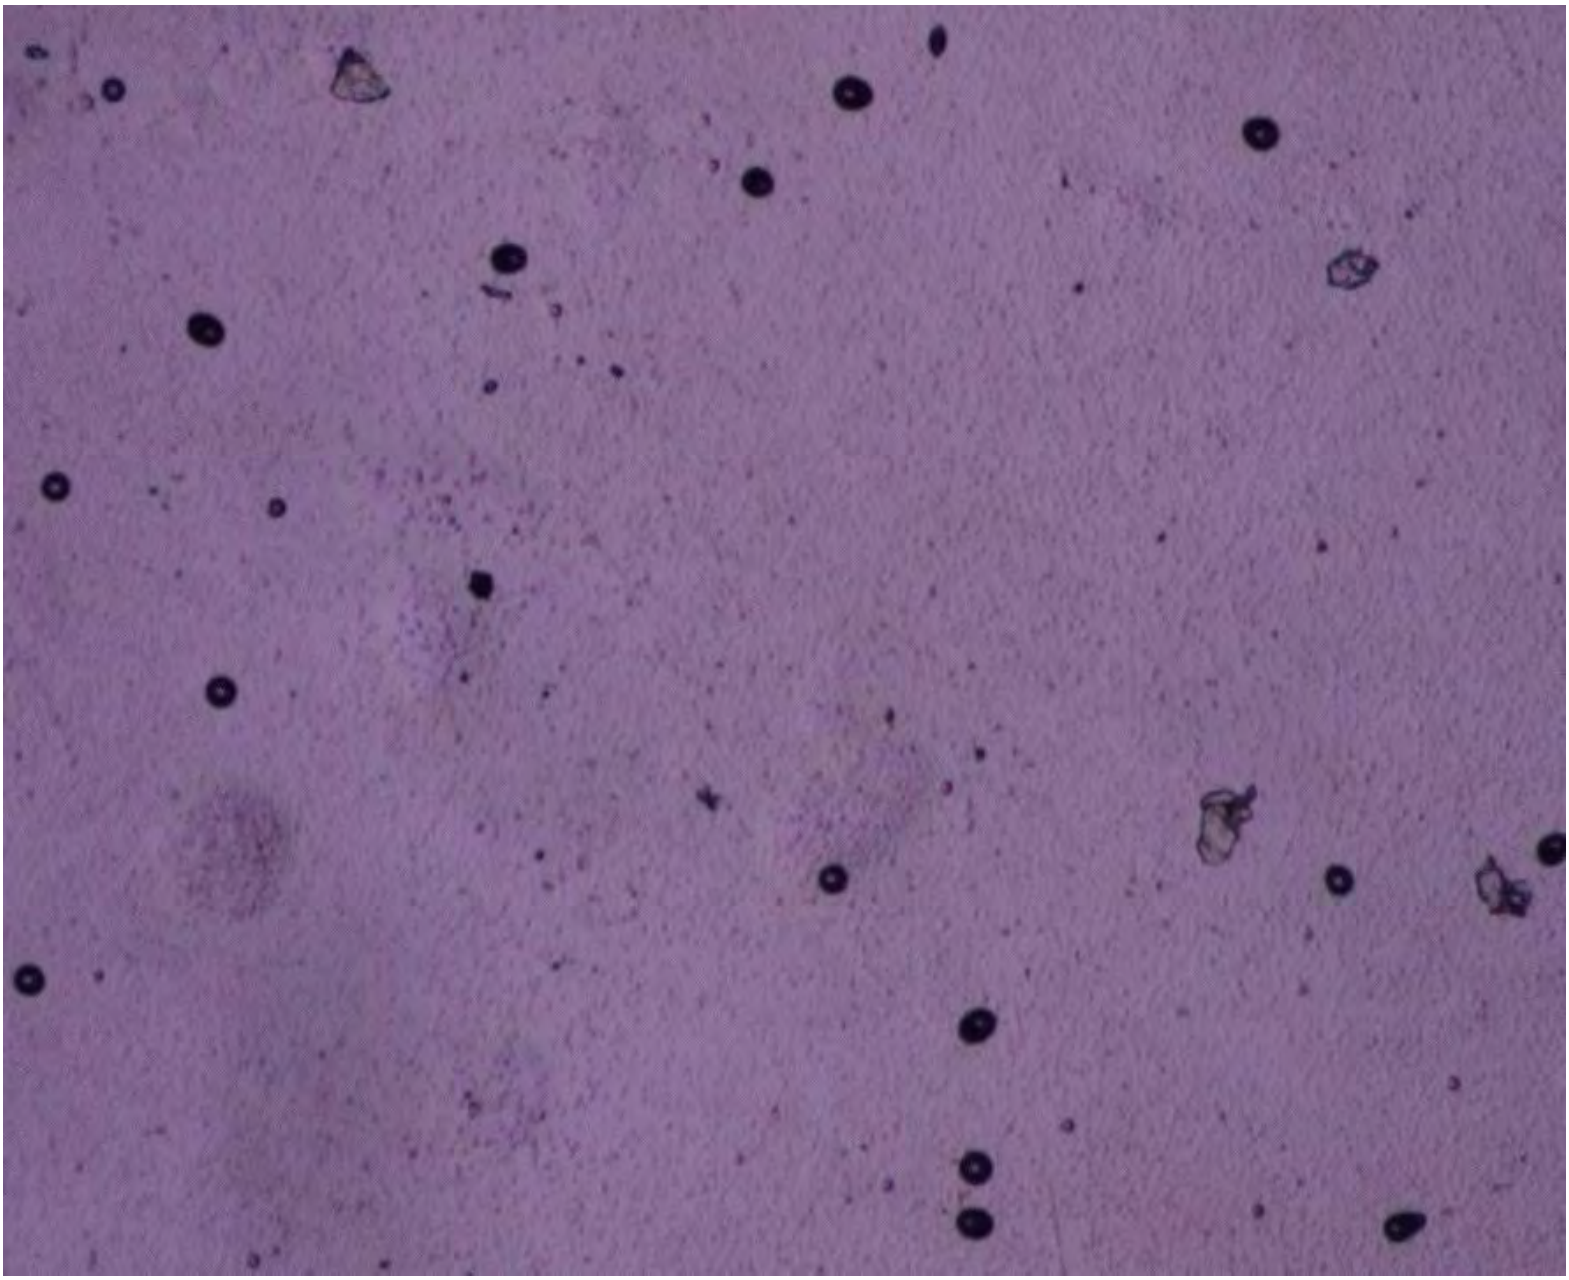

Figure 3 Tracks on the more active side of the chip E

The areas seen under the magnification 40 were 0.91 square millimeters each. But I trimmed the pictures to reduce sizes of files.

December 23, 2004
I am now in the middle of another experiment. It is going to be described in unit #197. But before going there let me say that an attempt to detect tracks in a Cr-39 chip that was applied to the glass after the electrolysis produced the negative result. The chip was in contact with glass for 85 hours. The particles were present during the electrolysis but not after the electrolysis. The experiment described in the unit #197 is going to end in about three or four days. Then many days of etching and examining CR-39. The last experiment described in this unit differed from the experiment we conducted in Minneapolis in two significant ways; that may explain negative results, as far as the CR-39 below the cathode was concerned. the differences were:

a) Oriani allowed concentration of the electrolyte from very low (at the beginning) to several times stronger (when a lot of water was lost). I was keeping the water level constant by adding water very often. My concentration was very weak all the time.

b) My anode was at a distance of about 15 mm from the cathode, his was about 5 mm. Furthermore, I had pulsating current, due to the accumulation of gasses below the platinum disk. In the experiment described in the unit #197 The current was again pulsing because the diameter of the anode was still too large. Oriani said that this should not be tolerated. Therefore I had to turn the current off, remove the anode and reduce its size even more. At the same time the distance between the anode and the cathode was reduced to about 7 mm. The whole operation took only 10 minutes (without removing the electrolyte) and pulsating current was eliminated. But this is part of the

next experiment.

Montclair State University, Upper Montclair, NJ, 07043

Dr. Mitchell Swartz, who I met at the last year's cold fusion conference (ICCF10), also has a site dedicated to cold fusion. This morning he emailed me a message (see below) with several links. I am posting them for your convenience. Please keep in mind that I do not feel competent conducting excess heat experiments. Measuring excess heat, produced at a rate smaller than one watt, is not trivial. Ruling out the non nuclear origin of such heat is very difficult. I am not a chemist. On the other hand, students should be encouraged to explore excess heat phenomena. Tasks of proving, or disproving, controversial claims, made by reputable scientists should be turned into educational projects. What can be a better way to expose students to the excitement of scientific research? Mitchell wrote:

Ludwik:
We have placed numerous links to your site, and would appreciate a link or two to JET Thermal Products. These are the links for JET Thermal Products which has on line teachings of how to reproducibly obtain cold fusion, and has an archive of information supplementing your site.

194) Comments about theories

Ludwik Kowalski (December 5, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

This morning I received an interesting message from an Israeli researcher, Boris Khachaturov, who I met at the last cold fusion conference. Referring to the Occam's Razor principle, and showing the URL below, he wrote:

http://en.wikipedia.org/wiki/Occam's_razor

". . . In any case, Occam's principle should be a guide to researchers trying to explain experimental facts. That is what I learned from my teachers. The principle is used, implicitly or explicitly, not only in science but in everyday life as well. I was surprised to discover that cold fusion researchers often ignore simple explanations of experimental facts and invent incredible "theories." Such theories are great brain teasers but they have nothing to do with what is actually observed in laboratories. Such treaties could easily be recognized among presentations at our cold fusion conference. But I am not saying that all theoretical presentations belonged to that category."

Yes, a theory that is simple is more desirable than a theory that is complicated, when both of them explain experimental facts successfully. But I am not sure which "simple explanations" are being ignored. Also, what might be simplier to one person might be more difficult to another. Does the concept of simplicity apply to the number of assumptions made to dervive a theory or does it apply to the mathematical sophistication of the derivation process itself?

In the unit #191, on this website, I am trying to describe my own understanding of the "polyneutron theory" of John Fisher. This work is in progress. The theory is rather simple, as far as mathematics is concerned. But its assumptions are far from being obvious. Do polyneutrons exist and do they have properties assigned to them by Fisher? Only experiments can answer this question. One has to admire those who invent theories explaining experimental facts. But tentative theories, in my opinion, should first be presented to people able to understand them. I did not see too many people able to understand the monopole theory defended at our conference. If I were the author of that theory I would not bring it to a cold fusion conference; I would bring it to a conference on electrodynamics, for example.

195) Oriani showers.

Ludwik Kowalski (December 3, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

The unit #188 was focused on Oriani sold effect. The Oriani Liquid and Oriani Gas effects were mentioned in it but not elaborated upon. John Fisher, whose polyneutron theory (to be described the unit #191) provided motivation for placing CR-39 detectors into the vapor phase, and who collaborated with Richard Oriani, sent me the pdf file describing their work. The paper focuses on showers of particles in vapors. Description of that experimental work has been available, for more that a year, from the library at:

html://www.lenr-canr.org

The URL for the file that John Fisher sent me (on 12/1/04) is:

http://blake.montclair.edu/~kowalskil/cf/bigshower.pdf

Enjoy reading this paper, and other important contributions made by these two scientists. In giving me his permission to make the file downloadable from my list Richard Oriani wrote that he is thankful “for making our paper available through another channel, particularly because publication of this paper in physics journals was not possible.“ Publishing a report in this area, even by high caliber scientists, is much more difficult than publishing a report in another area of physical science.

196) Open letter to the DOE and its team of 18 scientists

Ludwik Kowalski (December 11, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

1) This unit (a set of questions) was prompted by a recent note entitled "US Review Rekindles Cold Fusion Debate." Written by Geoff Brumfiel, from Nature, it was published on12/2/04.

<http://www.nature.com/news/2004/041129/full/041129-11.html>

The author wrote: "Claims of cold fusion are intriguing, but not convincing. That is the conclusion of an 18-member scientific panel tasked with reviewing research in the area. The findings, which were released on 1 December by the US Department of Energy, rekindle a 15-year-old debate over whether nuclear fusion can occur at room temperature."

I do not know any scientist who claims that useful energy can be produced from fusion of two isolated deuterium nuclei at a room temperature (ignoring Coulomb barrier). That was the major topic of concern 15 years ago. The new DOE panel was expected, as far as I know, to evaluate claims of selected nuclear anomalies, such as generation of helium, or emission of 3 MeV protons, that were not know in 1989.

2) Broomfield wrote that "According to the report, the panel was split approximately evenly on the question of whether cold fusion experiments were actually producing power in the form of heat." Is it not true that in science controversies are resolved through better experiments rather than by counting how many experts are for and against competing claims?

3) Were you, the members of the panel, offered opportunities to visit laboratories of cold fusion researchers in order to participate in decisive experiments, or to personally observe and criticize them?

4) According to the DOE report your conclusions were reached on the basis of one review paper (and interactions with selected cold fusion researchers during a one-day meeting). I would like to know if, in addition, some of you tried to replicate selected experiments in your laboratories. If so, then please share your findings.

5) Did you request anonymity or was it the DOE initiative to remove your names from individual reports? I am probably not the only one interested in your names and affiliations. As you know, scientific publications are usually signed -- for good reason. Who among you were "nine additional scientists chosen by DOE for their expertise in relevant fields"? Who among you are experts on detection of helium, at low concentrations?

6) Four months before the second DOE report was published I addressed you, indirectly, in the form of a Letter to the Editor of Physics Today (published on page 14 in the September 2004 issue). I asked: "Is there any indication that leading cold fusion scientists are incompetent or that their data are fraudulent? Is the research methodology that cold fusion scientists use different from that used in other areas of physical

science? Answers to these questions will help me decide what to think about cold fusion and what to tell students about it." The title of my letter was "Seeking Answers From Cold Fusion Review." Why was the issue of competence and honesty not mentioned in the DOE report? I expected it to be addressed in view of commonly used epithets, such as "bad science," "voodoo science," and worse. A clear statement about qualifications of those whose work was investigated would be extremely useful in the context of existing accusations and attitudes.

7) I agree with you that "claims of cold fusion are intriguing, but not convincing." Experiments must be 100% reproducible to be convincing. But that does not mean they are fraudulent, or that they belong to voodoo science. Electrostatic experiments were also irreproducible before the role of humidity was recognized. That is why more research is needed. The biggest obstacle is negative publicity. You had a chance to decisively remove that obstacle. But you did not take advantage of that opportunity. What should be done now to help the honest and qualified scientists who are currently exploring the intriguing aspects you mentioned in the report? Conditions of their work are highly abnormal; what can be done to improve them significantely?

8) I would be happy to post your replies here; they will be seen by many interested (and often very qualified) readers. Your replies are likely to become important historical documents, no matter how the issues are resolved in the future.

9) Let me finish this open letter by introducing myself. After teaching physics for more than three decades, at Montclair State University in New Jersey, I retired and became an independent researcher. I was trained as an experimental nuclear physicist (Ph.D. 1963, University of Paris, France) and am now happy to be an investigator of LENR phenomena.

P.S. (12/12/04)

10) I believe that your reason for addressing the issue is not different than mine; we want to see the LENR controversy resolved, one way or another. I also think that it is premature to speculate about practical applications; the emphasis should be on scientific aspects of anomalous phenomena, not on benefits they might possibly offer. Technological explorations will follow naturally after anomalous effects are recognized as real; and after normality is established.

11) In the DOE report I read: "Results reported in the review document purported to show that ^{4}He was detected in five out of sixteen cases where electrolytic cells were reported to be producing excess heat. The detected ^{4}He was typically very close to, but reportedly above background levels." Were all sixteen experiments conducted by equally qualified researchers?

In any case, such experimental results are highly significant; total absence of nuclear byproducts (ashes) was one of the most convincing arguments against the suggested nuclear origin of excess heat. That is why I took the 1989 DOE report very seriously. On the basis of your observations, I would say that a tremendous progress was made on the issue of "missing ashes."

12) I am disappointed that additional experiments were not performed by experts among you to clarify the situation, for example to show that the effects are not due to contamination. I would very much prefer to have a delay of one year, if necessary, than a timely report stating, essentially, "on one hand this and on the other that." An old joke about a one-handed lawyer came to my mind when I was reading the second DOE

report. For everything positive in the DOE report there is an immediate negative, and vice versa. How can such report help us to form a valid opinion about what has happened in the LENR field in the last decade? As experts you are in a much better position to address the contradictions than most of us.

13) And here is another reason to be disappointed. The new DOE report states: " To explain these unusual characteristics, the reviewers were presented with a theoretical framework that purported to describe how collective energy from the material lattice couples to a deuteron pair to induce fusion, how the only fusion reaction channel that occurs would be the production of ^{4}He, and how all the energy is coupled back into the material in the form of heat instead of high energy gamma-rays. The reviewers raised serious concerns regarding the assumptions postulated in the proposed theoretical model for the explanation for ^{4}He production."

Generation of helium from deuterium is anomalous because it can not be explained by accepted theoretical models. I agree that our textbook models must be taken very seriously because they have been confirmed by highly reliable experimental data. You are not alone in thinking that attempts to develop a better theoretical model (presumably explaining generation of ^{4}He) are far from being totally satisfactory. But why should this weaken our confidence in the experimental fact itself? Why was the weakness of a new model mentioned in this context? Yes, I know, the field is blind without a theory to guide it. But wouldn't you agree that establishing validity of experimental facts is even more impotrant, at this stage?

14) According to the last paragraph of the DOE report "material science aspects of deuterated metals using modern characterization techniques could be helpful in resolving some of the controversies in the field." That is certainly true. But use of commonly available, and much less expensive, tools should also be encouraged, especially among students. To prove, or disprove, a controversial claim can be an educational project. What can be a better way to expose students to the excitement of scientific research?

197) Second Oriani experiment in my lab

Ludwik Kowalski (December 23, 2004)
Department of Mathematical Sciences
Montclair State University, Upper Montclair, NJ, 07043

One can consider this to be a continuation of my unit #192. That was open electronic logbook that turned into a diary. I am going to be much more concise in this description. I am using the same cell but the CR-39 is from Fukuvi. At the end of unit #192 I explained why my previous experiment should not be considered as a replication of what was described in the unit #188.

Description of electrolysis:

a) 23 hours at the nominal current of 100 mA (pulsation due to bubbling)

b) 24 hours at the nominal current of 200 mA (pulsation due to bubbling)

c) Current was cut off for 10 minutes to bring the anode closer to the cathode and to reduce the anode diameter. This was necessary to eliminate pulsation).

d) 33.5 hours without pulsing. The current was growing slowly from 200 mA to 375 mA, as water was decomposed and the concentration of the electrolyte ~doubled).
Then water was added to return to the original concentration.

e) 14.5 hours without pulsing. The current was growing slowly from 375 mA to 510 mA, as water was decomposed and the concentration of the electrolyte ~doubled).
Then water was added to return to the original concentration.

f) 18.5 hours without pulsing. The current was growing from 350 mA to 600 mA, as water was decomposed and the concentration of the electrolyte ~doubled. Then water was added to return to the original concentration.

g) 16 hours without pulsing. The current was growing from 350 mA to 600 mA, as water was decomposed and the concentration of the electrolyte ~doubled. Some water was added after 12 hours to prolong the high concentration run. Then water was added to return to the original concentration.

h) 18 hours without pulsing. The current was growing from 350 mA to 600 mA, as water was decomposed and the concentration of the electrolyte ~doubled. Then water was added to return to the original concentration. **At this point I accumulated 102.5 hours of normal electrolysis (after 47 hours of the electrolysis with the pulsating current).**
A potential problem: I must address the issue of concentrations of the electrolyte. Both Oriani and me start from the same concentration (2.36 grams of Li_2SO_4 salt per 100 cm^3). But my tube (total length above the cathode) is 7 cm while his is about two times longer. I must add the liquid when the level is 3.5 cm above the cathode (to have nearly 1 cm cover above the cathode. In going to that level the volume of my liquid is reduced by a factor of 3. It means my concentration increases by the same factor when water is decomposed. In longer tube the concentration changes by the factor of 4 or 5. This implies that some concentrations used by Oriani were never tried in my cell. In trying to replicate his findings I must run electrolysis at higher concentrations. To triple my minimum concentration, for example, I must add 2*0.29 = 0.58 grams of the salt before filling the tube to the rim.

But I have no scale at home. However my bottle with originally prepared electrolyte is not empty. Instead of adding pure water (as I do when the minimum level is reached) I will add the original electrolyte. This will add 0.19 grams of the Li_2SO_4, salt. (minimum concentration will increase by the factor of 1.65, doing it twice will increase it by the factor of 2.3 and doing this three times will increase it by the factor of 3.0. And one more dose of 019 grams of Li_2SO_4, would make the factor equal to 3.6. That is what I am going to do from now on -- refilling with the electrolyte instead of water. This will not take away racks that have already been accumulated so far in 150 hours. Who knows, perhaps the secret of success is in using high concentrations?

Yes, I know that ideally everything should be as constant as possible in a single experiment. Then one could change one parameter, for example, the current or concentration, and repeat the experiment. And that is what i might start doing when the goal will be to understand and to optimize. But for the time being the goal is to convince myself, and others, that the discoveries made by Oriani are real and worth focusing on. His philosophy is to scan over different currents and concentrations in order to approach 100% reproducibility. I am following this philosophy.

i) Add one dose of 0.19 grams of salt and run the cell for **4 hours** at the nearly constant current (0.55A to 0.65A) to bring the level of the liquid to its minimum before the end of the day. After these 4 hours one of the two CR-39 pieces was removed from the inside of the cell. It was the chip K (Scratched cross was at the bottom; it was not facing the second immersed piece).

Also one pair of CR-39 touching the tube from the outside was removed. The piece facing the tube was G (cross and G are at the top, the side facing the cell was the one that had G and the cross). The other removed piece was L. It was behind the piece G. The cross and the L were near the top, as on the piece G. The side with L on it was in contact with the piece G. A fresh single CR-39 was placed to replace the G+L pair.

j) Add the second dose of 0.19 grams of salt and run the cell **for 12 hours**. During that time the current was changing from 020A to 0.25A in 5 hours and then kept more or less constant near 0.6A for another 7 hours.

k) Add the third dose of 0.19 grams of salt and run the cell **for 12 hours**. During that time the current was around 0.25A for the first 5 hrs and around 0.6A in the remaining 7 hours.

l) Add the fourth (and last) dose of 0.19 grams of salt and run the cell **for 15 hours**. (starting on 12/27/04 at 13:00). During that time the current was around 0.30A for the first 5 hours and around 0.6A in the remaining 10 hours.

m) Add pure water and run the cell **for 12 hours**. During that last electrolysis step the initial current was 0.35A and the final current was 0.6A.

The electrolysis will be stopped after that. Then fresh CR-39 chips will be applied to each side (“was dry” and “was wet”) of the Ni cathode. Perhaps absence of tracks during the electrolysis (I hope they will not be absent) does not mean that no tracks can appear later.

Description of detectors in and around the cell:

The exposed CR-39 area is about the same as in the experiment 192. But the area surrounding the tube is about 50 times larger than my single chip in experiment 192. That single chip caught a lot of tracks (more than ten times above the background) during the electrolysis but nothing after the electrolysis (as described at the end of the unit #192). I am focusing on tracks that Oriani discovered outside the tube. The tube is surrounded by large pieces of CR-39, as illustrated in Figure 1. The piece facing us is 5 cm long and 1 cm wide. Actually it is a set of two pieces, one behind the other. The “cover”, also a set of two pieces, is exposed to the escaping gases during the entire electrolysis. The set of two pieces might be able to detect neutrons, if enough of them are emitted to create recoiling protons. Note the holes drilled in CR-39. They will be used to suspend the pieces from thin nickel wire hooks during the etching (in hot NaOH).

FIGURE 1

I will describe and label these pieces in the next section. Two large CR-39 pieces, not visible in the illustration, were inserted into the electrolyte, above the anode. The level of the electrolyte changed due to decomposition of water. Therefore, only lower parts of the inserted CR-39 pieces are always in the electrolyte. The upper part of the inserted pieces are always exposed to escaping hydrogen and oxygen vapors. Middle sections are sometimes in the electrolyte and sometimes in the vapors. There is also a piece sitting near the top of the tube (without blocking the escaping H_2 and O_2).

The entire outside area of the upper tube (28 cm^2), is exposed to CR-39. This is 62 times larger than the area covered in the last experiment. Likewise, the duration of the electrolysis is nearly three times longer. Therefore, my chance of observing particles emerging from the tube (I observed their tracks in the last experiment) is much higher now than before. And about 20 cm^2 of the exposed CR-39 area inside the tube should reveal particles that Oriani observed inside the electrolyte.

Labeling of CR-39 pieces:

1) Chips A, B and BB will tell me if the outside wall of the tube, where tracks were discovered in my first experiment (see the unit #192), is still active when the this second experiment started.

2) Chip BBB is my background control sample.

3) **Chips C and Pcrossed** were in the air below the cathode during the entire 202.5 hrs of electrolysis. The chip C was looking at the Ni cathode (with its unlabeled side) while the chip Pcrossed was looking at the chip C from below. The labeled side of the chip Pcrossed is looking down toward a wooden cylinder supporting it.

4) **Chips I and J** were a pair making a “cover” above the cell. Chip I was looking down to the rising vapors (with its shinny side); The shiny side of the chip J was also looking down, thought the chip I. The labeled sides of both I and J were looking up. Both of these were used during the entire 202.5 hrs of electrolysis.

5) Chips D and M, both large, stand along the vertical glass wall of the tube. Chip D touches the glass with its shinny side, chip M touched the chip D with its shinny side. Both of these were used during the entire 202.5 hrs of electrolysis.

6) Chips E and N, both large, stand along the vertical glass wall of the tube. Chip E touches the glass with its shinny side, chip N touched the chip E with its shinny side. Both of these were used during the entire 202.5 hrs of electrolysis.

7) Chips H and O, both large, stand along the vertical glass wall of the tube. Chip H touches the glass with its shinny side, chip O touched the chip H with its shinny side. Both of these were used during the entire 202.5 hrs of electrolysis.

8) Chips G and L, both large, stand along the vertical glass wall of the tube. Chip G touches the glass with its shinny side, chip L touched the chip G with its shinny side. These two chips were removed before the step (i) of the electrolysis. In other words, they were collecting tracks only during the first 147.5 hours of electrolysis.

10) Chips F and K were suspended into the cell (crossed labeled down). F remained in the cell during the entire duration of the electrolysis (202.5 hours) while chip F was removed before the step (i), after 147.5 hours. Chip F was replaced by the chip S that remained in the cell for 50 hours (when the concentration of the electrolyte was increased and when larger currents started to be used).

11) Chips P, Q and PP were also used; I will describe their purpose only when it becomes necessary. were also standing along the tube walls.

12) Chips used after the electrolysis will be described later.

Yes, I know that ideally everything should be as constant as possible in a single experiment. Then one could change one parameter, for example, the current or concentration, and repeat the experiment. And that is what I might start doing when the goal will be to understand and to optimize. But for the time being the goal is to convince myself, and others, that the discoveries made by Oriani are real and worth focusing on. His philosophy is to scan over different currents and concentrations in order to approach 100% reproducibility. I am following this reasonable philosophy. What would be the purpose of changing one parameter at a time when outcomes of consecutive experiments are very different, even when controllable parameters are not changed?

Etching, observations, reflections, etc.

1) The figure below shows tracks due to alpha particles from an 241Am source. The chip, etched at the same time as that shown in Figure 3, was dirty. But, as one can see, dirt, scratches and other surface defects can easily be distinguished. The lower left corner is the chip boundary. Ambiguities in tracks counting are minimized when chips are handled carefully, and when they are washed after etching.

FIGURE 2

2) Without ending the electrolysis I removed three large CR-39 chips, K, G and L (after 147.5 hours) and etched them. The area of each chip is about 5 cm2. The chip K, that was suspended into the cell, was at once replaced by a fresh chip S. The average densities (based on random sampling of fields), were between 300 and 700 tracks per cm2 The nominal background density is about 10 tracks per cm2. The distribution of tracks was found to be clearly nonuniform. Clustering of tracks is illustrated in Figure 3. It is a photo of 18 tracks in the field of view whose area is 0.7 square millimeters. The four adjacent fields (of the same size, on the left, right, above and below) had zero tracks. Of the four diagonally nearest fields two had no tracks and two had one track each.

FIGURE 3

3) The electrolysis ended after 202.5 hours and all chips were etched. During the last 50 hours the concentration of the electrolyte was increased and currents up to 0.7A were used (instead of the up to about 0.35A before). The cathode was removed and sandwiched between two CR-39 chips. Likewise, chips were applied to the anode and to the electrolyte removed from the cell. Will these control chips also display particles, after I etch them in several days? I will let you know.

4) Chip S (that replaced the chip K inside the cell) was found to be covered with more particles (also clustered) than the chip K. More specifically, the average track density on two surfaces of the chip K (after 147 hours a accumulation) was about 520 tracks per cm2 (or 3.5 tr/cm^2 per hour). For the chip S, on the other hand, the average track density on two surface (after 147 hours a accumulation) appears to be at least two times higher. That seems to indicate that using more concentrated electrolytes, for example 0.5 M or above, and larger currents, is desirable.

5) And what about the tracks on chips D, E and H that were facing the glass walls of the tube? Each of these chips revealed clustering of tracks, similar to those shown in Figure 2. The same was seen on the chip Q that was used to replace the chip G. Facing this situation I am inclined to anticipate that anomalous tracks are likely to be 100% reproducible in setups similar to that shown in Figure 1. Please write to me <kowalskil@mail.montclair.edu> about your own attempts to replicate Oriani's experiments; I will append your message to this webpage. Let me add, however, that quantitatively, results are not yet consistent. Additional experiments, preferably performed in different laboratories, are needed. The topic is too big for one or two people; your help will be highly appreciated.

6) As you may recall, my first experiment (see the unit #192) failed to confirm presence of nuclear particles in the air outside the cathode. Were I able to detect such particles in this experiment? The 1 cm2 chip, placed below the cathode, did record 28 particles in 202 hours of electrolysis . The method I am using is not appropriate for making decisions about very low recording rates. I do not know why the average recording rate was much higher in the experiment performed at Minneapolis (see the unit #188).

! ! ! P.S. (12/30/2004) ! ! !
Please suspend your judgment about the preliminary results described above. I just discovered that something alpha-radioactive might have been sporadically deposited on some of my CR-39 chips, when they were etched in the hot solution of NaOH. The entire experiment must be repeated, after the source of the contamination is identified and eliminated. I still believe that what I wrote above will be confirmed, at least qualitatively. But how can I be certain about this now, after discovering a lot of tracks on my both blank control samples? More about this later.

7) Tomorrow I will etch several control samples. The goal is to convince myself that blanks chips do not display any tracks after I stop suspending them from the thin telephone wires. I suspect that insulation of that wire released something radioactive. Perhaps it was uranium or thorium in a dye used for color coding. In most cases, but not always, the plastic insulation was was removed. In any case, I will etch the following chips:

Chip A: "blank" that was exposed to the air in the room for two weeks.
Chip B: "blank" that was also exposed for two weeks but in another area.
Chip C: "blank" that was exposed to the air in the room for about 0.5 hours only.
Chip D: was exposed (50 hours) to the plastic cover of the telephone wire.
Chip E: was exposed (50 hours) to the copper of the telephone wire.

Chip F: was exposed (10 seconds) to alpha particles from 241Am (at one end only).

Chip G: was exposed (50 hours) to the electrolyte after the electrolysis.
Chip H: was exposed (90 hours) to the nickel cathode after the electrolysis (dry side)
Chip I: was exposed (90 hours) to the nickel cathode after the electrolysis (wet side)
Chip J: was exposed (90 hours) to the platinum anode after the electrolysis.
Chip K: was exposed (90 hours) to the inside glass wall after the electrolysis.
Chip L: was exposed (90 hours) to the outside glass wall after the electrolysis.
Chip M: was exposed (90 hours) to the black plastic holder of chips used in etching.
Chip N: was exposed (50 hours) to the blue plastic sleeves in the crown of hooks.

Hopefully, the first three chips will show no contamination in the air or in the etching solution. The next two will test my hypothesis that contamination came from the plastic cover and not from the copper wire. (But the hypothesis assumes that contamination was released at 70 degrees C, during the etching, while the plastic cover was exposed to the CR-39 at room temperature. The test might turn out to be nonconclusive.) The chip F is my usual calibration test, to make sure that etching itself was sufficient. It is convenient to have F available to recall the appearance of alpha tracks, when in doubt. The last eight chips will tell me whether or not the cell is ready for the next experiment. Hopefully, these eight chips will show about as many tracks per unit area as chips A and B.

P.S. (1/2/05)
Yes, a lot of tracks were found on the chip D while the chip A had at most 3 tracks per square cmentimeter. I was lucky; the test was conclusive.Finding a source of weak contmination in a system made from many different materials can be a formidable task, unless the source is strong enough for a simple Geiger counter.

The more exciting, and puzzling, are huge numbers of tracks on chips H and I. Why did I not see tracks below the dry nickel cathode during the 202 hours of electrolysis? Why did I see a lot of them in 90 hours immediately after the electrolysis? There are only two explanations of this, as far as I can say: (a) Particles producing tracks were stopped in 6 mm of air (before reaching the CR-39) and (b) the foil started emitting particles after the current was turned off (or shortly before that). The first explanation is in conflict with the experiment i performed with Oriani, and with his subsequent experiments; the distance of 6 mm was chosen to match his distance. The second explanation is “hard to accept” but that is a matter of psychology, not physics. More about all this later.

I just started another accumulation of tracks from the used nickel cathode (another set of chips H and I) and from the glass wall (another set of chips chips K and L). Will I confirm Oriani’s observation that the rate of tracks accumulation

is decreasing in times? Will this decrease be exponential? What will the half-life be? That remains to be seen.

P.S. (1/4/05)
The second accumulations mentioned above ended today and third accumulations started, for both nickel and glass. Oriani sent me his numbers of tracks/cm^2 per hour. They are consistant with the half-life of about 10 days. Will my accumulations confirm this? I looked at information about daugthers of radon and thoron. Nowhere could I see the half-life close to 10 hours.

Here is a trivial problem: "Knowing the half-life of a radioactive isotope calculate how many atoms must be present to emit 100 particles per hour (Activity = 100 per hour)?"

T = 10days = 240 hours ---> lambda = ln2/T = 0.69/240 = 0.029 per hour

A=lambda*N ---> N = A / lambda = 100/0.029 = 34624 atoms.

This is an exceedingly small number of atoms. A piece of dust, I suppose, can be expected to contain that many atoms of any element of the periodic chart. Yes, I know, it is too early to speculate that we are dealing with some kind of induced radioactivity. The only thing we know is that charged nuclear particles are present, even after the electrolysis, and that the average rate of emission, initially on the order of 100 per hour (in all directions) decreases it time. I have no idea what can cause this, except a radioactive substance.

My results (first post-electrolysis analysis, called "experiment #3'):
Chip A: Blank Only two or four tracks per square centimenter.
Chip B: another blank, but with 300 tracks/cm^2. Perhaps the metal box in which it was kept (?) contained something. In any case, this translates to 3.3 tracks/cm^2 per hour. I am still learning; a blank control chip must be handled in the same way as other detector chips, except for the electric current. Next time I will place it into the electrolyte together with the platinum wire, and the scraps of my nickel foil.
Chip C: another blank, clean as A above.
Chip D:: plastic cover over the copper wire. On the average 110 tracks per 0/044 cm^2. This translates into 50 tr/cm^2 per hour. The spiral pankake of wire was placed on the top of a chip for 90 hours. That is very high recording rate.
Chip E:: Copper wire. Some tracks were recorded in 90 hours.
Chip F: 241Am tracks are a large and easy to identify. Etching time was just right.
Chip G: Chip placed into the electrolyte for 50 hrs. About 2 tracks/cm^2 per hour.
Chip H: Chip on top of DRY nickel for 90 hours after the electrolysis 23.1 tr/cm^2 per hour. This is comparable to what Oriani observed. That is my first post-electrolysic exposure; two more will be etched and analyzed in three or four days. But Oriani also saw tracks accumulating diring the electrolysis. Why did I not see them? That is a big puzzle.
Chip I: Chip on top of WET nickel for 90 hours after the electrolysis. 17.7 tr/cm^2 per hour. This is also comparable to what Oriani observed.
